'REACH-IN': USING THE INPATIENT ENCOUNTER TO EXPAND ACCESS TO PRIMARY CARE-BASED TREATMENT FOR OPIOID USE DISORDER

Trevor G. Lee; Michael Herscher; Reema Navalurkar; Leeza Hirt; Matthew Fine; Dillan Villavisanis; Benjamin Shuham; Jeffrey Weiss; Stacey Rubin; Linda Wang. Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3186383)

BACKGROUND: Maintenance opioid agonist therapy (OAT) with buprenorphine reduces mortality and is a well-established treatment for opioid use disorder (OUD). Despite the availability of effective therapy, approximately 80% of persons with OUD do not receive it. Patients with OUD represent an estimated 4-11% of hospitalized patients and are increasingly admitted for opioid-related complications. The inpatient encounter represents an opportunity to begin OAT and coordinate continued treatment in the primary care (PC) setting. Prior research has demonstrated that in-hospital buprenorphine initiation with linkage to outpatient care is associated with increased engagement in care and decreased opioid use.

METHODS: REACH-IN is a quality-improvement program to expand access to OAT by identifying hospitalized adult patients with OUD, initiating buprenorphine, and facilitating the transition to

outpatient care at REACH, a PC-based program that offers buprenorphine. Based at a large, urban hospital, REACH-IN identifies eligible patients in two ways: 1) a daily electronic report of inpatient or emergency department encounters that documented opioid use, and 2) direct referrals from providers. Eligible patients were evaluated, started on buprenorphine if appropriate, and titrated to a stable dose. All evaluated patients were offered a facilitated transition of care to REACH post-discharge. This involved meeting with REACH staff for a "warm" hand-off prior to discharge, receiving care coordination from a patient navigator, and being scheduled for a buprenorphine intake appointment within one week.

RESULTS: From April 23, 2018 to January 10, 2019 we screened 1589 encounters, 1559 (98.1%) of which were identified via the report, 30 (1.9%) via direct referrals. Of these, 855 had been discharged by time of screening. Of the remaining 734, 43 (5.9%) patients were evaluated, 11 (25.6%) of whom were started on buprenorphine in the hospital. Of the 32 who were not started, 16 (50.0%) were referred to REACH, 4 of whom eventually started buprenorphine. Four (12.5%) were referred to another OAT program. Of those started on buprenorphine in the hospital, 5 (45.5%) attended an initial outpatient visit at REACH, 5 (45.5%) were referred elsewhere for ongoing OAT, and 1 remains hospitalized, with 8 (72.7%), 5 (45.5%), and 4 (36.4%) engaged in treatment at 30, 60, and 90 days, respectively.

CONCLUSIONS: Inpatient hospitalizations represent a 'reachable moment' to identify patients with OUD, initiate buprenorphine, and facilitate the transition to continued PC-based treatment. As hospitals see increasing numbers of opioid-related admissions, a structured partnership and facilitated transition between inpatient and outpatient providers may help expand access to OAT and increase engagement in care. These data provide preliminary evidence for the feasibility and efficacy of this collaborative model.

"AN INCREDIBLE TOOL WITH MANY FLAWS." PRIMARY CARE PHYSICIANS' ATTITUDES TOWARD ELECTRONIC HEALTH RECORDS: AN INTERVIEW STUDY

Tania Moerenhout^{2, 2}; Gary Fischer¹; Marlies Saelaert²; An I. De Sutter²; Veerle Provoost²; Ignas Devisch². ¹University of Pittsburgh, Pittsburgh, PA; ²Ghent University, Ghent, Belgium. (Control ID #3175488)

BACKGROUND: The electronic health record (EHR) has evolved into a complex multifunctional tool that facilitates the sharing of medical information with both patients and their health care providers, even across institutions. Although much has been written about positive and negative effects of the EHR on efficiency, safety, and physician burn-out, many questions remain unanswered regarding the ethical dimensions of the EHR and its effect on the patient-doctor relationship. The aim of this study is to understand how general internists (PCPs) integrate the EHR into their workflow and what ethical questions arise while sharing medical information.

METHODS: The first author held semi-structured interviews between February and May 2017 with 14 PCPs recruited through a purposive, convenience-based sampling process from an academic general internal medicine practice of 46 faculty and 46 residents in Pittsburgh, PA. The clinic uses Epic software with a patient portal. Data were analyzed against a theoretical background of postphenomenology (combining the empirical orientation of Science and Technology Studies with a more conceptual philosophical analysis) and moral mediation (examining how "technologies mediate moral decisions and actions" (Verbeek. Moralizing Technology. Understanding And Designing The Morality Of Things.)), using thematic analysis in an iterative process. Three interviews were coded by 2 coders and discussed until consensus was reached. The first author continued the coding process with the established code book, expanding with new codes as needed. The thematic analysis process adhered to the six phases described by Braun and Clarke of data familiarization, code generation, theme identification, theme revision, theme definition and production of the final report.

RESULTS: Four major themes and 1 minor theme were identified. Major themes: (1) PCPs describe the EHR as a medicine with side effects, for which they provide suggestions for improvements; (2) The transition to a digitally shared record raises ethical dilemmas related to autonomy and paternalism; (3) Although use of the EHR often disturbs rapport with the patient, it can support patient-doctor communication when it becomes an active part of the conversation; (4) The digitalization of doctor-doctor communication has a complex effect on the concept of trust. Minor theme: A shared record may cause health care workers (and their relatives) to avoid seeking help for sensitive issues.

CONCLUSIONS: By understanding physicians' coping strategies and suggestions for improvement, and by focusing on the active integration of the EHR into patient-doctor communication, EHR design could be adapted to improve quality of care. EHRs raise underexplored issues of autonomy vs paternalism regarding sharing information with patients. More research is needed to understand the unexpected effects of the technology on moral dimensions of the patient-doctor interaction, in particular on autonomy and trust.

"I DIDN'T THINK IT WAS FAIR BECAUSE I'M NOT AN ABUSER": OPIOID TAPERING EXPERIENCES AMONG RACIAL AND ETHNIC MINORITIES IN A PRIMARY CARE SETTING

Hector R. Perez²; Ariana G. Pazmino²; Michele J. Buonora¹; Joanna L. Starrels². ¹Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY. (Control ID #3184347)

BACKGROUND: Substantial evidence exists that pain management practices differ by patient race and ethnicity, and that racial and ethnic minorities perceive their pain care as biased. However, prior studies have not examined the perspectives of racial and ethnic minorities on chronic opioid therapy (COT) about their experiences with opioid tapering.

METHODS: In this qualitative study, we conducted semi-structured 1:1 telephone interviews with patients who experienced opioid tapers in a primary care setting in a large urban health system in the Bronx, NY. Patients were eligible if they were at least 18 years old and were prescribed a stable dose of COT before undergoing a 30-100% dose reduction (opioid taper) between 2016 and 2017, as confirmed by manual chart review. Patients were ineligible if they had a history of cancer at the initiation of the taper or if they were not retained in care in the health system during the taper. Interview questions sought to understand patients' experiences and beliefs about opioid tapering, including perceived barriers and facilitators. Sociodemographics were collected by self-report and from the electronic medical record. Transcripts were coded and analyzed by two authors using a thematic analysis approach.

RESULTS: Of 43 patients contacted, 10 agreed to participate. Average age was 53.9, 5 were male, 6 were Black/African-American, and 4 were Hispanic. The overarching theme was participants felt unfairly targeted for a taper given their ongoing chronic pain; within this were three prominent sub-themes reflecting judgments derived from personal experiences. First, participants distinguished themselves from other patients who deceive providers to obtain opioids: "I know of a lot of people who only gets them to sell them, which makes it bad for people who really need it." Second, participants lacked trust in the healthcare system: "[The providers are] just telling me whatever to get a paycheck. They don't really care." Third, participants perceived themselves to have low risk for negative consequences of opioids: "If I'm in pain I'm going to take my medicine...I'm not that weak to sit there and...overdose." Key facilitators of successful tapering included support from friends, family, and providers: "[The taper] was a great experience...He's the best doctor I could ever ask for...He works for me...He's been with me the whole time."

CONCLUSIONS: In this sample of racial and ethnic minorities who experienced opioid tapers, we found that feeling unfairly targeted for a taper was a predominant theme. Participants described how their experiences with others who use opioids, with the healthcare system, and with their medications contributed to feelings of inequity. Future interventions for racial and ethnic minorities should address real and perceived inequities associated with tapering to promote patient engagement and facilitate successful tapering experiences.

"IF YOU CAN'T TALK TO YOUR DOCTOR ABOUT IT, WHO CAN YOU TELL?" A QUALITATIVE STUDY OF PATIENT ACCEPTABILITY AND PREFERENCES FOR SOCIAL RISK SCREENING IN HEALTH SETTINGS.

Elena Byhoff^{1, 2}; Emilia De Marchis³; Nancy E. Adler⁴; Kelly M. Doran⁵; Danielle Hessler³; Stephanie Ettinger de Cuba⁷; Eric Fleegler⁸; Nicholas Gavin⁹; Amy G. Huebschmann¹⁰; Stacy T. Lindau¹¹; Maria C. Raven¹²; Elizabeth L. Tung¹¹; Alicia Cohen⁶; Susan Jepson¹⁷; Wendy Johnson¹³; Cara C. Lewis¹⁶; Eduardo Ochoa¹⁴; Aric Prather³; Megan Sandel¹⁵; Richard Sheward¹⁵; Caroline Fichtenberg⁴; Laura M. Gottlieb⁴. ¹Tufts Medical Center, Boston, MA; ²Tufts University School of Medicine, Boston, MA; ³University of California, San Francisco, San Francisco, CA; ⁴UCSF, San Francisco, CA; ⁵NYU School of Medicine, New York, NY; ⁶Ann Arbor VA, Providence, RI; ⁷Boston University School of Medicine, Boston, MA; ⁸Boston Children's Hospital, Boston, MA; ⁹Columbia University Vagelos College of Physicians and Surgeons, Brooklyn, NY; ¹⁰University of Colorado School of Medicine, Aurora, CO;

¹¹University of Chicago, Chicago, IL; ¹²UCSF School of Medicine, Berkeley, CA; ¹³La Familia Medical Center, Santa Fe, NM; ¹⁴University of Arkansas for Medical Sciences, Little Rock, AR; ¹⁵Boston Medical Center, Burlington, VT; ¹⁶Kaiser Permanente, Seattle, WA; ¹⁷Hennepin Healthcare, Minneapolis, MN. (Control ID #3180063)

BACKGROUND: As research supporting potential benefits of social risk screening in health settings continues to emerge, there is little data on the patient perspective on social screening. The aim of this study is to describe the perspectives and preferences of patients and caregivers on being screened for social risks in diverse health care settings.

METHODS: As part of a larger mixed methods multi-site study, we conducted semi-structured interviews lasting approximately 30 minutes with patients or caregivers who had completed the Center for Medicare and Medicaid Innovation (CMMI) social risk screening tool. After completion of the screening questions, 5 randomly selected respondents from each of 10 study sites were invited to participate in an interview. Interviews were conducted in English or Spanish. The interview guide asked about reactions to social risk screening and screening acceptability, preferences on screening administration, prior experiences that informed perspectives, and expectations for social assistance. Interviews were recorded, transcribed and translated. Two coders used basic thematic analysis and constant comparative methods to identify codes, group codes into unified themes and map themes into domains of screening acceptability.

RESULTS: Fifty adult patients or caregivers participated in semi-structured interviews across all study sites, which included 6 primary care clinics and 4 emergency departments. Respondents were 78% female, 36% Black, 32% Hispanic, 20% caregivers, and 71% reported having one or more social risk factor. There was broad consensus among interviewees across all clinical sites that social risk screening was acceptable. Several themes emerged: (1) respondents felt screening was the "right thing to do;" (2) respondents identified framing and compassionate approach as the most important aspects of administration; (3) respondents had insight into the connections between social risks and physical and mental health. Despite overall agreement that social risk screening is appropriate, respondents did not expect their health care team to address or resolve all of the identified issues. Interviewees felt referrals out to social services and resource sheets were adequate, and that there was benefit to the act of screening itself. Patients emphasized that screening should be done with empathy while protecting patient confidentiality.

CONCLUSIONS: Respondents agree that social risk screening is important, acceptable, and relevant to health. Respondents believed social risk screening would be most acceptable when implemented by a clinic staff member trained to ensure privacy and compassion. Despite published concerns about futility of social risk screening when social resources are inadequate, respondents expressed that they did not expect the health care system, and physicians in particular, to solve unmet social problems. Done appropriately, screening for social risk can build trust and strengthen relationships between patients and health care providers.

"LAUGH AND BACK OUT OF THE ROOM:" FEMALE PHYSICIAN STRATEGIES FOR DEALING WITH SEXUAL HARASSMENT BY PATIENTS

Amy H. Farkas^{2, 1}; Cecilia Scholoff^{2, 1}; Cynthia Kay^{1, 2}; Julie Lucas^{2, 1}; Sarah Nickoloff^{2, 1}; Kathlyn Fletcher^{2, 1}; Jeffrey L. Jackson^{1, 2}. ¹Zablocki VAMC, Milwaukee, WI; ²Medical College of Wisconsin, Milwaukee, WI. (Control ID #3183047)

BACKGROUND: Sexual harassment of providers by patients has not received as much attention as harassment from other sources. Our purpose was to assess the types of harassment encountered, level of discomfort and strategies used by providers to deal with patient sexual harassment.

METHODS: We used a mixed-method approach combining a survey and qualitative, semi-structured interviews at a Midwestern academic medical center and affiliated VA. The survey assessed provider characteristics, forms of sexual harassment experienced as well as a Likert-scaled assessment of the degree the behavior was bothersome. Semi-structured interviews assessed provider experience with sexual harassment, how they dealt with it, whether they reported it, and strategies they used to mitigate harassment. We used purposive sampling, grounded theory and duplicate coding to generate themes.

RESULTS: The average participant was 43 years old and graduated medical school 17 years ago (range 2-45). Some forms of verbal harassment were nearly universal (being mistaken for a nurse, remarks on appearance, questions about marital status, sexist jokes). Physical harassment was less common (90% had experienced leering and standing too close, 44% had experienced suggestive exposure of patient's body). The commonly experienced forms of harassment were mostly rated as "bothered a little," while physical forms of harassment were nearly universally rated as "extremely bothersome." During interviews, respondents described predisposing factors that made harassment more likely, such as patient factors (cognitive impairment, older age), provider factors (experience), and cultural factors. Harassment took many forms and occurred across a spectrum, from compliments/comments about appearance to addressing questions to the males in the room rather than the female attending physicians, to sexual propositions or actual grabbing. These episodes impacted not only the targeted women, but also other patients who witnessed the events, other staff, and learners. The respondents identified several strategies for dealing with patient-initiated sexual harassment. These strategies included preventing it (modifying dress, having only male providers for certain patients), terminating it (using humor, redirecting the patient) and coping with it (debriefing with colleagues). Respondents often used nonconfrontational methods for diffusing situations, but later regretted not being more direct.

CONCLUSIONS: Some forms of verbal sexual harassment by patients are nearly universal, though are experienced as minimally bothersome. More serious forms of harassment are less common, and respondents rated these as extremely bothersome. Participants identified a number of factors that increase the likelihood of experiencing harassment as well as strategies for mitigating and managing it

"MAY I PLEASE SEE YOUR INSURANCE CARD AND ID?": HOW PATIENTS WITH LIMITED-ENGLISH PROFICIENCY COMMUNICATE WITH ANCILLARY STAFF DURING THE PRIMARY CARE VISIT

Lily Kornbluth¹; Celia P. Kaplan²; Leah S. Karliner¹. ¹UCSF, San Francisco, CA; ²University of California San Francisco, San Francisco, CA. (Control ID #3165795)

BACKGROUND: Limited English Proficiency (LEP) is associated with health disparities which can be ameliorated with use of professional interpretation. Numerous studies have investigated communication between clinicians and patients with LEP. However, little is known about communication between ancillary staff and patients with LEP. This study describes communication patterns between front desk staff and medical assistants (MAs) and patients with LEP in an academic primary care setting.

METHODS: This descriptive study is part of the Language Access Systems Intervention (LASI) study on communication for patients with LEP conducted at a large, urban, academic primary care practice. In the LASI study, 735 patients with LEP (Spanish, Cantonese, and Mandarin-speaking) completed a telephone survey

that included questions about language barriers with front desk staff and MAs. Following analysis of these survey data, we conducted semi-structured interviews with 6 front desk staff, 6 MAs, and 3 physicians in the practice to lend qualitative perspective to the patient survey results. Detailed notes were taken during the semi-structured interviews with subsequent thematic analysis.

RESULTS: Among the 735 participants with LEP surveyed, half (49%) reported speaking in their preferred non-English language directly with bilingual front desk staff, and 38% directly with MAs. However, one-third (30% with front desk, 32% with MAs) used English to communicate. Among those using English, 76% rated their ability to speak English as 'not well' or 'not at all'. Professional interpreter use was minimal (3%) with ancillary staff overall. Communication patterns varied by language, with Spanish-speakers using English more frequently than other Chinese-speakers (51% vs 25% of Cantonese and Mandarin-speakers). In semi-structured interviews, front desk staff and MA's reported that often patients' limited English was sufficient for basic tasks, although they acknowledged that more complex tasks required professional interpretation (e.g. medication review). However, they rarely accessed professional interpretation due to perceived time constraints. Physicians commented that they took on extra tasks during visits for patients with LEP, such as medication reconciliation, because ancillary staff were not using interpreters and then not completing the tasks they normally would with English-speakers.

CONCLUSIONS: Our results highlight a previously undocumented communication challenge in ambulatory care: minimal professional interpreter use by front desk staff and MAs leading to many patients with LEP getting by with very limited ability to communicate in English. As a result, physicians feel the burden of extra tasks during already complex visits. Suboptimal communication with ancillary staff makes true team-based care challenging, and must be addressed in order to provide high quality, equitable care for LEP populations.

"SO I DO HAVE A COCKTAIL. IT'S VERY POPULAR": NON-OPIOID MEDICATION AND SUPPLEMENT MISUSE AMONG OPIOID USERS EXPERIENCING HOMELESSNESS

Avik Chatterjee^{4, 1}; Shankar Ramkellawan²; Diego B. Lopez³; Jessie M. Gaeta⁴; Kamala Smith⁴; Travis P. Baggett^{5, 4}. ¹Harvard Medical School, Cambridge, MA; ²Harvard College, Boston, MA; ³Harvard Medical School, Boston, MA; ⁴Boston Health Care for the Homeless Program, Boston, MA; ⁵Massachusetts General Hospital, Boston, MA. (Control ID #3175784)

BACKGROUND: While the impact of the opioid epidemic in the United States continues, certain aspects of the epidemic have changed, requiring updates in clinical practice. Recent evidence suggests that the practice of combining opioid use with non-opioid medications to alter the opioid high is common, though little is known about this phenomenon and how best to address it.

METHODS: We recruited adults who reported current opioid use from a low-threshold engagement center targeting individuals experiencing homelessness in Boston, Massachusetts. We conducted semi-structured interviews to explore the practice of combining non-opioid medications and other substances with opioids. We used Borkin's immersion/crystallization approach to analyze transcripts to uncover themes.

RESULTS: Twenty-two individuals completed interviews. Mean age of participants was 36.3 years, and 36% (8/22) reported female gender. Fifty-nine percent (13/22) reported White race, 36% (8/22) reported Black race, and 64% (14/22) reported Latino ethnicity. Combining substances with opioids to alter the high was a common

practice: "So I do have a cocktail. It's very popular." Participants reported use of clonidine, gabapentin, benzodiazepines, Phenergan, Adderall, Seroquel, barbiturates, Nyquil, Robitussin, and Tylenol PM as well as alcohol and candy. Participants most commonly reported purchasing these substances on the street, but less commonly reported stealing them or getting them from a doctor. Participants identified several purposes of combining substances: to augment the high ("I heard [gabapentin] gets you a higher high like really hits you so I wanted to get that"), to alter the high ("Never done mushrooms but [Robitussin is] similar to that"), or to offset the opioid high ("So, you know, the sugar [from candy] would lift up the high"). Importantly, participants also reported combining substances to treat psychiatric symptoms: "I use drugs to self-medicate. If I [feel] depressed." Individuals commonly reported learning about combining substances "from people on the street" but also reported learning from the internet and television: "Ah, from TV. [Nyquil] is supposed to make you sleepy so I thought it would give the same effect with the opioid." Safety was either not a concern or was outweighed by perceived benefits: "When I'm doing it I don't care about safety. I be wanting to feel nothing." Participants also felt that combining over-the-counter or prescription medications would be safe: "Not think about [safety] cuz it's not that strong like the pills. It's just for sleep."

CONCLUSIONS: Combining a wide variety of substances with opioids is common, and driven by a diverse range of motives. Clinicians who care for opioid-involved patients should consider screening for concurrent use of other substances and discussing the potential risks of this practice. Adequately diagnosing and treating psychiatric conditions may also decrease risky combinations of substances with opioids.

#METOO: A NATIONAL STUDY OF FORCED SEXUAL INITIATION AMONG US WOMEN

Laura Hawks^{1, 4}; Stephanie Woolhandler²; David Himmelstein³; David Bor¹; Adam Gaffney¹; Danny McCormick⁴. ¹Cambridge Health Alliance, Cambridge, MA; ²Cambridge Hospital, New York, NY; ³City University of New York at Hunter College, New York, NY; ⁴Harvard Medical School / Cambridge Health Alliance, Cambridge, MA. (Control ID #3185066)

BACKGROUND: The #MeToo movement has highlighted the frequency of sexual assault. However, no previous studies have assessed the incidence of sexual assault during women's first sexual encounter, or its reproductive and general health sequelae.

METHODS: We analyzed data on female respondents to the 2011-2017 National Survey of Family Growth, a nationally-representative, in-person survey conducted by the CDC. We excluded women with no history of vaginal intercourse. Using survey weights provided by the CDC, we assessed the number and characteristics of women who experienced forced sexual initiation (FSI), and the age of the male partner. We also examined the association between FSI and subsequent reproductive outcomes, gynecologic illnesses and other health measures. We used linear regression to assess continuous outcomes and logistic regression for binary outcomes. Models controlled for women's age, poverty status, race, current employment and place of birth; for reproductive outcomes we also adjusted for marital status and education.

RESULTS: Among women age 18-44 at the time of the survey 6.5% (n=993, representing 3,351,733 nationally) reported FSI. The mean age at first intercourse for those experiencing FSI was 1.3 years younger than for other women, 16.6 years [95% CI 15.8-17.4] vs. 17.9 [17.7-18.1]. The age discrepancy of first male partners was much larger, 27.0 [24.8-29.2] vs. 21.0 [20.6-21.3] years. 29.0% of women with FSI (vs. 12.2% without FSI) reported

sexual initiation before age 15 and 6.0% of women with FSI (vs. 0.1% without FSI) reported sexual initiation before turning 11. Women who experienced FSI were somewhat less likely to be white, born in the US, college educated and have incomes above the poverty level, but all demographic groups reported substantial rates. Women who reported FSI had more lifetime pregnancies (2.4 vs. 1.9 p<0.001) and lifetime sexual partners (9.6 vs. 7.4 p<0.001), and were more likely to have an unwanted first pregnancy (OR 1.7 [1.3-2.2]) and an abortion (OR 1.4 [1.1-1.8]). FSI survivors had higher rates of gynecologic illnesses, e.g. endometriosis (OR 1.6 [1.1-2.3]), pelvic inflammatory disease (OR 2.2 [1.5-3.4]) and disorders of ovulation or menstruation (OR 1.8 [1.4-2.3]) than other women. Though uncommon in both groups, victims of FSI more frequently reported illicit drug use (2.6% vs. 0.7%, OR 3.6 [1.8-7.0]) in addition to fair or poor health (OR 2.0 [1.5-2.7]) and difficulty completing tasks due to a physical or mental health condition (OR 2.8 [2.0-3.9]).

CONCLUSIONS: Violent sexual initiation is common, and associated with adverse reproductive and general health outcomes, and may impact functioning later in life. These findings highlight the importance of trauma-informed care in clinical settings, and the urgent need to develop public health and other strategies to prevent sexual coercion and assault.

BUPRENORPHINE AND THE TREATMENT DIVIDE BETWEEN WHITES AND BLACKS

Pooja A. Lagisetty; Ryan Ross; Amy Bohnert; Michael Clay; Donovan Maust. University of Michigan, Ann Arbor, MI. (Control ID #3184065)

BACKGROUND: Opioid overdoses are increasing amongst both Black and White populations, but receipt of medication treatment for opioid use disorders (OUD) may differ by race and income. Studies examining disparities in receipt of medications used to treat OUD have been limited to examining methadone and buprenorphine provided by opioid treatment programs (OTPs). However, most patients never seek specialty addiction treatment and are largely cared for in office-based settings. There have been no studies examining racial disparities in the receipt of buprenorphine in office-based settings, where the majority of patients seek care. Here we describe time trends in buprenorphine office-based visits by race and payment type in the US.

METHODS: We combined data from the National Ambulatory Medical Care Survey (NAMCS) and the National Hospital Ambulatory Medical Care Survey (NHAMCS) hospital outpatient departments (OPD) to examine visits where buprenorphine was prescribed between 2004-2015, aggregated into four-year periods. We estimated buprenorphine prescription rate estimates by race and payment. We used the most recent period (2012-2015) to test the association of race with receipt of buprenorphine with logistic regression adjusting for age, gender, payment method, and complex survey design elements.

RESULTS: Between 2004-2015, buprenorphine visits rose from 0.04% of all ambulatory visits to 0.36% and in total constituted an estimated 13.4 million visits between 2012-2015. By 2012-2015, buprenorphine was a prescribed medication during more visits of white patients than other races (12.7 million [CI 8.6 million - 16.8 million] versus 363,000 [CI 134,000 - 594,000]). Self-pay and private insurance were the most common payment methods across all years. The use of self-pay for buprenorphine visits dramatically increased from 585,568 [CI 0 - 1.3 million] visits in years 2004-2007 to 5.3 million [CI 2.5 million - 8.5 million] in 2012-2015. After accounting for payment, gender, and age, Black patients had significantly lower odds of receiving buprenorphine at their visits (adjusted odds ratio 0.23 [CI, 0.13-0.44].

CONCLUSIONS: Our findings demonstrate wide and growing disparities in the receipt of buprenorphine by race and insurance across the U.S. It is notable that, nationally, visits paid for by private insurance and self-pay have surpassed those paid for with public insurance despite recent improvements in addiction treatment coverage for Medicaid beneficiaries after the Affordable Care Act. This study provides alarming evidence of disparities in buprenorphine treatment for OUD. With rising rates of opioid overdoses, it is imperative that policy and research efforts specifically address racial and economic disparities in treatment access and engagement.

INCREASING THE MEDICAL PIPELINE: ANALYSIS OF A SUMMER EDUCATION PROGRAM FOR PHILADELPHIA HIGH SCHOOL STUDENTS

Krystal Hill; Catherine Raney; Heardley M. Murdock; Jaya Aysola. University of Pennsylvania, Philadelphia, PA. (Control ID #3185558)

BACKGROUND: Mounting evidence reveals the benefits of diversifying our physician workforce, yet many minority and low socio-economic populations remain underrepresented. In response, many academic medical centers have pipeline programs designed to provide educational opportunities to underrepresented populations. Yet, little is known about their effectiveness. Thus, we evaluated a well-established pipeline program to identify what student and program factors yield optimal benefit.

METHODS: We analyzed the impact of The Summer Mentorship Program-Medicine (SMPM), a high school medical education pipeline program at the University of Pennsylvania (n=12 students) with the Kirkpatrick model, an established method to evaluate educational programs. We surveyed students to assess overall program satisfaction and the perceptions of learning across the following domains: academic enhancement, career discussion with medical students and physicians, health science lessons, patient care and procedures, mentorship and field experiences, and public health with community-based problem solving. We examined the relationship between student demographics, academic characteristics, and student success defined by the following three outcomes: 1) program satisfaction 2) pre-post SAT scores and 3) 4-month follow-up self-reported SAT scores. We examined student demographic and academic factors such as race/ethnicity, sex, socioeconomic status, single parent home, college readiness index (rating of a high school's college preparatory curriculum), parental education, siblings in college, pipeline program rankings to gauge interest in medicine, grade point average (GPA), recommendation letters, and personal essays.

RESULTS: All students (n=12) were from low-income households and 10 of 12 would be the first in their families to attend college. A third were males and 25% had GPAs < 3.00. Students rating for overall program was 4.2 out of 5. Program domains with the highest rankings included health science lessons (4.48), patient care and procedures (4.48), and mentorship and field experiences (4.55) (p<0.05). Interquartile ranges for pre, post, and follow-up SAT scores were 613-788, 769-863, and 1000-1150, respectively (p< 0.05). Significant predictors of higher follow-up SAT scores were the "college readiness index" and "ranked medicine first" (p=0.05). Notably, there was no statistically significant relationship between GPA and outcomes.

CONCLUSIONS: This study of a well-run, well-funded high school pipeline program reveals that hands-on activities such as patient care and procedures provide high program satisfaction and perceptions of learning. Our results suggest that students benefit from intensive standardized test preparation and that those with lower academic scores may derive equal benefit from and succeed in pipeline programs. Lastly, we found that holistic factors such as interest or motivation may better predict success in pipeline programs over traditional factors, such as GPA.

INTEGRATING GERIATRICS INTO INTERNAL MEDICINE CORE CURRICULUM: AGING THEME

Alyson Michener; Jerry Johnson; Rachel K. Miller. University of Pennsylvania, Philadelphia, PA. (Control ID #3185706)

BACKGROUND: In 2014, our internal medicine (IM) residency program moved to a "6+2" block schedule and theme-based ambulatory curriculum. Geriatrics/Aging was designated a longitudinal theme to span all three years. We created an aging curriculum for IM residents that increased exposure to geriatric competencies and enhanced training in the care of older adults.

METHODS: We integrated an aging theme into the IM categorical and primary care outpatient curricula. In each year of training, we co-taught several didactics with other specialists to promote collaboration and sharpen the relevance of each topic. Those topics included PGY1 (categorical and primary care): Geriatric Assessment 1 (fall) & 2 (spring) and capstone of spring Renal block (co-taught with renal), Hypertension guidelines for Older Adults (incorporating multi-morbidity). We reinforced that knowledge in the (mandatory) PGY2 ACE unit rotation and PGY3 geriatric community-based, service-learning experience. PGY2/3 (categorical) topics included: Geriatric Polypharmacy (co-taught with pharmacist), Hot Topics in Dementia, Shared Decision Making in Cancer Screening for Older Adults (co-taught with oncology) and Healthy Aging. Each talk was given 4 times to reach all learners. Additionally, the primary care residents had 5 geriatrics didactics per year, as above, and toured local senior sites. Before and after implementing the curriculum, we compared annual ACGME evaluation responses regarding the adequacy of geriatric training. We also evaluated resident performance on geriatric questions on the annual in-training exam.

RESULTS: The ACGME evaluations showed a significant increase in residents who assessed themselves as possessing adequate experience in geriatrics (71% prior to implementation in 2013-14 year versus 87.5% in the 2016-17 academic year). In 2017, the residents mean percent correct score was 77% (62 residents) of the geriatrics questions on the in-training exam - a 6% increase from 2014. We also observed more residents choosing longitudinal rotations in geriatrics and geriatrics fellowships. On the in-training exam in 2014, residents mean percent correct scores in geriatric medicine was 70% compared to 77% correct in 2017.

CONCLUSIONS: An Aging curriculum is now standard in our IM curriculum. Given that other internal medicine programs have similar block schedules, this curriculum could be replicated and adapted. We will continue expanding the aging theme and evaluating the IM residents' care of older adults.

LIFESTYLE INTERVENTION PROGRAMS FOR ADULTS AT HIGH-RISK FOR TYPE 2 DIABETES: A PLATFORM TO REACH HIGH-RISK CHILDREN?

Maya S. Venkataramani¹; Tina L. Cheng²; Nisa Maruthur¹. ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Johns Hopkins, Baltimore, MD. (Control ID #3175404)

BACKGROUND: Type 2 diabetes risk factors cluster in families, and family-oriented approaches to identify high-risk individuals and prevent disease can have a multi-generational public health impact. The National Diabetes Prevention Program (DPP) lifestyle intervention targets high-risk adults who meet body mass index (BMI) and other eligibility criteria. Eligible adults may have family members, including children, who are also at high-risk for type 2 diabetes. As such, the National DPP could provide a unique platform through which to identify, and intervene upon, diabetes risk across generations. To understand the potential multi-generational reach of family-oriented approaches to identifying and intervening upon high-risk

adults and children, we explored the correlation between parental eligibility for the National DPP program and child weight status using nationally representative data.

METHODS: We analyzed nationally representative data from the National Health Interview Survey from 2016 and 2017, focusing upon sample children ages 12 through 17 years old for whom BMI data was available and who could be linked to a parent (selected as a sample adult in the survey). Child BMI was categorized as underweight/normoweight, overweight or obese, using CDC BMI-for-age criteria. Parental DPP eligibility was determined based upon National DPP eligibility criteria (being overweight/obese; and a self-reported diagnosis of prediabetes or gestational diabetes history). Using Pearson's chi-squared analyses, we explored the association between 1) parent and child BMI and 2) parental DPP eligibility and child BMI.

RESULTS: Our analytic sample consisted of 13,633,334 weighted (3905 unweighted) children, each linked to one parent. 50.1% of children and 61.6% of parents were females. 25.9% of children and 68.1% of parents were overweight or obese. Child and parent BMI were correlated (Chi-squared p <0.001): over one-fifth of obese parents had at least one obese child compared to only 5% of underweight/normoweight parents. 9.5% of parents were likely eligible to participate in the National DPP. Parental DPP eligibility was positively correlated with child overweight/obese status (Chi-squared p <0.001): nearly 1 in 5 (19.8%) of likely eligible parents had a child who was obese, compared to 11.0% of ineligible parents. Overall, more than one-third of likely eligible parents in the sample had at least one child who was overweight or obese.

CONCLUSIONS: In this nationally representative sample, parent and child BMI were positively correlated, as was parental eligibility for diabetes prevention programming and child BMI. This highlights the potential of leveraging the national platform for adult diabetes prevention to identify and reach high-risk children through family-oriented, multi-generational programming. Limitations include the use of self-reported weight and height (potentially leading to misclassification at extremes of BMI), and confirming these associations with measured BMI is an important next step.

MAJOR CAUSES OF DEATH AMONG TRIBAL COMMUNITIES IN SOUTH DAKOTA

Stephanie Sun; Leila H. Borowsky; Matthew Tobey. Massachusetts General Hospital, Boston, MA. (Control ID #3186016)

BACKGROUND: In the Great Plains (ND, SD, NB, and IA), the American Indian/Alaska Native (AI/AN) life expectancy is 10 years less than the US total population. The health disparities facing AI/AN populations have been attributed to systemic discrimination, poverty, and remoteness, among other factors. Over the past 60 years, health disparities between AI/AN and white populations have decreased everywhere except the Great Plains, where they have increased. Efforts by tribal leaders, policymakers, and healthcare experts to address AI/AN health relies on data that reflects the needs of their tribal communities. Studies that have reported state and regional data may miss nuances between reservations. We collected mortality data of individual reservations in South Dakota (SD). By focusing on local data, we found both areas of similarity and uniqueness across SD reservation health profiles.

METHODS: We used CDC Wonder data to collect the top 15 leading causes of death from 1999-2017 by county for all 10 SD reservations. Crude death rates per 100,000 and number of deaths were obtained and compared to that of SD and the US. All ages, genders, and races were included. Crude death rates for all reservations were averaged and compared to the top 15 leading causes of death for SD, and for the USA.

RESULTS: Generally, the mortality rate of SD reservations was higher than the total state, which was higher than that of USA. Notable exceptions include Alzheimer's disease, where the mortality rate of SD reservations equalled that of all of SD, which in turn was greater than that of USA. The top two causes of death on South Dakota reservations are diseases of the heart and malignant neoplasms, with crude death rates of 245 and 211, respectively. This was similar to the top two causes of death in SD and USA. Unintentional accidents, intentional self-harm (suicide), and chronic liver disease were ranked higher in SD reservations. Nephritis, nephrotic syndrome and nephrosis, septicemia and Parkinson's disease were ranked higher in USA and SD. Mortality data of reservations varied widely. Two reservations, Lower Brule and Ponca, consistently had the lowest crude death rates of all SD reservations. Three reservations, Pine Ridge, Rosebud, and Yankton, consistently had the highest crude death rates of all SD reservations. Pine Ridge and Rosebud, two neighbouring reservations, were the sole reservations with assault (homicide) as a leading cause of death.

CONCLUSIONS: These findings point to common ground where national and state-wide efforts can be focused. This data also demonstrates the unique needs of different communities. A deeper look at the reservation-level data demonstrated heterogeneity amongst health profiles of different reservations, highlighting the importance of targeted interventions tailored to each reservation's needs. Future studies will examine the factors influencing these differences, and will examine the trends in mortality data over time for each reservation.

THE POTENTIAL IMPACT OF UNIVERSAL MEDICAID EXPANSION ON ECONOMIC AND RACIAL DISPARITIES IN COVERAGE

Elisabeth Poorman¹; Hugo Torres²; Danny McCormick³. ¹Cambridge Health Alliance, Cambridge, MA; ²Cambridge Health Alliance, Somerville, MA; ³Harvard Medical School / Cambridge Health Alliance, Cambridge, MA. (Control ID #3185857)

BACKGROUND: While the Affordable Care Act (ACA) narrowed racial and socioeconomic disparities in coverage, uninsurance remains substantial in these groups. Currently, 14 states have not expanded Medicaid. Little is known about the number of racial/ethnic minorities or low-income adults that would gain coverage under universal Medicaid expansion.

METHODS: We analyzed BRFSS, a nationally representative telephone survey, for adults 18-64 in the 2 years prior to (2012-2013) and the 2 years following (2015 and 2016) ACA implementation. We calculated the pre-to post ACA percentage point difference in coverage gains between Medicaid expansion (MES) and non-expansion (NES) states. Using logistic regression and predictive margins, we adjusted for age, sex, education, marital and employment status and 3 state-level factors: 1) the use of a state vs federal insurance exchange; 2) state per capita federal funding for insurance enrollment support; and 3) the pre-ACA percentage of the state that was Medicaid eligible. We multiplied the adjusted difference by the population of the NES and applied weights provided by the BRFSS to project number of newly insured total, black, Hispanic, low-income adults and chronic disease patients if all states expanded Medicaid.

RESULTS: Unadjusted coverage gain were 2.3 percentage points higher in MES following the ACA (1.7, 3.0). The adjusted difference was 1.8 percentage points (1.3, 2.4), representing a projected gain in coverage for 1,354,514 Americans. For those with a chronic disease, there was an adjusted 2 percent greater increase in coverage in MES, representing a projected gain in coverage for 614,798 people. There was a 2 percent (1.2, 2.9)

increase for Blacks in MES (241,573). Hispanics experienced a 5.2 percentage point (4.3, 6.2) gain in MES (698,510). For low income adults, the adjusted difference in coverage was 4.7% (3.7, 5.7) (1,178,960).

CONCLUSIONS: More than a million Americans stand to gain insurance coverage if all states expanded Medicaid. Most gains would be among low-income adults, and racial minorities and thus would likely further reduce existing wide disparities in coverage for these groups.

THE WELL-BEING OF SWISS GENERAL INTERNAL MEDICINE RESIDENTS

Brigitta I. Zumbrunn¹; Odile Stalder²; Andreas Limacher²; Maxime Schmutz¹; Peter E. Ballmer³; Stefano Bassetti⁴; Edouard Battegay⁵; Juerg H. Beer⁶; Michael Brändle⁷; Daniel Genné⁸; Daniel Hayoz⁹; Christoph Henzen¹⁰; Lars C. Huber¹¹; Pierre-Auguste Petignat¹²; Jean-Luc Reny¹³; Peter Vollenweider¹⁴; Drahomir Aujesky¹. ¹Bern University Hospital, Bern, Switzerland; ²University of Bern, Bern, Switzerland; ³Kantonsspital Winterthur, Winterthur, Switzerland; ⁴University Hospital of Basel, Basel, Switzerland; ⁵University Hospital Zurich, Zurich, Switzerland; ⁶Cantonal Hospital of Baden, Baden, Switzerland; ⁷Cantonal Hospital of St. Gallen, St. Gallen, Switzerland; ⁸Cantonal Hospital of Biel, Biel, Switzerland; ⁹HFR Hopital Cantonal, Fribourg, Switzerland; ¹⁰Cantonal Hospital of Lucerne, Lucerne, Switzerland; ¹¹City Hospital Triemli Zurich, Zurich, Switzerland; ¹²Hospital of Valais, Sion, Switzerland; ¹³Geneva University Hospitals, Geneva, Switzerland; ¹⁴Lausanne University Hospital, Lausanne, Switzerland. (Control ID #3184797)

BACKGROUND: Physician well-being is not only associated with empathy and professionalism, it has also a direct impact on productivity, quality of care, and patient safety. Residency training is a challenging and particularly stressful period in the life of physicians. We therefore assessed the well-being of Swiss general internal medicine (GIM) residents as well as associated personal and work-related factors.

METHODS: We conducted an anonymous electronic survey among GIM residents from 13 Swiss teaching hospitals in June 2018. Participants were asked to indicate personal and work-related characteristics and to complete the Physician Well-Being Index (PWBI), which measures 6 domains (burnout, depression, stress, fatigue, and mental and physical quality of life). We explored the association between a reduced well-being (PWBI 5 points) and personal and work-related factors using multivariable mixed logistic regression. We used spearman's rank correlation coefficient to examine the relationship between the PWBI and job satisfaction, self-reported medical errors, suicidal ideation, and intention to leave clinical practice.

RESULTS: The response rate was 54% (472/880). Although 95% of residents were at least partially satisfied with training quality and 91% with their job autonomy and the job overall, 19% of participants had a reduced well-being, 60% felt burned out, 57% reported emotional problems, and 21% had career choice regret. Age (OR 1.20, 95% CI 1.06-1.35), having children (OR 0.10, 95% CI 0.02-0.41), <2.5 personally rewarding work hours per day (OR 3.01, 95% CI 1.62-5.61), low satisfaction with training quality (OR 2.40, 95% CI 1.34-4.31), and low satisfaction with job autonomy (OR 2.42, 95% CI 1.36-4.28) were significantly associated with reduced well-being, but not working hours, administrative workload, and satisfaction with income. We found significant, weak to moderate correlations between the PWBI and job satisfaction ($r_s=0.54$, $p<0.001$), medical errors ($r_s=0.18$, $p<0.001$), suicidal ideation ($r_s=0.12$, $p=0.009$), and the intention to leave clinical practice ($r_s=0.38$, $p<0.001$).

CONCLUSIONS: Our survey reveals a mixed picture. Although the vast majority of Swiss GIM residents are satisfied with many aspects of their job, approximately 20% appear to have a reduced well-being or career choice regret and around 60% feel burned out or report emotional problems. Having few rewarding work hours and a low satisfaction with training quality and job autonomy are the most significant predictors of reduced well-being. Given the human costs of physician distress to both patients and physicians, health care organizations have the shared ethical and professional responsibility to improve physician well-being, for instance by providing adequate support structures and staffing levels.

1-ITEM BURNOUT MEASURE CORRELATES WELL WITH EMOTIONAL EXHAUSTION DOMAIN OF BURNOUT BUT NOT DEPERSONALIZATION

Tabor E. Flickinger; Rachel H. Kon; Rebecca Jacobsen; Justine E. Owens; John Schorling; Margaret L. Plews-Ogan. University of Virginia, Charlottesville, VA. (Control ID #3171873)

BACKGROUND: Burnout is a serious concern in medical education and practice with negative impact on trainees' professionalism and patient care. Accurate measurement of burnout is necessary for medical education scholarship and intervention evaluation. The Maslach Burnout Inventory (MBI) is a validated 22-item tool with three domains of emotional exhaustion (EE), depersonalization (DP), and personal accomplishment (PA). A 1-item burnout measure is faster and easier to administer than the full MBI and is available at no cost. However the correlation between a 1-item measure and the full MBI has not been established for physicians-in-training. We aimed to compare measurement of burnout by these two tools among medical students.

METHODS: All medical students at our academic medical center receive an online survey annually. Since 2014, this survey has included the full MBI to measure burnout. In the 2017-2018 academic year, we added the 1-item burnout measure, previously used in the Physician Work Life Study (PWLS). This item asks respondents to rate their level of burnout with responses from 1 (no burnout) to 5 (severe burnout). Previously established cut-offs for high scores were used for both measures. Scores on the 1-item PLWS burnout measure and the full MBI domains of EE and DP were compared using Pearson correlation and Chi square tests.

RESULTS: Of the 631 surveys sent, 287 students completed the 1-item PWLS burnout question and the full MBI (46% response rate). Mean scores on EE were 21.6 (SD 10.8) and on DP 6.4 (SD 5.4). Mean score on the 1-item PLWS measure was 2.17 (SD 0.726). Scores on EE and DP domains were moderately correlated with each other ($r=0.472$, $p<0.001$). Scores on the 1-item PWLS measure showed strong correlation with EE scores ($r=0.665$, $p<0.001$) but weak correlation with DP scores ($r=0.160$, $p=0.007$). High burnout was reported by 34% of students for EE (scores above 27) and 25% for DP (above 10). On the 1-item PWLS measure, 21.3% of students reported high burnout (3 and above). Students with high scores on the 1-item PLWS measure were more likely to have high EE than low/medium EE (86% vs 19%, $p<0.001$) but no significant difference on high vs low/medium DP (31% vs 24%, $p=0.248$).

CONCLUSIONS: The 1-item PWLS measure correlated better with EE than with DP domains of burnout. When asked by the 1-item measure to rate their own level of burnout, respondents may primarily express how drained or fatigued they feel, which corresponds well to EE. However, DP appears to measure a different concept which captures the ability to treat patients with empathy. DP is a particularly worrisome aspect of burnout because it may undermine the formation of therapeutic relationships with patients and how well future physicians deliver patient-centered care. DP may not be well evaluated by the 1-item

PWLS burnout measure, as compared to the full MBI, and should be used and interpreted with caution by medical educators and researchers.

12MONTH OUTCOMES: UTILIZING REMOTE GLUCOSE MONITORING TO DELIVER CONTINUOUS, PATIENT-CENTERED CARE AND IMPROVED OUTCOMES

Elizabeth B. Kirkland¹; Jingwen Zhang¹; Justin Marsden²; William P. Moran². ¹MUSC, Charleston, SC; ²Medical University of South Carolina, Charleston, SC. (Control ID #3186342)

BACKGROUND: Remote patient monitoring (RPM) is an accessible tool for chronic disease management. This technology improves access to care and provides up-to-date data for provider action. While there is a growing body of evidence to suggest that diabetic and hypertension control improves at 6months with home monitoring, there is less evidence for effectiveness or sustained improvement at 12months follow up time. Meta-analyses of remote interventions for other chronic diseases, such as obesity, reveal promising improvement up to 6months, but insignificant change at 12months. We seek to determine whether remote patient monitoring of glucose over 12months, with provider engagement to allow for medication changes in the inter-visit period, will produce sustained improvements in hemoglobin A1c (hbA1c) at 12 months or longer.

METHODS: Over 600 patients across the state of South Carolina enrolled in a remote monitoring program utilizing an easy-to-use, 2-in-1 automated device with blood pressure and glucose monitoring capability. The device transmits data directly to a secure database through SIM technology for healthcare provider review, obviating the need for Bluetooth, cords, or other ancillary devices. Patients were eligible for participation if they had an hbA1c of 8 or higher within 21 days of enrollment. Providers were encouraged to view these incoming data and to make adjustments to diabetes and/or hypertension treatment plans at their discretion. HbA1c measurements were obtained at baseline, 6-, and 12-months after enrollment and compared via paired t-tests (baseline to 6mo, 6mo to 12mo, and baseline to 12mo).

RESULTS: We report on the changes in hbA1c as a marker of diabetes control over time. Blood pressure outcomes are not reported here as there was no blood pressure entry criteria. RPM was associated with significant reduction in hbA1c at 12months, compared to baseline (8.8 vs 9.7, respectively; $n=24$; $p=0.05$). There was also a significant reduction in hbA1c at 6months compared to baseline (8.8 vs 10.4, respectively; $n=106$; $p<0.0001$), but not at 12months compared to 6months (8.8 vs 8.9, respectively; $n=23$; $p=0.78$).

CONCLUSIONS: Based on these initial data, RPM leads to improved diabetes control which is sustained at 12months. Data collection is ongoing and we expect to report 12month findings for a sample size of approximately 100 patients by the time of presentation in May 2019. RPM is an effective tool for improving diabetes management and delivering inter-visit care to patients of diverse geographic and socioeconomic backgrounds, affording improved chronic disease control in a patient-centered fashion. The user-friendly design and the healthcare providers' ability to provide inter-visit care with this technology, coupled with the sustained benefit on chronic disease control as measured by hbA1c, suggests that this form of care can reduce barriers to care and improve outcomes for otherwise vulnerable and underserved populations.

A BARBER-PHARMACIST INTERVENTION COULD REDUCE CVD EVENTS AT 10 YEARS IN HYPERTENSIVE NON-HISPANIC BLACK MEN: THE LOS ANGELES BARBERSHOP (LA BARBER) TRIAL

Kelsey B. Bryant¹; Brandon K. Bellows¹; Dhruv S. Kazi⁴; Valy Fontil²; Joanne Penko³; Ciantel A. Blyler⁵; Kathleen Lynch⁵; Norma B. Moy⁵; Joseph Ebinger⁵; Florian Rader⁵; Kirsten Bibbins-Domingo³; Andrew E. Moran¹.

¹Columbia University Medical Center, New York, NY; ²University of California San Francisco, San Francisco, CA; ³University of California, San Francisco, San Francisco, CA; ⁴Beth Israel Deaconess, Boston, MA; ⁵Cedars Sinai, Los Angeles, CA. (Control ID #3183887)

BACKGROUND: Pharmacist-driven blood pressure (BP) management in barber shops showed >20mmHg reductions in systolic BP over one year in Non-Hispanic black men with uncontrolled hypertension compared to the hypertension education-only control arm in the LA BARBER trial. However, the long-term potential to prevent cardiovascular disease (CVD) events using pharmacist-barber collaborations in this high-risk, vulnerable population is unknown.

METHODS: We used the microsimulation version of the CVD Policy Model to project the expected 10-year reduction in CVD events (stroke, myocardial infarction, or angina) if the LA BARBER intervention BP reduction persisted past the 12-month trial observation period. We simulated a hypothetical LA BARBER-eligible cohort of 10,000 Non-Hispanic black men sampled from the U.S. National Health and Nutrition Examination Surveys. Based on published literature, we assumed 43% of patients discontinued treatment after the first year in the base-case analysis. In an alternate scenario, all patients were fully adherent to medications for the entire 10 years. We assumed age-related changes in BP occurred regardless of treatment and that no other BP management occurred outside of the interventions during the time horizon.

RESULTS: The baseline characteristics of the simulation cohort were similar to the LA BARBER trial; mean baseline age was 54.1 years (LA BARBER 54.5 years) and mean baseline BP was 155/91 mm Hg (systolic/diastolic) (LA BARBER 154/91mm Hg). At one year, the model simulated mean BP reductions of -31.6/-16.7 mm Hg in the barber-pharmacist intervention (LA BARBER -28.6/-17.8 mm Hg) compared with control of -7.4/-4.0 (LA BARBER -7.2/-3.3) [resulting control rates 68% intervention (equal to LA BARBER), 7% control (LA BARBER 11%)]. At 10 years, the base-case analysis showed 29% hypertension control in the barber-pharmacist intervention arm compared to 0% in the control arm. In the full adherence scenario, control was 49% in the barber-pharmacist intervention arm and 2% in the control arm. Compared with the control arm, we projected about 300 CVD events averted over ten years in the barber-pharmacist intervention in the base-case scenario and 500 events averted in the full adherence scenario.

CONCLUSIONS: Our model predicted a reduction of about 300-500 CVD events in 10,000 LA BARBER-eligible Non-Hispanic black men over 10 years with the pharmacist intervention compared with an education-only control. A barber-pharmacist collaborative intervention delivered to Non-Hispanic black men with hypertension could potentially reduce CVD outcome disparities between Non-Hispanic black men and other U.S. ethnic groups. Further analyses will assess the cost-effectiveness and scalability of the labor-intensive BARBER hypertension treatment intervention.

A COMMUNITY HEALTH WORKER PROGRAM TO REDUCE CARDIOVASCULAR RISK IN UNDERSERVED RURAL COMMUNITIES

Samuel Cykert¹; Carmen Samuel-Hodge²; Audrina J. Bunton²; Sallie D. Allgood³. ¹University of North Carolina, Chapel Hill, NC; ²The UNC Gillings School of Global Public Health, Chapel Hill, NC; ³UNC School of Nursing, Chapel Hill, NC. (Control ID #3182956)

BACKGROUND: Cardiovascular disease (CVD) remains the leading cause of death throughout the U.S. The burden of CVD is particularly onerous in North Carolina which consistently ranks near the bottom tertile of CVD mortality among states. CVD-related death is worse in rural NC counties. Although no funds were appropriated, the creation of a community health worker (CHW) workforce as a vehicle for community outreach to improve prevention, adherence, and lifestyle was emphasized in the Affordable Care Act (ACA). In this report, we describe results from the Carolina Heart Alliance Networking for Greater Equity Project. The study objective was to evaluate the effectiveness of a CHW-delivered lifestyle program on intermediate health outcomes and lifestyle changes that could reduce CVD risk among underserved rural populations. CHWs were based in two public health departments (PHD) and two federally-qualified health centers (FQHC).

METHODS: Recruitment of participants to this pre-/post-test study involved two main strategies. FQHC-based CHWs were given a list of patients noted to have a CVD risk factor consistently uncontrolled. The PHD-based CHWs presented information sessions at community events and engaged interested individuals to participate. All consented individuals had their blood pressure measured. In the preparatory phase of the study, we started with modules from an evidence-based intervention targeting physical activity, a Mediterranean-like dietary pattern, medication adherence, and smoking cessation. We adapted program materials with input from a local community advisory board then developed a protocol for CHWs to deliver these modules to participants during 4 monthly sessions in participants' homes. Participants also received three phone calls for reinforcement mid-way between each session.

RESULTS: To date, 203 participants have completed the intervention. Mean age was 59 years (SD +/- 11.8); 91% were Black and 76% were women. At baseline, 72 participants had elevated blood pressure (systolic blood pressure (SBP) >140 mmHg or diastolic blood pressure (DBP) >90 mmHg) despite receiving regular clinical care. Post-intervention only 37 still had elevated blood pressures. The average decrease in SBP for all participants was 5mmHg (SD +/- 18) and DBP 2.4 mmHg (SD =/ 11). With Mediterranean-like dietary advice (without specific caloric restriction), 60% of participants lost weight; average weight loss among all participants was 2.7 lbs. (SD +/- 17) over 3 months. Self-reported dietary changes included an average increase of fruit-vegetable servings of 0.86 per day (SD +/- 1.9) and a 0.5 increase in weekly intake of nuts (SD +/- 0.95). Physical activity increased by an average of 23 minutes per week (SD +/- 187).

CONCLUSIONS: CHW outreach in underserved rural communities effectively delivered an evidence based intervention that improved intermediate health measures and life-style likely to lead to long term CVD risk reduction.

A COMMUNITY SUPPORTED AGRICULTURE INTERVENTION FOR HEALTH CENTER PATIENTS: A RANDOMIZED CLINICAL TRIAL

Seth A. Berkowitz¹; Jessica O'Neill²; Edward Sayer³; Naysha N. Shahid⁴; Maegan Petrie³; Sophie Schoubroeck²; Megan Saraceno²; Rochelle Bellin². ¹UNC School of Medicine, Chapel Hill, NC; ²Just Roots, Greenfield, MA; ³Community Health Center of Franklin County, Greenfield, MA; ⁴Massachusetts General Hospital, Boston, MA. (Control ID #3182962)

BACKGROUND: Socioeconomically vulnerable individuals often face poor access to nutritious food and bear a disproportionate burden of diet-related chronic illness. We sought to determine whether participation in a community supported agriculture intervention that subsidized healthy food could improve diet quality.

METHODS: We conducted a randomized clinical trial (NCT03231592) from May 2017 to December 2018. Adults at a community health center in central Massachusetts were eligible if they had a BMI > 25 kg/m² in the past year. Individuals were randomized to receive either subsidized participation in a community supported agriculture intervention (which provided a weekly box of farm produce from June to November) for 2 years, or usual care plus healthy eating information (control group). The primary outcome was the Healthy Eating Index 2010 (HEI) total score, and secondary outcomes were the HEI sub-scores. Assessment of HEI was made using three 24-hour recalls per participant per season. Higher total HEI score (range: 0-100) and sub-scores represent 'better' dietary quality. A 3 point difference in HEI total score is clinically significant. Intention-to-treat analyses compared HEI scores between the intervention and control group, accounting for repeated measures with generalized estimating equations.

RESULTS: There were 122 participants for analysis. The mean age of participants was 50.3 (SD: 13.6) years, 82% were women, 88% were non-Hispanic white, and there were no significant differences in baseline characteristics between the intervention and control groups. Baseline HEI total score was 53.9 (SD: 15.3) in the control group and 55.1 (SD: 15.2) in the intervention group ($p=.68$). The intervention increased the mean HEI total score relative to the control group (4.3 points higher, 95%CI 0.5 to 8.1; $p=.03$). Analyses of the HEI subscores showed that this was driven by greater consumption of vegetables and fruits, and lower consumption of 'empty' calories like sugar-sweetened beverages (Table).

CONCLUSIONS: A community supported agriculture intervention resulted in clinically meaningful improvements in diet quality for health center patients. Subsidized community supported agriculture may be an important intervention for vulnerable individuals.

A COMPARISON OF APIXABAN IN PATIENTS WITH ADVANCED CHRONIC KIDNEY DISEASE AND END STAGE RENAL DISEASE

Rajendrakumar C. Patel²; Kyle James¹; Jason Cobb²; Traci Leong³.

¹Emory University Hospital Midtown, Atlanta, GA; ²Emory University School of Medicine, Atlanta, GA; ³Emory University, Atlanta, GA. (Control ID #3184895)

BACKGROUND: Many patients with end stage renal disease (ESRD) or advanced chronic kidney disease (CKD) have conditions for which the appropriate treatment is anticoagulation. These conditions include atrial fibrillation/flutter and deep vein thrombosis/pulmonary embolism (DVT/PE). Classically, the oral anticoagulant of choice for patients with advanced renal disease and these conditions has been warfarin. The use of warfarin can be challenging, but newer direct oral anticoagulants are available for use. Apixaban, a direct oral anticoagulant, is potentially appropriate for use in patients with advanced renal disease as it is predominantly metabolized by the liver. Prospective studies of apixaban to date have excluded patients with advanced renal disease.

METHODS: A retrospective analysis by manual chart review was performed using data from a four-hospital system. Patients with diagnoses of either CKD 4, CKD 5, or ESRD who were ordered apixaban while hospitalized were identified. Hospitalizations occurred over 5.5 years. Patients were manually excluded if they never received a dose of apixaban or had an estimated glomerular filtration rate (GFR) greater than 30. Three independent physicians reviewed physician/provider/nursing notes, lab results, and medication administration records. Additionally, imaging reports were reviewed for therapeutic failures.

RESULTS: Of 508 encounters identified, 49 were excluded. Of the remaining 459 encounters, 171 had CKD and 288 had ESRD. There were 14 bleeding complications in the CKD group and 16 in the ESRD group ($p = 0.36$). The average number of red blood cell units transfused was 2.38 in the CKD group and 1.63 in the ESRD group ($p = 0.027$). Deaths occurred in 4 CKD encounters and 7 ESRD encounters ($p = 1.0$). One death was attributed to bleeding and this was in the ESRD group. Regarding therapeutic failure, there were no strokes, DVTs, or PEs in the CKD group, but there were 4 strokes observed ($p = 0.30$) and 3 DVTs or PEs observed ($p = 0.29$) in the ESRD group.

CONCLUSIONS: Our study suggests that there was no significant difference in risk of bleeding or therapeutic failure between CKD and ESRD patients. One strength of this study is its inclusion of multiple hospitals serving different populations. Limitations of this study include its retrospective nature and its restriction to the inpatient setting. An additional limitation is the use of encounter-level data rather than patient-level data. While randomized controlled trials are ultimately needed to properly address the safety of apixaban in CKD

and ESRD, our study may be helpful to providers in their decision-making in the meantime.

A CROSS-SECTIONAL STUDY USING CASE-BASED SKILLS ASSESSMENT TO MEASURE QUALITY OF INTEGRATED COMMUNITY CASE MANAGEMENT CARE DELIVERED BY VILLAGE HEALTH WORKERS IN BUGOYE, UGANDA

James S. Miller¹; Rapheal Mbusa²; Stephen Baguma²; Palka R. Patel³; Michael Matte²; Moses Ntaro⁴; Shem Bwambale⁵; Sara Mian McCarthy⁶; Jessica Kenney¹; Daniel Guiles¹; Edgar M. Mulogo⁴; Geren Stone¹. ¹Massachusetts General Hospital, Cambridge, MA; ²Global Health Collaborative, Mbarara, Uganda; ³Indiana University School of Medicine, Indianapolis, IN; ⁴Mbarara University of Science and Technology, Mbarara, Uganda; ⁵Bugoye Health Center, Bugoye, Uganda; ⁶UNICEF, New York, NY. (Control ID #3180333)

BACKGROUND: Village health workers (VHW) in 8 villages in Bugoye subcounty, Uganda provide Integrated Community Case Management (iCCM) care to children under 5 years old. In iCCM, VHWs assess and treat malaria, pneumonia, and diarrhea using a clinical algorithm. Study objectives included: 1) quantify VHWs' clinical performance and adherence to the clinical algorithm; 2) assess impact of formal education on skills assessment performance; 3) compare VHWs' performance as measured by the skills assessment exercise to prior clinical record review data (Miller et al. Malaria Journal 2018 17:99).

METHODS: All 36 VHWs agreed to complete the skills assessment exercise. This exercise included video cases depicting a caregiver of a sick child being interviewed, brief case vignettes portraying children with or without "danger signs" of severe illness, and reading mock rapid diagnostic tests (RDT) for malaria. Video cases were scored on completion of all steps in the clinical algorithm and a subset of "critical steps" required to achieve correct clinical management. Results were analyzed in Stata, with t-tests used to assess the association between formal education and performance.

RESULTS: Of the VHWs, 53% were women; 31% had completed primary school only and 69% some or all of secondary school. For cases of uncomplicated diarrhea and pneumonia, completion of all correct steps was low (19% and 6%, respectively), due to failure to address all recommended health education topics; completion of critical steps was high (92% and 97%, respectively). In a case of fever with a negative RDT, 100% of VHWs completed all correct steps. In a case of pneumonia with danger signs, 56% of VHWs completed all correct steps, while 89% completed all critical steps. Inappropriate use of antibiotics or antimalarials was low in all cases (0-3%). VHWs correctly classified 82% of brief case vignettes for children with or without danger signs. VHWs read 97% of mock RDTs correctly. There was no evidence of a difference in performance (measured by total correct management steps in the video cases and by a weighted overall performance metric) between VHWs with primary school education and with some or all of secondary school ($p=0.76$ and $p=0.89$, respectively). Rates of completion of critical steps in the cases were similar to prior assessment via clinical record review for uncomplicated diarrhea (92% vs. 97%) and uncomplicated pneumonia (97% vs. 95%) but quite different for fever with negative RDT (100% vs. 44%).

CONCLUSIONS: VHWs often omitted recommended health education topics, but otherwise demonstrated high quality of care in the video cases, recognition of danger signs, and reading RDTs. Level of formal education did not appear to influence performance. The difference in performance between data sources for fever with negative RDT may have resulted from training prompted by the prior results, direct observation during this present study, or incomplete clinical record-keeping.

A DECISION AID ON MAMMOGRAPHY SCREENING FOR WOMEN AGED 75 AND OLDER REDUCES SCREENING

Mara A. Schonberg¹; Roger B. Davis¹; Mary Beth Hamel¹; Gianna Aliberti¹; Alicia R. Jacobson¹; Maria Karamourtopoulos¹; Michele Hayes²; Christina C. Wee¹; Edward R. Marcantonio¹; Carmen L. Lewis³; Christine Kistler². ¹Beth Israel Deaconess Medical Center, Boston, MA; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³Univesrity of Colorado, Denver, CO. (Control ID #3168057)

BACKGROUND: The utility of breast cancer screening in later life varies according to women's life expectancy, breast cancer risk, and preferences. To improve informed, value-concordant breast cancer screening in later life, we conducted a clustered randomized trial to test the effectiveness of a mammography decision aid (DA) containing information on outcomes of screening, life expectancy, competing mortality risks, and a values clarification exercise.

METHODS: We recruited English speaking women ages 75-89 years with an upcoming appointment with their PCP without a history of breast cancer or dementia from 11 diverse primary care practices in Massachusetts (MA) and North Carolina (NC). Eligible women were screened in the past 24 months but not in the past 6 months. A research assistant (RA) administered a pre-visit questionnaire to participants on their intentions to be screened, health, breast cancer risk factors, and sociodemographic characteristics. Before the visit, the patient's PCP was randomized to either the pamphlet DA (intervention arm) or to a home safety pamphlet (HS, the control arm); subsequent participants from each PCP remained in the same arm. After the visit, the RA administered a post-visit questionnaire on screening intentions and knowledge. Participants were followed for 18 months for receipt of screening (i.e., at least 2 years since last mammogram). To examine the DA's effects, we fit marginal logistic regression models using generalized estimating equations to allow for clustering by PCP. We included PCP panel size, site, patient life expectancy, and 5-year Gail breast cancer risk in our models.

RESULTS: Of 1,031 eligible women contacted, 541 (53%) from 136 different PCPs consented to participate; 281 patients received the DA and 260 received HS. Patients in each arm were well-matched; 80% were from MA; 54% from community (vs. academic) sites; 38% had <10 year life expectancy; mean 5-year breast cancer risk was 2.2% (+/- 1.1%); 79% were non-Hispanic white; and 62% were college graduates. Post-visit, 87% of women who received the DA found it helpful and 95% would recommend it to a friend. Women in the DA arm were more likely to lower their intentions to be screened from pre to post visit (25% of women in the DA arm lowered their intentions vs. 17% in the HS arm, $p=0.03$), were more knowledgeable about screening (mean knowledge score 6.1 vs. 5.3 [out of 10 questions], $p<0.001$), and were more likely to have a discussion on mammography's pros and cons documented by their PCP (30% vs. 12%, $p=0.001$). After 18 months, 4% fewer in the DA arm were screened (57% vs. 61%, $p=0.03$). In MA where 74% of women in the control arm were screened, the DA was associated with a 12% reduction in screening ($p=0.006$); we found no difference in NC where screening in the control arm was low (23%).

CONCLUSIONS: Our mammography DA was perceived as helpful, improved older women's knowledge and discussions about screening, and led to fewer women aged 75-89 years being screened with mammography.

A FLUID DISCHARGE: LIQUID OPIOIDS AND OTHER RISK FACTORS THAT CONTRIBUTE TO EXCESSIVE OPIOID PRESCRIPTIONS FROM A HOSPITAL MEDICINE SERVICE

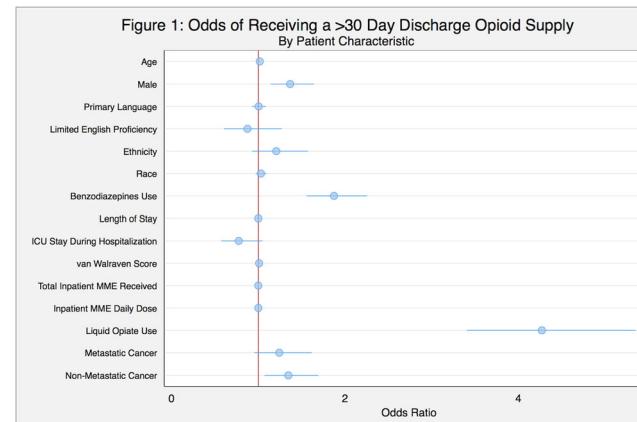

Nicholas Iverson; Nader Najafi; Yumiko Abe-Jones; Margaret Fang; Kirsten Kangelaris; Priya A. Prasad; Catherine Lau. UCSF, San Francisco, CA. (Control ID #3173256)

BACKGROUND: Recently enacted policies in multiple states have placed restrictions on opioid prescription days given the risk of development of chronic opioid therapy with prolonged opioid prescriptions. However, there are still patients who receive an excessive number of opioid prescription days after discharge from the hospital. We studied this population retrospectively to understand which patient-level risk factors contribute most to being an outlier of excess opioid prescribing on discharge from a hospital medicine service.

METHODS: We used the electronic health record to identify all patients hospitalized on the acute care medical service at a 600-bed tertiary care hospital from years 2012-2018. Patients were included if they received an opioid prescription both while hospitalized and on discharge and data were obtained on patient demographics, medication administration, and diagnosis codes. All opiate prescriptions were standardized to morphine milligram equivalents (MMEs). Days of opioids prescribed on discharge was calculated by the discharge prescription signature and number of pills. Patients were excluded if ICD9 or 10 codes for cancer-related pain or sickle cell disease were documented, or who were on hospice or followed by the palliative care service. Patients were categorized as receiving ≤ 14 days of opioids, 14 to 30 days of opioids, or >30 days of opioids. We then performed a multivariable logistic regression to assess for factors associated with longer opiate prescriptions.

RESULTS: We identified 9,275 medical inpatients prescribed opioids both during the hospitalization and on discharge who were eligible for the analysis. By the discharge prescription signature, 6,001 (64.7%) patients were prescribed less than 14 days, 2,688 (29.0%) received 14-30 days, and 586 (6.3%) received >30 days. Factors associated with receiving a >30 day supply include: being discharged with liquid opioids (OR 4.3 [3.4-5.4]), being on benzodiazepines prior to admission (OR 1.9 [1.6-2.6]), being male (OR 1.4 [1.1-1.6]), and having non-metastatic cancer (OR 1.3 [1.1-1.7]) (Figure 1). The maximum number of days prescribed was 1,875 days.

CONCLUSIONS: Patients prescribed liquid formulations of opioids were substantially more likely to have a prolonged duration of opiates supplied at discharge.

A MIXED METHODS ANALYSIS TO EVALUATE EMERGENCY DEPARTMENT (ED) WAIT TIME DISPARITIES

Jaya Aysola; Sean Foster; Mira Mamtani; Justin Clapp; Matthew Kearney; Eve Higginbotham. University of Pennsylvania, Philadelphia, PA. (Control ID #3185263)

BACKGROUND: We identified a significant disparity in ED wait times among patients eventually admitted to the hospital. Evidence reveals ED wait times influence patient satisfaction, length of stay, care quality, and hospital costs. This study aimed to identify key contributors to this inequity.

METHODS: We examined non-trauma patients admitted to the hospital that went through the ED from November 2017 to May 2018 (n=1531) and compared all time-stamped points along the patient's path from ED arrival to their departure to an inpatient floor, by race/ethnicity. We estimated with linear regression models the relationships between ED wait times, and the following patient- and ED-level characteristics: race/ethnicity, age, gender, comorbid conditions, insurance status, primary language, having a primary care provider, a prior ED visit within the past 30 days, assigned triage score (ESI), same day outpatient visit, call-in referral, admitting service and unit, degree of ED overcrowding, and the presence of provider in triage. Guided from our findings, we then collected and analyzed data from: 1) semi-structured interviews with patients (n=12); 2) general 2-hour observations of the ED (n=8); and 3) provider observations and semi-structured interviews (n=9). Providers were assigned groups based on their wait-time disparities and we selected at least two providers from each group to participate in the study. Team members were blind to provider groupings until the analysis was complete. A minimum of 25% of the sampled from each data source was double- or triple-coded to ensure interrater reliability.

RESULTS: We isolated the disparity to between when the ED provider sees the patient and requests a bed. After adjusting for the patient- and ED-level characteristics noted above, racial/ethnic ED wait time disparity attenuated but remained significant. We found a consistent pattern of communication between providers (physician or nurse) and patients, depending on whether they were of similar race/ethnicity (concordant pair) or not (discordant pair). Among discordant pairs, providers were more likely to interrupt patients, ignore patient requests, and have less eye contact. Among concordant pairings, providers exhibited a greater level of advocacy, such as tracking down labs or a consultant. Providers without significant ED wait time disparities, articulated objective criteria, such as triage scores (ESI), for prioritizing which patients they see first. In contrast, only one provider from the groups with significant wait time disparities mentioned ESI, only to question its validity in prioritizing patients.

CONCLUSIONS: Our findings suggest that both provider-patient interactions and the provider's approach to prioritizing care play a significant role in ED wait time disparities. This study yields actionable provider-specific contributors to the wait time disparities that may apply to broader set of quality metrics.

A MULTICENTER STUDY OF THE FORMAT AND CONTENT OF INTERNAL MEDICINE MORNING REPORT

Dan Heppe¹; Albertine Beard²; Brian Kwan³; Michael Ong⁴; Azadeh Lankarani-Fard⁴; Paul B. Cornia⁵; Matthew Tuck⁶; Craig G. Gunderson⁷. ¹Eastern Colorado Veterans Health Administration, Denver, CO; ²Minneapolis VA, Minneapolis, MN; ³University of California, San Diego, San Diego, CA; ⁴UCLA, Los Angeles, CA; ⁵Seattle VA, Seattle, WA; ⁶Department of Veterans Affairs Medical Center, Washington, DC; ⁷Yale Medical School, West Haven, CT. (Control ID #3185273)

BACKGROUND: Morning report has long been considered a core component of internal medicine residency training. There are multiple potential formats and topics for morning report and few prior studies have described the content and structure of contemporary morning reports.

METHODS: We conducted a prospective observational study of morning report at seven different Veterans Affairs academic medical centers. Each participating site observed a series of morning reports and collected data on the number and type of learners, the number and background of attendings, and the format of report. For case based reports the amount of time on different aspects of the case

was recorded as well as the ultimate diagnosis when known. We also recorded other content areas such as medical literature, ethics, quality and safety, and high-value care.

RESULTS: We observed 136 morning reports from 7 different academic medical centers across the country. Reports included a mix of residents, interns and medical students, while 26.5% included non-physician learners. The most common attending was a hospitalist (93.3%) followed by internal medicine sub-specialist (43.3%) and general internist (31.6%). Most were led by a chief resident (83.8%). The most common format was case-based (84.6%) with the remaining being a mix of EBM, journal club, and game based. Most case based reports were prepared (86.1%) as opposed to "live" reports. On average, the most time was spent on differential diagnosis and testing (12.0min), didactics (9.5min) and history (7.3min). Most reports used PowerPoint (85.6%) and 70.4% had more than 15 slides. Medical literature was only referenced in 35.3% of reports, most commonly as narrative reviews or professional guidelines. Original research was only discussed in 18.4% of reports and systematic reviews in 5.9%. Psychosocial issues were discussed in 8.0% of reports, quality and safety in 7.3%, and high value care in 7.3%. Ethics was rarely discussed. No report went to the bedside. Of the 115 case based reports, 102 had known diagnosis and 13 were unknown. Of the known diagnoses, the most common categories were infectious disease (17), cardiology (15), nephrology (12) and rheumatology (8) which together accounted for more than half of the cases. Individual diagnoses were highly varied, with 92 diagnoses that occurred only once and 10 that occurred multiple times. 50% of diagnoses were rated as rare.

CONCLUSIONS: In our series, the primary format for report continues to be case based, which are primarily prepared prior to report by the chief resident and employ Power Point. One fourth of reports include non-physician learners. For case based reports, history, differential diagnosis, testing and didactics are the most emphasized areas. Few reports discussed ethics and none involved bedside teaching. The most common attending present was a hospitalist. Individual diagnoses were highly varied and favor rare diagnoses.

A NATIONAL EVALUATION OF PATIENT PORTAL USE AS REPORTED BY PRIMARY CARE PROVIDERS TO THE CENTERS FOR MEDICARE AND MEDICAID SERVICE

Jorge A. Rodriguez¹; Stuart R. Lipsitz²; Courtney R. Lyles³; Lipika Samal². ¹Lawrence General Hospital, Somerville, MA; ²Brigham and Women's Hospital, Boston, MA; ³University of California San Francisco, San Francisco, CA. (Control ID #3184455)

BACKGROUND: Patient portals expanded under the Meaningful Use (MU) Program, which provided over \$35 billion for them and led to provision of portals by 90% of providers. Yet this has not led to high uptake by patients, which has been attributed to sociodemographic factors in studies conducted at single institutions. The goal of our study was to correlate national data on broadband access with patient portal use, defined as number of patients who have used the portal to either view, download or transmit (VDT) information, after controlling for sociodemographic characteristics.

METHODS: We performed a retrospective study combining National Provider Identifier (NPI) data from 2016 MU public use files with NPI database to identify provider's address. By linking these addresses with Google Maps Application Programming Interface, the American Community Survey, US Department of Agriculture, and Federal Communications Commission Form 477 we attributed the level of broadband access to each provider's census

tract. Broadband access was defined as the number of residential connections per 1,000 households by census tract. Our primary outcome was patient portal VDT for each primary care provider. We performed logistic regression with clustering by census tract.

RESULTS: Our sample contained 67,686 primary care providers representing 40,653,351 patients across 14,974 census tracts. At the census tract level, the mean reported portal viewing was 28%. Even after controlling for sociodemographic factors, the association between broadband access and portal use persisted (Table).

CONCLUSIONS: Despite nearly universal provision of patient portals, we found that only about a third of patients are using them. Previous studies at the healthcare system level have reported sociodemographic disparities in portal use. Our study provides the first national analysis of portal use and not only reaffirms this association but highlights the strong independent role of broadband access. Though significant efforts led to portal access, a focus on broadband, and patient training and input in development is needed to increase portal use and realize the benefits of patient facing technology.

A NOVEL PATIENT-CENTERED APPROACH TO INTIMATE PARTNER VIOLENCE IN PRIMARY CARE: RECOVERING FROM IPV THROUGH STRENGTHS AND EMPOWERMENT (RISE)

Megan R. Gerber^{1, 2}; Sara B. Danitz³; Katherine Iverson^{3, 2}.

¹Boston University, Jamaica Plain, MA; ²Boston University, Boston, MA; ³Women's Health Sciences Division, Jamaica Plain, MA. (Control ID #3177218)

BACKGROUND: Intimate partner violence (IPV) is a public health problem common among women Veterans. IPV causes injury, chronic illness and health inequity, yet intervention in primary care remains challenging. Research shows that women prefer a self-directed approach to advocacy and recovery. To address this need, we developed "Recovering from IPV through Strengths and Empowerment" (RISE), a brief (30-60 min), innovative variable-length intervention for women with IPV. RISE is rooted in motivational-interviewing and empowerment principles and consists of 6 modules (Table) delivered in up to 6 sessions in primary care settings. Patients prioritize and select modules based on their unique needs. RISE was systematically developed and refined with iterative input from women Veterans and providers in the Veterans Health Administration (VA). We present preliminary results of the initial VA trial.

METHODS: Women with past-year IPV were recruited to participate in an open trial. Social workers and psychologists delivered RISE on-site, evaluation was conducted using a mixed methods approach. We collected pre- and post-treatment measures of psychosocial health (general self-efficacy [GSE], patient activation measure [PAM], valued living [VLQ], and depression [CES-D]). We also conducted semi-structured exit interviews with women after RISE receipt. Interviews were analyzed with a rapid qualitative approach. Enrollment is ongoing.

RESULTS: To date, 10 women Veterans have completed the trial (mean age = 29, SD=12). The sample was 50% White, 40% Black, and 10% Latina. 80% opted to receive at least 5 sessions, and 60% of the sample chose to receive all 6 RISE sessions. From pre- to posttreatment, participants showed significant reductions in depressive symptoms and increases in self-efficacy, PAM, and valued living, with medium effect sizes across outcomes (Cohen's D range: .54 - .72). Women expressed high satisfaction with RISE, they 1) liked ability to choose the content delivered, 2) felt RISE provided validation of their IPV experiences, 3) were empowered to be more assertive, and 4) expressed that RISE improved

understanding of the impact of IPV on their health, which promoted confidence in accessing additional services, congruent with increased PAM score.

CONCLUSIONS: Preliminary findings support the clinical utility and acceptability of RISE in primary care. Increases in self-efficacy, patient activation, and valued living scores suggest RISE may promote self-efficacy, quality of life, and even health equity as women are enabled to engage in care and access services. Recruitment continues, we anticipate a larger sample by Spring 2019. Future work includes an RCT which follows this open trial.

A NOVEL PROGRAM TO COORDINATE CARE FOR SOCIALLY VULNERABLE INDIVIDUALS WITH COMPLEX HEALTH NEEDS: EVALUATING STRUCTURE AND PROCESSES OF CONNECT 2 CARE

Dailys Garcia-Jorda²; Kerry McBrien¹; Alicia J. Polachek²; Celise Ritter-Rattray²; Hasham Kamran²; Gabriel E. Fabreau¹. ¹University of Calgary, Calgary, AB, Canada; ²Cumming School of Medicine, University of Calgary, Calgary, AB, Canada. (Control ID #3186129)

BACKGROUND: Background: Socially vulnerable individuals have higher mortality and acute care use than the general population and require specialized services to address complex health and social needs. *Connect 2 Care* (C2C), a mobile outreach program launched in November 2015, seeks to improve care coordination between acute and community care for socially vulnerable individuals with high acute care use, often also experiencing housing insecurity in Calgary, Canada. We are conducting a comprehensive mixed-method program evaluation to investigate the C2C program's structure, processes and outcomes to inform its potential sustainability. We directed part of our qualitative evaluation to document program structure and processes, and understand frontline staff daily activities, perceptions and experiences of caring for their clients.

METHODS: Methods: We conducted observations of C2C staff from February to June 2018. We sampled multiple settings and different times of the day and days of the week to examine the C2C team's: 1) structure, including infrastructure, personnel and partnerships and; 2) processes, including daily activities, services, interactions, and challenges. Observations were triangulated with C2C team members' qualitative semi-structured interviews, from October 2018. We conducted an inductive thematic analysis of observation field notes and interview transcripts and recorded themes that emerged using an iterative consensus process among all authors.

RESULTS: Results: We analyzed 36 cumulative hours of observation and nine interviews (three nurses, four health navigators, and two managers). Our analysis revealed how C2C staff explicitly work to 'fill the gap' between acute and community care, and also between healthcare and social services (i.e., housing). System-level healthcare and social challenges became evident throughout the observations and interviews, as participants struggled daily to access necessary care and social services for their clients. The C2C team's comprehensive healthcare and social system knowledge and commitment to their clients were core structural program elements, as were specified skills, training and intrinsic motivation of team members. These elements supported core program processes including client rapport building and navigation between many agencies and services. The program's novelty emerged as it addressed client's needs through a client-centred, harm-reduction approach, providing support, advocacy, and building relationships between acute and community care, and with other organizations.

CONCLUSIONS: Conclusions: We identified core elements of C2C program structure and processes, as well as strengths, challenges, and limitations that modulate its effectiveness. Our findings suggest core program elements are likely replicable but depend on both intrinsic qualities and motivations among program staff, as well as structural and interpersonal supports from the healthcare and social system broadly.

A PEER OBSERVATION OF TEACHING PROGRAM TO OPTIMIZE FEEDBACK ACCEPTANCE BY FACULTY

Alice Tang¹; Sydney Katz²; Stephanie J. Tang³; Kendrick Tang⁵; David Stern⁴. ¹Weill Cornell Medical College, New York, NY; ²Weill Cornell, Brooklyn, NY; ³Weill Cornell Medicine | NewYork-Presbyterian Hospital, Long Island City, NY; ⁴New York University, New York, NY; ⁵Memorial Sloane Kettering, New York, NY. (Control ID #3184735)

BACKGROUND: Physicians are poor self-assessors in most domains, including teaching skills. However, self-assessment is essential for self-regulation and performance improvement through deliberate practice. The process by which one accesses, interprets, and accepts feedback is a complex process which involves a number of factors, conditions, and tensions. Optimizing these factors and conditions is essential for acceptance of feedback and improvement of skills. Peer observation of teaching (POT) has been shown to be a promising tool for improving teaching quality and confidence. The purpose of this phenomenological study is to explore the experiences of medicine faculty undergoing a POT program, consisting of in-person and video-based observation and feedback. The findings can be used to better understand how factors, conditions, and tensions can be optimized to enhance faculty self-assessment of teaching skills. Secondarily, the study aims to compare in-person with video-based peer observation and investigates how observing a peer's clinical teaching affects one's own teaching skills.

METHODS: A hermeneutic phenomenological approach was used to understand the "lived experiences" of faculty undergoing a novel POT program at an academic medical center in New York City. A comprehensive sample of ten participants was interviewed prior to and after completing the program. Participants were paired with a partner and each pair discussed teaching goals and observed one-another in both an in-person and video-based teaching session during ward rounds or precepting. Self-assessment, feedback, and goal setting followed each teaching observation. Interviews were transcribed and analyzed iteratively by two independent reviewers until thematic saturation was reached. Themes were presented to study participants during a focus group for member checking.

RESULTS: The median time as an attending physician for participants was 1.5 years, ranging between 0.5 to 5.5 years. Ninety percent of participants were observed during ward rounds. Features of the program that facilitated enhanced self-assessment and improved clinical teaching skills included the authenticity and structure of the program, partner credibility, matched educator competency, optimal balance between comfort and discomfort, and self-reflection. Many participants cited specific changes that they had made in their teaching behaviors as a result of this program.

CONCLUSIONS: The results of this study build upon the factors, conditions, and tensions identified in Sargent's informed self-assessment conceptual model and apply it to a faculty development program. Findings can aid other faculty development programs to optimize factors and conditions for feedback acceptance and improve clinical teaching skills through deliberate practice.

A PILOT STUDY OF A LOW-CARBOHYDRATE DIABETES PREVENTION PROGRAM AMONG ADULTS WITH PRE-DIABETES

Dina H. Griaudze^{1, 2}; Kaitlyn J. Patterson³; Tahoor Ansari¹; Patti Bihm³; Samuel Shopinski³; Caroline Richardson¹; Laura Saslow¹.

¹University of Michigan, Ann Arbor, MI; ²VA, Ann Arbor, MI; ³National Kidney Foundation of Michigan, Ann Arbor, MI. (Control ID #3183918)

BACKGROUND: Individuals with prediabetes can prevent or delay progression to type 2 diabetes by losing 5% of their body weight. The Center for Disease Control and Prevention's National Diabetes Prevention Program (NDPP) is a lifestyle change program proven to help individuals lose weight through adherence to a low-fat, calorie-restricted diet. Yet, low-carbohydrate diets may be more effective for weight loss and glycemic control among individuals with prediabetes. This pilot study examined the feasibility, acceptability, and preliminary weight loss efficacy of a Low-Carbohydrate Diabetes Prevention Program (LC-DPP) among individuals with prediabetes.

METHODS: This single-arm mixed methods pilot study was conducted at a large, academic primary care clinic. Inclusion criteria were: BMI 25 kg/m² and prediabetes (defined as HbA1c 5.7-6.4% and absence of diabetes). Eligible participants were identified by chart review and invited to participate by postal letter. We adapted the dietary information in the NDPP's curriculum (16 weekly core sessions, 8 bimonthly/monthly post-core sessions) and trained a lifestyle coach to teach participants to follow a very low carbohydrate diet (< 35 non-fiber grams of carbohydrates per day). Primary outcomes were feasibility (rate of recruitment) and acceptability (session attendance, qualitative interviews). Secondary outcomes were change in weight and hemoglobin A1c at 6- and 12-months.

RESULTS: Twelve percent of individuals (21/187) who were invited to participate enrolled in the study and had a mean age of 59 years, BMI of 34.2 kg/m², HbA1c of 5.9%. Over half (n=12, 57%) of participants were men. All individuals attended 3 or more core sessions and 67% (14/21) attended at least 9 core sessions. At 6 months, mean percent (SD) body weight loss was 4.5(5.0); 46% (10/21) of participants achieved 5% body weight loss and 27% (6/21) achieved 7% body weight loss. At 12 months, mean percent (SD) body weight loss was 5.9 (7.1); 43% of participants (9/21) achieved 5% body weight loss and 36% (8/21) achieved 7% body weight loss. HbA1c decreased by an average of 0.1% at 6 months (n=18) and by an average of 0.3% at 12-months (n=19) compared to baseline. Qualitative interviews (n=13) revealed themes of subjective health benefits (e.g. improved sleep) beyond weight loss and relative ease of learning a low-carbohydrate lifestyle. Barriers included social pressures and concerns about high dietary fat intake. There were no significant changes in physical symptoms (e.g. thirst, constipation). One participant suffered an ischemic stroke.

CONCLUSIONS: A LC-DPP is feasible and acceptable among individuals with prediabetes. At 12-months, mean weight loss among our pilot program participants was greater than mean weight loss among participants in traditional NDPPs, as reported in meta-analyses (5.9% vs. 4.0%). A large-scale comparative effectiveness trial is needed.

A PILOT STUDY OF A PHOTO-BASED INTERVENTION TO PROMOTE DIETARY DISCUSSIONS AMONG OLDER ADULTS WITH MULTIPLE CHRONIC CONDITIONS IN PRIMARY CARE

Jane Jih; Ying Wang; Liliana Chacon; Jasmin Woo; Antony H. Nguyen; Tung T. Nguyen; Christine Ritchie. UCSF, San Francisco, CA. (Control ID #3182021)

BACKGROUND: We know little about how to best communicate with older adults about optimal dietary behaviors for the self-management of multiple chronic conditions (MCC). In MCC self-management, photos can promote efficient information exchange and activate patients to more effectively communicate their complex lived experiences. Based on this premise, we conducted a pilot study to assess the feasibility and acceptability of a photo-based communication intervention to promote dietary discussions among older adults with MCC in primary care.

METHODS: We recruited older adults age 60+ with at least 2+ concurrent chronic conditions and their primary care providers (PCPs) from an urban academic primary care practice. We recruited patient participants from clinic waiting rooms, PCP referrals, and from a telephone survey focused on food insecurity and MCC. Ten days before the study clinic visit, patients received a 25-minute in-person training on photo-taking with a smartphone and then took photos in response to the prompt, "What aspects of your everyday life affect what you eat and how much you have to eat?" Patients received reminder calls or text messages to take 1-2 photos/day. One week before the visit, providers received a 5 minute in-person training about what to do when patients shared photos. Patients shared photos and their narrative to their PCP during the study clinic visit. Study clinic visits were audio-recorded. We also conducted separate audio-recorded patient and provider post-visit interviews to assess perspectives on the intervention. We used an iterative, grounded theory approach to analyze transcripts.

RESULTS: Nine patient-PCP dyads have completed the study to date. Patient participants were 44% female, 78% Latino or African American, and 67% completed high school education with mean age of 69 years old. PCPs on average had been in practice for 11 years since medical school (range 3-22 years) and saw on average 27 patients each week (range 7-60). 89% of patient-PCP dyads completed the intervention as trained. Patients shared 6 photos (range 5-8) on average. Visits lasted 22-39 minutes with 14-47% (average 23%) of the visit spent looking and discussing photos. 100% of patients definitely would like to share photos about health with their PCP again. 100% of PCP definitely [67%] or probably [33%] would like patients to share photos at future visits including photos related to medication use and home safety. Patient and PCP quotes illustrated the added value of the intervention (Table).

CONCLUSIONS: A pilot patient-centered photo-based intervention to promote diet-related discussions between older adults with MCC and their PCPs has shown high feasibility and acceptability. Future work will assess how a photo-based intervention can enhance patient-PCP communication about other contextual factors important in chronic disease management.

A PRAGMATIC TRIAL INTEGRATING ROUTINE SCREENING FOR ATRIAL FIBRILLATION IN OLDER PATIENTS DURING PRIMARY CARE VISITS: INITIAL ENROLLMENT DATA FROM THE VITAL-AF TRIAL

Steven J. Atlas¹; Jeffrey M. Ashburner¹; Steven A. Lubitz¹; Yuchiao Chang¹; Ana T. Trisini Lipsanopoulos¹; Leila H. Borowsky¹; Wyliena Guan¹; Wei He¹; Patrick T. Ellinor¹; David D. McManus²; Daniel E. Singer¹. ¹Massachusetts General Hospital, Boston, MA; ²University of Massachusetts Medical School, Worcester, MA. (Control ID #3185016)

BACKGROUND: Atrial fibrillation (AF) is often asymptomatic and sometimes diagnosed only at the time of a stroke. Efficient and scalable screening for AF may prompt appropriate initiation of oral anticoagulation to prevent strokes. A new pragmatic trial, VITAL-AF (ClinicalTrials.gov NCT03515057), will evaluate whether adding automated AF rhythm assessment as a vital sign among older adults

during primary care visits is an effective new standard of care.

METHODS: The study is being conducted within an academic primary care network in the United States that uses a single electronic health record (EHR). Randomization is at the practice-level with 8 practices randomized to AF screening and 8 to usual care. Patients 65 years and older attending an outpatient visit in a participating site with a physician or nurse practitioner are eligible. Screening is performed by medical assistants, not research personnel. All eligible patients are approached while checking vital signs and those who agree are screened using a single-lead ECG device (AliveCor, US). Screening results are documented in the EHR and clinicians are notified about patients with possible AF. Clinicians can discuss screening results with patients and manage AF at their discretion. All single-lead ECGs are reviewed by a cardiologist. The primary study endpoint is incident AF during a 1-year enrollment period which began July 31, 2018. Secondary outcomes include new oral anticoagulation prescriptions, ischemic stroke and major hemorrhage. Outcomes are based on EHR documentation. With a sample size of 16,212 patients per group, a baseline AF incidence of 1.6% and an 85% screening rate, the study will have 80% power to detect a 0.42% difference in AF incidence.

RESULTS: As of November 30, 2018, 11089 eligible encounters have occurred in intervention practices, with 9621 (86.8%) approached for screening by a medical assistant, and 8629 (77.8%) completing screening. Encounter data across intervention sites show high rates with modest variation (see table). Encounters where screening was declined average 8.7% (range 3.6-13.0% by site). Among 8716 eligible patients with encounters, 7141 (81.9%) have completed screening. Since patients are offered screening at all visits, 220 (62.2%) not initially screened were screened at a subsequent visit.

CONCLUSIONS: VITAL-AF is the first randomized clinical trial to embed AF screening into routine primary care in the US. Initial enrollment data show that adding automated AF rhythm assessment as a new vital sign among older, at-risk adults at primary care visits is feasible and accepted by patients. Outcome assessment will determine whether it is an effective new standard of care.

A PRE-IMPLEMENTATION STUDY OF HOSPITAL-BASED HEALTH PROFESSIONAL PERSPECTIVES ON PRESCRIBING OF MEDICATIONS FOR ALCOHOL USE DISORDER

Paul Joudrey¹; Benjamin Oldfield¹; Kimberly A. Yonkers²; Patrick O'Connor¹; E. Jennifer Edelman¹. ¹Yale School of Medicine, New Haven, CT; ²Yale School of Public Health, New Haven, CT. (Control ID #3186284)

BACKGROUND: Medications for Alcohol use disorder (MAUD) (acamprosate, naltrexone, and disulfiram along with off label gabapentin and topiramate) remain underutilized despite guideline recommendations and rising alcohol-related morbidity and mortality. Alcohol use disorder (AUD)-related hospitalizations are opportunities to initiate MAUD, but optimal implementation strategies are unclear. Using an implementation science framework, we assessed a multidisciplinary group of hospital-based health professional perspectives on prescribing MAUD among patients with AUD within the inpatient general medicine setting.

METHODS: We completed a pre-implementation mixed method study at Yale New Haven Hospital. We administered the first two scales (evidence and context) of the Organizational Readiness for Change Assessment (ORCA) survey. We evaluated median scores (five-point Likert scale, 1 = lowest readiness, 5 = highest readiness) across ten subscales to determine the highest and lowest subscale within the evidence and context scales. We conducted profession-specific focus groups among general medicine inpatient teams,

guided by the Consolidated Framework for Implementation Research (CFIR) and purposively sampled for variation by discipline and experience. We analyzed focus group transcripts using directed content analysis in accordance with the CFIR framework. We used the constant comparative method to identify emerging themes across the entire sample.

RESULTS: We completed seven focus groups with all 57 participants completing an ORCA survey (eight nurses, six nurse practitioners, ten physicians, ten social workers, eight physician assistants, nine pharmacists, and eight psychiatrists). Among participants, the median age was 34, 43 (75%) were female, and had a median of four years of experience. ORCA evidence subscale results showed high research evidence (median 4.0) but low patient preference (median 3.5) for MAUD. Context subscale results showed staff culture (median 4.0) to be supportive of implementation but low availability of resources for implementation (median 3.0). We identified four emerging themes. Across disciplines, there was limited knowledge and experience regarding MAUD. There was concern about patient barriers to accessing care following discharge and perceived low patient engagement. Participants viewed long term abstinence as the goal of treatment rather than reducing harm by reducing use. Participants reported existing care support systems for other chronic diseases (i.e. tobacco use) could be adapted to support MAUD utilization.

CONCLUSIONS: Among hospital-based health professionals, a lack of knowledge, a lack of patient treatment access following discharge, perceived low patient engagement, and a focus on abstinence reduced inpatient utilization of MAUD. Implementation interventions should aim to adapt existing care support systems, increase provider understanding of these medications, and support harm reduction rather than abstinence as a treatment goal.

A PRELIMINARY QUALITATIVE ANALYSIS OF FIBROMYALGIA CARE IN VA THROUGH NARRATIVES OF WOMEN VETERANS

Kristina M. Bogdan^{1, 2}; Erica R. Scioli^{1, 2}; Megan R. Gerber³. ¹VA Boston Healthcare System, Boston, MA; ²Boston University School of Medicine, Boston, MA; ³Boston University, Jamaica Plain, MA. (Control ID #3186398)

BACKGROUND: Fibromyalgia (FM) is a chronic disorder more common in women. It is characterized by widespread bodily pain, fatigue, and poor sleep. Prior studies have concluded that participants often feel unheard, demoralized, and invalidated by healthcare providers. Women Veterans are a rapidly growing population in the Veterans Health Administration (VHA), and their rates of FM exceed that of the general population. A better understanding of women Veterans' perceptions of care will inform patient-centered approaches to FM. Thus, we conducted a mixed methods study to better understand women Veterans' experiences with and preferences for VA FM care. The qualitative portion of the study data are presented below.

METHODS: Six, in-person, focus groups of women Veterans, who used VA primary care and had medical record-confirmed FM, were conducted. A clinical psychologist conducted all 6 groups using a semi-structured interview guide. The focus groups were transcribed and analyzed using a hybrid thematic approach. Codes were identified and grouped into themes. A second investigator reviewed the identified codes for congruence and differences were resolved. Finally, a third researcher, who was present at all focus groups, reviewed the codes and themes to achieve final consensus.

RESULTS: 22 women Veterans with FM participated in 6 focus groups. The mean age was 51.3 (range 30-76, SD= 11.6). Most of the patients were White (54.5%) and unemployed (77.3%). Most (72.7%) had a diagnosis of posttraumatic stress disorder (PTSD). The following 4 dominant themes emerged: 1) Challenge of living

with FM (women expressed profound fatigue and isolation as a result of unpredictable pain), 2) Invalidation (both healthcare providers and family/friends were dismissive of FM symptoms), 3) Health Behaviors (women expressed self-efficacy approaches to FM symptom management as well as avoidance of known triggers), 4) Trust in VA care (patients valued primary care providers [PCP] who listened and validated FM symptoms; patients expressed concern that their gender had resulted in inadequate FM care by other providers. When referring to participant VA treatment experiences, one said "I won't come in unless I'm desperate" while another illustrated a memory by saying "...they sent me to the pain management and the doctor told me that, you know, fibromyalgia wasn't a disease, it was mental."

CONCLUSIONS: Women Veterans encounter many challenges in functioning with FM and accessing care, they often felt disbelieved and invalidated. Many have developed knowledge of what triggers a flare and what helps them feel better. Women across focus groups expressed greater satisfaction and trust in VA care when their PCP showed interest in their condition and listened well. These findings support the need for a patient-centered approach to FM care.

A PROACTIVE TEXT MESSAGING INTERVENTION WITH MEDICATION ADHERENCE SUPPORT TAILED TO PRIMARY CARE POPULATIONS: A PILOT RANDOMIZED TRIAL OF GETREADY2QUIT

Gina R. Kruse^{2, 1}; Elyse Park^{2, 1}; Yuchiao Chang^{2, 1}; Jessica Haberer^{2, 1}; Lorien Abroms³; Naysha N. Shahid²; Sydney Howard²; Jennifer Haas^{2, 1}; Nancy A. Rigotti^{2, 1}. ¹Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³George Washington University, Washington, DC. (Control ID #3179241)

BACKGROUND: Text messaging is an effective aid to help with smoking cessation, but it is unclear how to integrate it effectively into primary care settings. We developed and tested an automated, proactive, text messaging program with 2 novel uses: 1) to enhance motivation for smokers not ready to quit and 2) to promote adherence to nicotine replacement therapy (NRT). We present feasibility and efficacy results for a 12-week pilot randomized controlled trial (RCT).

METHODS: We used proactive telephone calls to recruit adult daily smokers from 10/2017-10/2018 for a RCT. Randomization was stratified by clinic and smoker's plan to quit within 30 days. Enrollees were assigned to 1 of 4 groups: brief advice about treatment options and local services (BA), brief advice + text messages (TM), brief advice + 2-weeks of NRT by mail (NRT), or brief advice + TM + NRT (TM+NRT). Patients were surveyed by phone or email at 1-, 2-, 6- and 12-weeks.

RESULTS: We approached 1,544 potentially eligible patients, we reached 988 (64%). Of these, 527 (53%) declined, 32 (3%) dropped out before randomization, 276 (28%) were ineligible and 153 (15%) of those reached were randomized. Of these, 54% were women, mean age 53 years, 76% white, 12% African-American, 6% Hispanic, 5% other races, 54% on Medicaid, mean 15 cigarettes/day and 75% smoked <30 minutes from awakening. Overall, 31% screened positive for alcohol use disorder (single-item measure), 13% for substance use (single-item measure), 35% for depression (PHQ-2) and 55% for anxiety (GAD-2). Acceptance of treatments offered (BA, TM, and/or NRT) was 100%. Retention at the 12-week follow-up was 92% (n=140). A large majority of patients self-reported 1 quit attempt(s) (1clinical outcome), with no differences by group compared to BA (71%), TM (89%, p=0.13), NRT (82%, p=0.40), TM+NRT (81%, p=0.41). Past 7-day abstinence at 12-weeks was reported twice as often in the NRT, TM, and TM+NRT

groups, though differences were not significant compared to BA (11%), TM (29%, p=0.13), NRT (30%, p=0.07), and TM+NRT (22%, p=0.35). Groups offered NRT by mail were more likely to report NRT use compared to BA (51%), TM (63%, p=0.47), NRT (82%, p=0.011), and TM+NRT (76%, p=0.049). There was no difference in days of NRT use over the first 2 weeks between NRT only (4.6 days of NRT use) or NRT+TM (3.0 days, p=0.13).

CONCLUSIONS: This pilot RCT demonstrated feasibility as we recruited, treated, and retained smokers from a primary care network. Our uptake of 15% is comparable to other proactive outreach interventions for smokers. A proactive offer to have NRT mailed to patients' homes increased NRT use, even though many patients already had access to low-cost NRT from Medicaid. Adherence messages in the texting program did not increase NRT use. Proactively-delivered smoking cessation interventions that are offered outside office visits are feasible and hold promise for reducing smoking rates and promoting health in primary care populations.

A PROGRESSIVE-STAGE MODEL OF PATIENT ENGAGEMENT IN INNOVATION TEAMS: FROM VISITOR TO PARTNER TO ACTIVE CHANGE AGENT

Sophie Higgins¹; Mariam K. Atkinson³; Sara Singer². ¹Harvard T.H. Chan School of Public Health, Boston, MA; ²Harvard School of Public Health, Boston, MA; ³Harvard University, Boston, MA. (Control ID #3183975)

BACKGROUND: Patient engagement is recognized as vital for improving healthcare delivery. Increasingly, patients are collaborating with teams working to redesign healthcare processes. Yet, there is limited understanding of the ways patients' social identity (i.e., the way patients and other team members view patients in relation to a particular group) evolves over the course of involvement in healthcare innovation teams. This study explored the evolution of patient identity on innovation teams to help teams optimize patient engagement in improvement efforts.

METHODS: In 3 interdisciplinary teams that included patients across 3 health systems participating in an innovation collaborative, we observed weekly team meetings over 18 months and conducted 16 interviews with team members (4 health system staff, 4 physicians/physician leaders, 4 system engineers, 3 patients, and 1 administrative manager). In interviews, respondents addressed targeted questions about patient engagement, including perceptions of patient contributions to team progress and the evolution of patients' role over time. Field notes and interview transcripts were coded and analyzed using a grounded theory approach to identify major themes.

RESULTS: Qualitative data analysis led to the development of a framework that illustrates the process by which patient social identity evolves from visitor to partner to active change agent over the course of an innovation project. The process is driven by team members' (including patients') view of a patients' role, wherein both patient and staff's (i.e., non-patient team members) views of a patient's role on the team lead the patient to enact this role, as staff team members engage in behaviors and activities that reflect these views. This dynamic interaction between patients' role enactment and staff activities results in patient contributions that impact the work of the team. Patient contributions, in turn, shape team members' view of patients' role in an iterative, virtuous cycle, as patient contributions lead patient and staff team members to view patients as possessing increased, essential knowledge to the work of the team. This process propels an evolution in the patient's social identity, progression through which is marked by an increased sense of patient team member integration, growing respect for their contributions, more responsibilities bestowed upon and

assumed by patient team members, with patient contributions that move from responsive to proactive.

CONCLUSIONS: Patient and staff team member views of a patient's role in innovation teams drive the ways team members interact and the ways patients contribute to team work. Patient evolution requires conscious aim and willingness among all team members to set expectations and support progressive advancement of patients in the overall work of the team

A QUALITATIVE STUDY OF PATIENTS WHO OVERDOSED IN THE CURRENT ENVIRONMENT OF RESTRICTIVE OPIOID PRESCRIBING POLICIES

Shane Mueller¹; Jason M. Glanz^{1, 3}; Steve Koester²; Anh P. Nguyen¹; Ingrid A. Binswanger^{1, 2}. ¹Kaiser Permanente Colorado, Denver, CO; ²University of Colorado Denver, Denver, CO; ³Colorado School of Public Health, Denver, CO. (Control ID #3184382)

BACKGROUND: Faced with the growing opioid overdose epidemic, government agencies, health systems and medical providers have developed and implemented laws and policies to reduce opioid prescribing and expand access to naloxone and substance use disorder treatment. Despite these efforts to reduce overdose risk and improve pain management, overdoses continue to occur at an unprecedented rate. The reasons for this persistently elevated rate remain unclear. We conducted a qualitative study of patients who experienced an overdose and their family members to better understand the factors that led to an overdose in this current environment.

METHODS: We conducted semi-structured interviews with patients from a large integrated care organization in Colorado who experienced an opioid overdose in 2017 or 2018. Patients were identified using ICD codes for overdose and medical charts were reviewed to confirm the overdose. Patients were recruited and asked to invite family members who were present at the time of the overdose to participate in the interview. Interviews explored patients' history of pain, perceived risks and benefits of opioids, circumstances that led to the overdose and actions taken in response to the overdose. A constant comparative method of inductive and deductive analysis was used to code transcribed interviews and generate themes.

RESULTS: We enrolled 9 patients who experienced an opioid overdose, 8 of which involved a pharmaceutical opioid. Five patients were female and mean age was 46.1 years (range 22-65). Three family members of participants also enrolled. We identified 3 themes: The first theme was process failure - It appears as though some policies had limited reach. No patients or family members had picked up naloxone, nor were any patients in treatment for substance use disorder. The second theme was low risk perception - Prior to experiencing the event, patients did not believe they were at increased risk and thought only patients who were using medications to "get high" were at risk. The third theme was increased pain leading to risky behaviors - Patients felt providers reduced opioid dose in response to prescribing policies. These dose reductions led to increased pain and feelings of powerlessness and desperation. To find relief, they took more opioids than prescribed or in combination with other medications and substances, leading to overdose.

CONCLUSIONS: In this qualitative study, we identified 3 major themes related to overdose risk. Our findings suggest that the reach of some preventive interventions, such as naloxone, are limited. Additionally, while these policies have significantly reduced opioid prescribing across the United States, they may also have unintended consequences. Further research should examine the adverse outcomes of these policies at a population level.

A QUALITATIVE STUDY OF THE INFLUENCE OF LOSS AVERSION AND INCREASED SOCIAL PRESSURE IN PHYSICIAN PAY-FOR-PERFORMANCE

John W. Urwin⁴; Shireen E. Matloubieh¹; Judy A. Shea³; Kristen L. Caldarella¹; Matt Walters¹; Akriti Mishra³; Nichia McDowald⁵; Ezekiel J. Emanuel¹; Kevin G. Volpp^{1, 2}; Amol S. Navathe^{1, 2}. ¹Medical Ethics and Health Policy, University of Pennsylvania, Philadelphia, PA; ²CMC VA Medical Center, Philadelphia, PA; ³University of Pennsylvania, Philadelphia, PA; ⁴Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; ⁵Advocate Health Care, Chicago, IL. (Control ID #3184326)

BACKGROUND: Payers are increasingly using behavioral economic principles to design reimbursement programs, despite little evidence regarding the efficacy of these principles on influencing physicians' clinical behaviors. We conducted a qualitative follow-up study to a randomized controlled trial testing how loss aversion and increased social pressure in physician pay-for-performance (P4P) influenced the motivations and behaviors of participating physicians.

METHODS: We interviewed 22 of the 33 physicians who participated in a previously reported randomized controlled trial using a standardized script. The trial included all physicians in an integrated physician network who treated patients with one of five chronic conditions (diabetes, asthma, COPD, CAD, or CHF). Seven participants were in the "active control" arm whose incentive was the same as the year prior; nine were in the loss aversion arm and had the option to withdraw up to 50% of their expected bonus early (averaging \$19,292); and twelve were in the increased social pressure arm and had 50% of their bonus based on group performance, rather than 30%. Transcripts from these interviews were coded by two trained observers and analyzed using nodal analysis with NVivo 11.

RESULTS: The most frequently discussed topics were the financial salience of the interventions (3.6 references per interview), changes in personal motivations (2.3 references per interview), and changes in group dynamics (2.0 references per interview). Participants in the increased social pressure arm demonstrated significantly increased group cohesiveness and individual empowerment that were associated with changes in clinical behavior, including offering additional testing and arranging for closer follow-up. Participants in the loss aversion arm demonstrated little change in their clinical behavior. The ineffectiveness of this arm was attributed to a lack of participation in the voluntary incentive - only two of the eleven physicians withdrew any money - rather than a lack of salience of the principle of loss aversion to physicians necessarily. Barriers to success included clerical burdens of P4P and using outcomes measures rather than process measures for performance bonuses.

CONCLUSIONS: Incorporation of increased social pressure into physician P4P incentive programs can lead to significant changes in physicians' personal motivations, group dynamics, and clinical behaviors. Lack of participation in pre-funded bonuses may indicate limitations to feasibility of using voluntary loss aversion in physician P4P programs.

A QUALITY IMPROVEMENT PROJECT TO INCREASE COMPLIANCE WITH DIABETES MEASURES IN AN ACADEMIC OUTPATIENT SETTING

Jordan Bushman¹; Subhash Edupuganti²; Pradeep Kaminouli^{1, 2}; Alexandra Halalau^{1, 2}. ¹Beaumont Health, Troy, MI; ²Oakland University William Beaumont School of Medicine, Rochester, MI. (Control ID #3165173)

BACKGROUND: Diabetes is one of the most common chronic diseases in the United States, present in nearly 9.4% of the US population.¹ As part of internal medicine residency training, medical residents are often first-line primary care providers in residency

clinics and thus have an important role in providing appropriate diabetes care for these patients. Consequently, American Diabetes Association (ADA) sets forth annual guidelines on preventative measures that can help prevent or delay the onset of more severe complications of diabetes mellitus.² However, previous studies describe suboptimal care amongst residents with regards to preventative care in diabetic patients, including at our own clinic prior to the onset of this study.³ The aim of our project is to improve diabetic care preventative measures, with HbA1c as our primary outcome and other core measures as secondary outcomes, to comply with the ADA recommendations in our resident clinic through the implementation of quality improvement interventions via PDSA (Plan-Do-Study-Act) cycles.

METHODS: Our resident clinic consists of 76 residents working in 8 different teams at Beaumont Hospital - Royal Oak. In November 2016, baseline data was obtained on 538 patients with diabetes, on core ADA measures (HbA1c, foot examinations, lipid panel, etc.). 5 teams developed a quality improvement intervention plan to improve their diabetes care in the clinic and the remaining 3 teams served as controls. Within the next year, PDSA sessions took place every 3 months where teams analyzed their core measure results up to that date and brainstormed strategies to better implement their plans. In November 2017, post-intervention data was collected on the same diabetes core measures.

RESULTS: With HbA1c as our primary outcome, there was paradoxically a slight increase in HbA1c levels in both intervention and control groups post-PDSA cycle (change in HbA1c was +0.09 in intervention, +0.32 in control groups, p = 0.174). With secondary outcomes, the change in outcome measures were as follows: eye examinations (+5% in intervention vs. -7% in control, p<0.01), foot examinations (+13% vs. +5%, p=0.09), lipid panel (+7% vs. -5%, p<0.01), microalbumin (+4% vs. +1%, p=0.03), and HbA1c (+8% vs. +5%, p=0.24).

CONCLUSIONS: While there was not an improvement in HbA1c values, there were significant improvements in the rates of ADA recommended examinations and laboratory tests performed by residents in the intervention groups. One resident team implemented an intervention involving protected half-day blocks for its residents to identify overdue examinations and consequently had the largest improvements in its quality indicators, thus serving as a potential intervention to replicate in future studies. Given our study results, we believe that quality improvement interventions improve preventative care for patients with diabetes in residency clinics.

A RANDOMIZED CONTROLLED TRIAL TO REDUCE JOB BURNOUT USING AN INTER-PROFESSIONAL FACILITATED DISCUSSION GROUP INTERVENTION

Jonathan Ripp¹; Ching See Lau¹; Kyle W. Prochno². ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Sidney Kimmel Medical College, Philadelphia, PA. (Control ID #3184939)

BACKGROUND: Job burnout is common in medical professionals and has been found to correlate with depression, medical errors, productivity, and unprofessional behavior. Based on previous studies which have demonstrated that facilitated discussion reflection sessions may decrease burnout, we chose to examine whether such an intervention might similarly improve measures of well-being using a novel inter-professional participant format.

METHODS: Resident physicians, early-career nurses and social workers from the Mount Sinai Health System in New York, NY were recruited and randomized to either a small-group reflection intervention or a control arm. Intervention participants were invited to participate 1-2 times monthly over 6 months in groups of 6-8 for discussions guided by a curriculum found to be effective in reducing

burnout among practicing physicians. Sessions were facilitated by experts in promoting discussion around work-related challenges between colleagues from different medical professions. Participants in both arms were asked to complete surveys before and after program participation which included measures of burnout, resilience, depression, and job satisfaction. Statistical analysis was performed to identify correlations of burnout and other outcomes at baseline and in relation to participation in the intervention or control arm.

RESULTS: The response rate for the baseline survey was 23/24 (96%) for the control arm and 18/19 (95%) for the intervention arm. 22/24 (92%) control arm participants and 16/19 (84%) intervention arm participants completed the follow-up survey. There were no statistically significant changes in levels of burnout in either the intervention (14/17 (82.4%) pre- v. 13/17 (76.5%) post, p=0.31) or control (17/22 (77.3%) pre- v. 18/22 (81.8%) post-, p=0.56) arms. At baseline, we did identify correlations between burnout and resilience (-0.49, p=0.002) and burnout and meaning in work (-0.30, p=0.04).

CONCLUSIONS: Participation in an inter-professional facilitated discussion group intervention showed no impact on job burnout. As has been previously demonstrated, burnout was found to negatively correlate with baseline resilience and measures of job satisfaction. Our study was limited by its small size and variable participation among colleagues from different professions. Further studies are needed with larger cohorts to better elucidate the benefits of inter-professional facilitated reflection group discussion.

A RANDOMIZED TRIAL OF PEER COMPARISON FEEDBACK TO IMPROVE GUIDELINE-BASED PRIMARY CARE

Amol S. Navathe^{2, 1}; Kevin G. Volpp^{2, 1}; Amelia M. Bond³; Kristin Linn⁴; Kristen L. Caldarella²; Andrea B. Troxel⁵; Jingsan Zhu²; Lin Yang²; Shireen E. Matloubieh²; Elizabeth E. Drye⁶; Susannah Bernheim⁶; Emily Oshima Lee⁷; Mark Mugishti⁷; Kim Takata⁷; Justin Yoshimoto⁷; Isaac Yuen⁷; Sheryl Okamura⁷; Michael Stollar⁷; Jeffrey Tom⁷; Michael Gold⁷; Ezekiel J. Emanuel^{2, 1}CMC VA Medical Center, Philadelphia, PA; ²Medical Ethics and Health Policy, University of Pennsylvania, Philadelphia, PA; ³Healthcare Policy and Research, Weill Cornell Medical College, New York, NY; ⁴Biostatistics, Epidemiology and Informatics, University of Pennsylvania, Philadelphia, PA; ⁵New York University School of Medicine, New York, NY; ⁶Yale University School of Medicine, New Haven, CT; ⁷Hawaii Medical Service Association, Honolulu, HI. (Control ID #3182764)

BACKGROUND: Peer comparisons, providing feedback on clinician performance relative to peers, have been tested successfully in narrow settings such as increasing guideline-based antibiotic and opioid prescribing. However, there are no studies evaluating the effectiveness of peer comparisons on broader quality measures in the setting of alternative payment models.

METHODS: We conducted a cluster randomized trial with the Blue Cross Blue Shield of Hawaii to examine the impact of providing peer comparison feedback to its primary care practitioners (PCPs) on the quality of care. This study included patients of 86 PCPs randomized to receiving peer comparisons plus individual feedback (intervention group) versus individual feedback alone (control group). Feedback was provided on quality, cost, and utilization performance. All PCPs were also simultaneously moved to a new population-based primary care payment system. The primary outcome was the probability of achieving national benchmark thresholds on thirteen primary care focused quality metrics that included preventative and chronic disease measures. We analyzed the primary outcome using a generalized linear model, adjusting for patient characteristics, PCP characteristics, baseline proportion of measures achieved by the patient, and a quality measure fixed-effect, clustering standard errors at the PCP.

RESULTS: The RCT included 27,930 patients and 31 PCPs in the control group and 46,694 patients and 55 PCPs in the intervention group. Patients nor PCPs exhibited large differences across groups, with small differences in demographics and panel size, respectively. In primary analysis, the patients in the peer comparisons intervention group experienced a 2.4 percentage point (pp) increase in the probability of achieving an eligible quality measure (95% CI 0.3 pp to 4.6 pp, p=0.03). Secondary analysis of individual measures indicated that Breast Cancer Screening (3.9 pp, 95% CI 0.2 to 6.0 pp, p<0.001), Cervical Cancer Screening (2.4 pp, 95% CI 0.01 to 4.8 pp, p=0.05), Colorectal Cancer Screening (2.8 pp, 95% CI 0.3 to 5.2 pp, p=0.03), Diabetes Care - Eye Exam (5.6 pp, 95% CI 1.6 to 9.5 pp, p = 0.006), Diabetes Care - Medical Attention for Nephropathy (2.5 pp, 95% CI 0.4 to 4.6 pp, p=0.02) and Review of Chronic Conditions (4.9 pp, 95% CI 0.0 to 9.8 pp, p=0.05) likely accounted for the increased overall quality score. Other measures demonstrated trends toward differential improvement, but associations were not significant. Cost and utilization did not demonstrate differences between arms.

CONCLUSIONS: A peer comparisons intervention that displayed quality information in a real-time dashboard in the setting of a broad primary care payment system change improved quality scores by over 2 percentage points. This highlights the ability of peer comparisons to influence clinician practice in broad endpoints and is reassuring in light of new payment programs that have begun sharing comparative feedback.

A RETROSPECTIVE REVIEW OF EPIC MYCHART UTILIZATION AMONGST PAYER CLASSES WITHIN A FEDERALLY QUALIFIED HEALTH CENTER NETWORK IN BROOKLYN NEW YORK

Isaac Dapkins²; Rhett Pilao¹; Neil A. Pasco¹. ¹NYU Langone Health, New York, NY; ²NYU, Brooklyn, NY. (Control ID #3185686)

BACKGROUND: The Hitech Act of 2009 led to Federal funding on EHR incentives such as Advancing Care Information within MIPS and Meaningful Use. EPIC currently has a *MyChart* application which allows a patient to interface with their medical records and provider. The Family Health Centers (FHC) at NYU Langone is a network of 8 Federally Qualified Health Centers (FQHC) located in Brooklyn New York. The primary service area has a large immigrant population with 47% of the population reported as being foreign born, and a diverse payor mix with 12% of patients being self-pay/uninsured.

METHODS: Retrospective analysis was performed regarding 78,168 unique patients seen within the Family Health Center Network from January 2018 to December 3rd, 2018. Patient were identified by payor class and by utilization of *MyChart*. Given the diversity of healthcare plans afforded within New York State, payor classes were grouped into 7 broad categories: Medicaid/ Managed Medicaid, commercial, Medicare/ Managed Medicare, self-pay, no insurance, Child Health Plus and Medicaid Expansion (Affordable Care Act). Patient *MyChart* data abstraction within the EPIC Clarity database included whether the patient was enrolled and when the last date of activity occurred. Enrollment with activity versus enrollment without activity within the last calendar year was used to gauge whether the patient would be considered an active subject in this retrospective review.

RESULTS: Regarding percentage of patient enrolled in *MyChart*, the patient population most likely to enroll was found to be those who have commercial health plans at 41%, with Medicaid expansion plans at 37%, followed by Medicaid tied with self-pay coverage (23%) and Medicare at 18%. Utilization tells a different story with the highest utilizers found in the Medicare enrollees at 79%, followed by Medicaid expansion at 78%, then commercial plans at 77%. The next tier of active users was found to be no coverage (67%), self-pay (66%) and Medicaid (61%). Retrospective review with enrollment data was somewhat expected; high enrollment in patients with commercial plans and lower enrollment amongst Medicare beneficiaries. What was surprising was the utilization/activity data

revealed an entirely different picture. Activity usage reflected two tiers. Patients who have Medicare utilize the application as much as patients who have commercial plans and Medicaid expansion. Despite connotations on patients who are self-pay or who have no coverage at all, these patients still use the application, with greater than 50% of those enrolled, actively using *MyChart* within the last calendar year.

CONCLUSIONS: As medical care becomes more immersed in web-based technologies, attention and opportunities exist for patients who traditionally were viewed as not having access nor inclination to use such technologies. Continued efforts should be maintained regarding enrollment regardless of the payor class or age.

A SCOPING LITERATURE REVIEW OF PHYSICIAN SUICIDE

Sima Pendharkar¹; Tiffany I. Leung^{2,2}; Chwen-Yuen A. Chen^{3,3}. ¹Mount Sinai Health System, Brooklyn, NY; ²Maastricht University, Maastricht, Netherlands; ³Stanford University, Palo Alto, CA. (Control ID #3142595)

BACKGROUND: Physician suicide is a global issue with significant consequences for workforce sustainability and for public health and disproportionately affects women physicians [1]. A clearer understanding of physician suicide is needed. A literature review would enable community learning towards preventing physician suicidal behaviors. The aim of this scoping review was to map the landscape of published research and perspectives on physician suicide.

METHODS: This scoping review was conducted following the Arksey and O'Malley framework as expanded upon and outlined within the Joanna Briggs Institute Reviewers' Manual. A broad research question was crafted by our team. The protocol was registered with PROSPERO. For the purposes of this review, the research question was broadly designed for gathering and analyzing all citations in scholarly journals which mentioned physician suicide specifically. The initial searches were executed on August 21, 2017 in Ovid MEDLINE, and October 11, 2017 in Ovid PsycINFO. Team members contributed seed articles which were analyzed by the librarian coauthor. Search terms and databases were selected and tested before the search strategy underwent a peer review process with two additional medical librarians. A subsequent sweep of the citation index, Scopus, was conducted on April 28, 2018. Inclusion criteria were English-language journal publications, including opinion/perspective publications, that focus primarily on physician suicide. Exclusion criteria were non-English or media publications. Data extraction was performed and topic annotations were applied to citations.

RESULTS: Query results totaled 1,596 citations; 348 studies passed the full-text review round. The earliest article is an editorial from 1903; more than 60% of articles were published in 2000 or later. There were 142 opinion articles (40.8%). Of the remaining 206 articles, a variety of study designs were used; 84 used a cross-sectional study design, which was most common. Authors from 37 countries were represented, although authors from the U.S. (n=51) are the largest subset. Only 13 publications described interventions. Unexpected subpopulations described included immigrant physicians, physician pilots, and physicians who experienced war either as victims (e.g. Holocaust survivors who were physicians) or as wartime medics. One investigator studied the interpersonal psychological theory of suicidal behavior in physicians, which posits three necessary and sufficient precursors to death by suicide: (1) thwarted belongingness, (2) perceived burdensomeness, and (3) acquired capability.

CONCLUSIONS: Most journal articles about physician suicide were published recently – a promising reflection of growing awareness. Limitations include excluding non-English language articles, interventions that mitigate only burnout, and other media. Further research and advocacy is needed in support of interventions specifically targeted for physician suicide prevention. [1] Leung et al. SGIM Forum 41 (9): 4-5, 14

A SINGLE CENTRE RETROSPECTIVE STUDY COMPARING POST-OPERATIVE OPIOID PRESCRIBING PRACTICES BETWEEN CAESAREAN SECTIONS AND OPEN GENERAL SURGERY PROCEDURES

Tanya Girard¹; Emily G. McDonald¹; Natalie Dayan¹; Miriam Harris¹; Amira El-Messidi²; Todd C. Lee¹; Sophie Gosselin²; David Fleiszer²; Andre Bonnici²; Eric Villeneuve². ¹McGill University, Montréal, QC, Canada; ²McGill University, Montreal, QC, Canada. (Control ID #3181947)

BACKGROUND: Physician prescribing practices are contributing to the North America opioid crisis. Identifying practice variability may be an important step towards addressing the problem. The objectives of this study were to compare postoperative opioid prescribing practices between selected open abdominal and pelvic surgeries and highlight variations in practice.

METHODS: A retrospective cohort study of 927 patients who underwent a caesarean section (CS) or one of four open general surgery (GS) procedures performed between January and November 2017 at a university health centre in Montréal, Canada. Open GS procedures included appendectomy, cholecystectomy, hernia repair, and laparotomy for lysis of intra-abdominal adhesions. Post-operative opioids in daily morphine equivalent doses (MED) in hospital and at discharge were compared between CS and open GS procedures with similar expected post-operative pain and length of admission. Factors associated with the odds of receiving more than 50mg MED daily at discharge were explored via logistic regression.

RESULTS: 927 patients were included; 689 women underwent a CS and 238 (180 men and 58 women) underwent an open GS procedure. Patients undergoing CS were more likely to receive higher doses of daily post-operative opioids in the hospital than GS patients and the difference was more pronounced for men than women (80mg MED (IQR 80-80) for CS vs 15 mg MED (IQR 0-60) for GS men and 45mg MED (IQR 0-90) for GS women; p<0.001). At discharge, patients who underwent a CS received lower median doses of opioids than GS patients (20mg MDE (IQR 20-20) vs 45mg MDE (IQR 40-60); p<0.001). The odds ratio of exceeding the Centre for Disease Control's (CDC) recommended daily maximum of 50mg of MED was 19.8 (CI 6.2-63.1) for GS men and 19.3 (CI 5.4-68.1) for GS women, with CS as the reference group.

CONCLUSIONS: In a study of post-operative opioid prescribing practices, when compared to general surgeons, obstetricians prescribed lower doses of opioids at hospital discharge and were less likely to exceed the CDC's safe dosing recommendations. Prescribing variability and discordance with recommended safe doses could be minimized by using pre-printed discharge prescriptions for given procedures.

A STUDY OF STANDARD DEVIATION OF NEXT AVAILABLE APPOINTMENTS

Sumeet Brar²; Michael Hopkins¹; David Margolius¹. ¹The MetroHealth System, Cleveland, OH; ²Case Western Reserve University, Cleveland, OH. (Control ID #3177863)

BACKGROUND: Days until third next available appointment is a metric that describes backlog for appointments by counting the number of days until the third next available appointment on a clinician's schedule. The metric is widely used by health care systems as a measure of access to care. Third next is considered a more reliable metric because last-minute cancellations might distort the days until the first or second next. We tested this assumption by comparing the variability over time of days until first, second, third, and fourth next available appointments.

METHODS: We collected four variables - the number of days until first, second, third, and fourth next available appointments - for clinicians over a 20-week period, in weekly increments. Clinicians were included if we had complete appointment data for all values. For clinicians who worked

in more than one location, each location schedule was counted separately as the values were unique. Clinicians were physicians and advanced practice providers in all specialties, dietitians, audiologists, psychologists, and optometrists. All clinicians were employed by a multi-site tertiary health care system. We calculated the standard deviation from the mean for each variable for each clinician across all weekly values. We then averaged standard deviations, so that the outcome was an average standard deviation of days until first next, an average standard deviation of days until second next, and so on. We used a one-way ANOVA to compare the effect of counting out first, second, third, or fourth next available appointments on the standard deviation of the variables. We conducted post hoc analyses with the Tukey test.

RESULTS: Our study sample included 421 clinicians working from 611 schedules. The mean first, second, third, and fourth next available appointment across all dates and clinician schedules was 20, 24, 26, and 27 respectively. The mean standard deviation for each variable beginning with first next available was 10.7, 9.4, 9.0, and 8.8 days. An analysis of variance showed that the effect of measuring days until sequential available appointments on standard deviation was significant, $F(3,2440)=11.66$, $p<.01$. Post hoc comparisons with the Tukey test showed that standard deviations of first next available appointments differed significantly from standard deviations of each of the other metrics ($p<.01$), but mean standard deviations from second, third, and fourth next available did not significantly differ from each other.

CONCLUSIONS: Days until first next available appointment is a less consistent measure from week to week than days until second, third, or fourth next available appointment. This study is the first to add evidence that second next is a more reliable metric than first next, but we found no statistically significant difference between the reliability of second and third next. Health care systems may choose to use days until second next available appointment as a more practical access metric.

A SURVEY OF ATTITUDES AROUND OPIOID USE DISORDER AND PERCEIVED BARRIERS TO PROVIDING BUPRENORPHINE MAINTENANCE TREATMENT AMONG OUTPATIENT PRIMARY CARE PROVIDERS IN AN URBAN ACADEMIC MEDICAL SETTING

Monique A. Tello¹; Sarah E. Wakeman¹; Stuart R. Lipsitz²; Lipika Samal². ¹Massachusetts General Hospital, Charlestown, MA; ²Harvard Medical School, Boston, MA. (Control ID #3184407)

BACKGROUND: The US is experiencing an epidemic of opioid use disorder (OUD), which can be effectively treated with buprenorphine in the outpatient primary care setting. Primary care providers (PCPs) must complete 8 hours of training and apply for a waiver to prescribe buprenorphine, but only a fraction have done so, and not all prescribe. Our goal was to identify barriers that could be addressed through educational or logistical interventions.

METHODS: A 41-item self-report survey was created after a review of the literature and administered anonymously through the online service SurveyMonkey (San Mateo, CA). PCPs were asked to self-identify as waivered or non-waivered. PCPs were then queried about the magnitude of the issue in their geographic area and their practice, personal impact of the opioid epidemic, perceived effectiveness of OUD treatment modalities, and potential logistical barriers to training and prescribing buprenorphine (depending on their waiver status). All PCPs (physicians, physician assistants, and nurse practitioners) at two academic medical centers were asked to complete the survey. Results were characterized using descriptive statistics and compared across non-waivered and waivered respondents using logistic regression.

RESULTS: Responses were received from 100 PCPs who were predominantly MDs (93%) and female (72%); 69% had not completed buprenorphine waiver training; 31% had (and 67% of those were actively prescribing). 99% of PCPs said that OUD was an issue in their geographic

area, 94% reported seeing patients with OUD, and 18% reported that they had been personally impacted by the opioid epidemic. 84% of PCPs rated buprenorphine maintenance as moderately or very effective, the highest ranked of six OUD treatment options (including 12-step programs, outpatient counseling, inpatient rehabilitation, methadone maintenance, and extended-release naltrexone). Non-waivered PCPs were significantly more likely than waivered PCPs to say that they did not see enough patients with OUD to change their practice (OR 0.267, $p=0.005$) and were also more likely to express concern about allowing patients with OUD into their practice (OR 0.348, $p=0.020$). There were no other significant differences between those two groups (safety, moral acceptability, or diversion risk of buprenorphine, time, financial support, peer mentoring, psychosocial support staff, potential legal issues).

CONCLUSIONS: Surprisingly, non-waived PCPs cite too few OUD patients to justify training, but the vast majority of them report having OUD patients, feel the opioid epidemic is an issue in their geographic area, and rate buprenorphine/haloxone maintenance as the most effective treatment option for OUD. Non-waived PCPs were also significantly concerned about allowing patients with OUD into their practice. There were no other differences, which suggests attitudinal barriers (i.e. stigma) as the most appropriate target for intervention.

A SYSTEMATIC REVIEW OF THE CAUSES, IMPACT AND RESPONSE TO MORAL DISTRESS AMONG MEDICAL STUDENTS

Susan B. Glick; Jacob Schulman; Max Harris; Daniel Pohlman. Rush Medical College, Chicago, IL. (Control ID #3186130)

BACKGROUND: Moral distress occurs when one is aware of the moral and ethical course of action, yet is unable to perform it. Lack of resources and futile care are some of the many reported causes of moral distress among healthcare professionals, and may result in frustration, anger, a sense of powerlessness, job dissatisfaction and intent to leave the profession. These symptoms are strikingly similar to those of burnout and may be confused with it. Medical students may disproportionately experience moral distress, as they are well trained in the ideals to which the profession aspires, yet wield little power in the health care system. To prevent, diagnose and treat moral distress among medical students requires an understanding of the causes and impact of moral distress, as well as the response to it at the personal, professional and institutional levels.

METHODS: With the assistance of a medical librarian, we conducted a systematic review of the English language literature to assess studies that described moral distress among medical students. We searched OVID, CINAHL, PsycINFO, and ERIC from their inception through October 2018. We searched the reference sections of relevant review articles as well as all included studies for additional manuscripts. Eligible studies had to represent an original study; present data about the causes, impact, or response to moral distress; measure and report outcomes in medical students; and report findings in English. Titles and abstracts were reviewed. Articles not recommended for exclusion were reviewed in full. Following full text review, those articles that did not meet all four inclusion criteria were excluded.

RESULTS: The search yielded 63 articles. Following title, abstract and full text review, 6 studies were included. Five addressed situations that result in moral distress; two addressed its impact. No studies addressed the response to moral distress. Due to data heterogeneity, narrative synthesis was performed. Studies differed in their conclusions about which situations resulted in the greatest moral distress, including those with immediate potential to cause harm; covert, status-related and verbal abuse; communication issues, intra-team conflicts, resource allocation, and access to care; and experiences with geriatric patients. Role modeling was inversely correlated with student distress, as was action-taking. One study found repeated exposure to moral distress can result in either emotional desensitization or in worsening distress. Studies differed in their conclusions about whether moral distress disproportionately affected women or men.

CONCLUSIONS: Little is known about the situations that result in moral distress among medical students and its impact. The literature is silent on the response to medical students' moral distress. Deepening our understanding of the causes, impact and response to moral distress among medical students is imperative to promote student wellness.

A TRANSFORMATIVE APPROACH: MOTIVATIONAL INTERVIEWING CURRICULUM IMPROVES PATIENTS' HEALTHY BEHAVIORS WHILE ENHANCING LEARNING

Chavon Onumah¹; Mihir Patel²; Matthew Mintz¹; Namarik Alenezy³. ¹George Washington University, Washington, DC; ²George Washington University, Washington, MD; ³George Washington University SMHS, Washington, DC. (Control ID #3184308)

BACKGROUND: Modifiable risk behaviors account for a considerable amount of morbidity and mortality. Motivational interviewing is a patient-centered method of *guiding* patients to modify health behaviors that can help address health disparities. As few as one MI session may be effective in enhancing readiness to change and promoting action towards change. MI curricula, is being implemented in medical training, however, data regarding curricular outcomes is limited to knowledge and confidence gained by students through the use of standardized patients and role-play exercises. Data is lacking on the student experience with MI curricula involving live patients and patient outcomes with one student-led MI session.

METHODS: Using Kolb's Experiential Learning Cycle as a Model, a 4-part MI curriculum, "Promoting Healthy Behaviors," was implemented in our longitudinal primary care clerkship to enhance learning in motivational interviewing. The curriculum includes self-directed learning, small-group exercises, standardized patient practice, AND a real-life clinical intervention (medication adherence, lifestyle modification, or substance cessation) with patient follow-up and reflection. The curricular initiative was implemented as a core requirement for all clinical clerkship students (N=155). Students completed anonymous surveys regarding their experience with the project and their respective patient's goal progress at the time of follow-up. Data was analyzed via quantitative and qualitative methods. Three faculty members coded qualitative responses independently through open coding. Disagreement was resolved by discussion and data recoded by a final coding scheme. The authors discussed the coded data to arrive at a final set of themes.

RESULTS: 78% of patients reported progress towards their self-directed health behavioral change goal established in the student-led MI encounter at 4 to 6 weeks post-encounter. From student reflections, the following themes across the knowledge, skills, and attitudes learning domains emerged: *Meeting patients "where they are at" on the Stages of Change scale is key in promoting change. Behavioral change is difficult and takes considerable support and follow-up. Incremental changes, tapping into internal motivation, and addressing barriers aid in success. Motivational interviewing is an impactful way to promote healthy behaviors and important skill to learn.*

CONCLUSIONS: The Promoting Healthy Behaviors project is an effective method of enhancing multi-dimensional medical student learning in motivational interviewing and engaging patients in behavior change and health promotion. A clinical intervention with follow-up helped students appreciate their potential impact, recognize the difficulties patients experience in moving towards behavioral change, and provided "immediate applicability" for skills learned through the in-class and standardized patient exercises. The high rate of patients reporting successful goal progress is encouraging, however, more outcome data is warranted.

ACCEPTABILITY OF SOCIAL RISK SCREENING TO PATIENTS AND CAREGIVERS

Emilia De Marchis¹; Danielle Hessler¹; Nancy E. Adler¹; Elena Byhoff²; Alicia Cohen³; Kelly M. Doran⁴; Stephanie Ettinger de Cuba⁵; Eric Fleegler⁶; Nicholas Gavin¹⁰; Amy G. Huebschmann⁷; Stacy T. Lindau⁸; Maria C. Raven¹; Elizabeth L. Tung⁸; Caroline Fichtenberg¹; Susan Jepson¹¹; Wendy Johnson¹²; Cara C. Lewis¹³; Eduardo Ochoa¹⁴; Ardis L. Olson¹⁵; Aric Prather¹; Megan Sandel⁵; Richard Sheward¹⁶; Laura M. Gottlieb⁹. ¹University of California, San Francisco, San Francisco, CA; ²Tufts Medical Center, Boston, MA; ³University of Michigan, Ann Arbor VA, Ann Arbor, MI; ⁴NYU School of Medicine, New York, NY; ⁵Boston University School of Medicine, Boston, MA; ⁶Boston Children's Hospital, Boston, MA; ⁷University of Colorado School of Medicine, Aurora, CO; ⁸University of Chicago, Chicago, IL; ⁹UCSF, San Francisco, CA; ¹⁰Columbia University Vagelos College of Physicians and Surgeons, New York, NY; ¹¹Hennepin Healthcare, Minneapolis, MN; ¹²La Familia Medical Center, Santa Fe, NM; ¹³Kaiser Permanente Washington Health Research Institute, Seattle, WA; ¹⁴University of Arkansas, Little Rock, AR; ¹⁵Dartmouth Medical School, Hanover, NH; ¹⁶Boston Medical Center, Boston, MA. (Control ID #3141279)

BACKGROUND: Despite the health care sector's growing interest in systematic collection of social risk data, little is known about patient acceptability of health care-based social risk screening. Acceptability to patients and caregivers has implications for adoption, utility and sustainability. We aimed to explore acceptability of the Center for Medicare and Medicaid Innovation's (CMMI) social risk screening tool, which covers 5 actionable social domains: food, housing, utilities, and transportation security, and personal safety.

METHODS: Cross-sectional analysis of patients or caregivers of pediatric patients recruited from 6 primary care clinics (PCCs) and 4 emergency departments (EDs). Participants completed a tablet-based survey that included the CMMI social risk tool and questions related to both acceptability of social screening and predictors of acceptability. The primary acceptability measure was perceived appropriateness of screening in health care settings; a secondary outcome was comfort with including social risk data in electronic health records (EHRs). Multilevel mixed-effects logistic regressions were used to evaluate acceptability measures, clustering by site.

RESULTS: 969 patients/caregivers completed the survey; 952 (98%) answered survey questions about acceptability. 72% of participants screened positive for at least 1 of 5 social risks. 80% of respondents reported screening was very or somewhat appropriate; 7% reported screening was very or somewhat inappropriate. 65% of participants reported being completely or somewhat comfortable with social risk data being included in EHRs; 18% reported being completely or somewhat uncomfortable. In the primary multivariable model, participants reporting higher acceptability of social risk screening had higher odds of previous social risk screening in a health care setting (aOR 1.80 [95% CI 1.31-2.47]); not endorsing prior discrimination in a health care setting (aOR 1.45 [95% CI 1.07-1.97]); being from a safety-net setting (aOR 1.85 [95% CI 1.11-3.10]); and being recruited in a PCC (aOR 2.10 [95% CI 1.01-4.32]). Participants who were more comfortable with including social risk data in EHRs had higher odds of previous social risk screening in a health care setting (aOR 1.56 [95% CI 1.17 to 2.09]). There were no associations between specific social risk domains or cumulative number of social risks with either measure of acceptability. No additional respondent-level characteristics were associated with acceptability.

CONCLUSIONS: Across PCC and ED settings, a majority of respondents found social risk screening acceptable. Acceptability levels did not differ across individual health care settings or level of social risks, though we identified some potentially modifiable factors associated with

acceptability. High rates of acceptability support health care-based social screening implementation efforts, although future research should explore how to improve acceptability in specific patient populations and acceptability of EHR integration.

ACCESS TO TREATMENT FOR DRUG USE DISORDER AT U.S. HEALTH CENTERS: A NATIONAL STUDY

Benjamin I. Bearnot¹; Danielle R. Fine²; Nancy A. Rigotti¹; Travis P. Baggett¹. ¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital, Brookline, MA. (Control ID #3185426)

BACKGROUND: Drug use disorder (DUD) is a growing public health concern in the US, particularly among medically-underserved and low-income populations. Treatment rates for DUD remain low despite the existence of evidence-based behavioral and pharmacologic treatments. Little is known about the barriers to accessing DUD treatment at federally-funded US health centers, which provide care to nearly 30 million vulnerable individuals annually. The aim of this study was to examine the continuum of DUD care, location of treatment delivery, and barriers to receiving treatment at Health Resources and Services Administration (HRSA) funded health centers.

METHODS: We analyzed data from adult respondents to the 2014 Health Center Patient Survey, a cross-sectional, nationally representative, in-person survey of HRSA health center patients conducted between 9/2014 and 4/2015 with a 3-stage sampling design. The main measure was self-reported symptoms of DUD, assessed using the WHO ASSIST questionnaire. Individuals with 2 symptoms were defined as having a diagnosis of DUD. We examined responses to a series of questions regarding receipt of DUD care, the location of this care, and the primary reason individuals were unable to access treatment. We conducted analyses in SAS using strata, cluster, and weight variables to account for complex sampling design. Percentages are weighted to reflect health center patients nationally. Rao-Scott 2 tests and t-tests were used to compare proportions and means, respectively, with a 2-sided P value <0.05 for significance.

RESULTS: Among 5,547 participants, 374 (4.5%) had current evidence of DUD. 293 individuals (85.3%) had a single DUD, while 81 (14.7%) had a DUD of 2 or more substances. Among respondents with DUD, the most commonly used substances were cannabis (74.8%), sedatives (21.1%), cocaine (19.1%), stimulants (15.5%) and opioids (10.6%). 11.6% had ever used injection drugs. 49.7% reported discussing drug use with a health professional, 35.7% reported wanting or needing treatment, and 28.3% reported receiving treatment for DUD. Among 102 individuals who reported receiving DUD treatment, 37% received treatment that was delivered at a HRSA health center, while 63% sought treatment elsewhere. Among 41 respondents who wanted but did not receive DUD treatment, the most commonly reported reasons for not obtaining treatment were stigma, skepticism about treatment, logistical and financial barriers.

CONCLUSIONS: Symptoms of DUD were more common in this nationally representative study of community health center attendees than in other national surveys, although there are notable differences in methodology. Only half of individuals with DUD discussed their drug use with a health professional, and even fewer reported wanting, needing, or receiving treatment. Marked losses across the continuum of DUD care highlight the considerable barriers to routinely identifying, referring, and linking individuals to effective addiction care at U.S. health centers.

ACUTE HEART FAILURE EXACERBATION AND INFLUENZA INFECTION

Nicholas Daering; Lindsey Aurora; Lucas Maahs; Zachary Bauer; Ahmed Dakka; Leika Raychouni. Henry Ford Hospital, Detroit, MI. (Control ID #3176759)

BACKGROUND: Influenza infection causes 3-5 million cases of severe illness annually and has been linked to exacerbations of congestive heart failure (CHF) as well as myocarditis. Patients with diagnosed CHF appear to have an increased risk of hospitalization during influenza season, but a relationship between serologically diagnosed influenza infection and acute heart failure (AHF) exacerbations has not been studied.

METHODS: This was a retrospective chart review studying patients with a diagnosis of CHF between April and October 2016 with specific focus on those presenting with AHF exacerbations until 2018. Descriptive data was collected regarding patient demographics, total number and dates of encounters, length of stay, presenting laboratory values, influenza testing results, intensive care admission, and outcomes including mortality. This data was divided based on influenza testing status and univariate analysis was applied to capture any association of peak influenza infection with peak AHF encounters, correlation of influenza infection with length of stay, and correlation of influenza infection with patient demographics. Descriptive statistics were gathered on all variables of interest. Statistical significance was set at p-value <0.05. All analyses were performed using SAS 9.4.

RESULTS: Out of 1880 patients with a diagnosis of AHF exacerbation, there were two defined groups: influenza positive (n=28), and influenza negative/not tested (n=1852). There was no significance noted amongst the rate of heart failure exacerbations between these two groups (Table 1, p-value 0.134). Out of all variables analyzed, only two demonstrated statistical significance between influenza positive and influenza negative/not tested groups. Diagnosis of pulmonary hypertension (p-value 0.013) and coronary artery disease (p = 0.031) was more likely in influenza positive patients. No statistically significant correlation was found for the primary endpoint of influenza positivity with acute heart failure exacerbation.

CONCLUSIONS: This data comprised a significant portion of patients with AHF exacerbations with negative influenza tests or those that were not tested. This allows us to deduce that perhaps a larger cohort of patients may be required to determine if there is true statistical significance of additional variables and endpoints. These results also indicate a need for higher clinical suspicion of influenza infection in patients with heart disease, particularly coronary artery disease and pulmonary hypertension. Future studies may also focus on the effect of influenza treatment on hospital outcomes for cardiac patients.

ADDING SOCIAL AND FUNCTIONAL DETERMINANTS OF HEALTH IMPROVES READMISSION RISK PREDICTION IN URBAN UNDERSERVED ADULTS HOSPITALIZED FOR ACUTE MYOCARDIAL INFARCTION

Oanh K. Nguyen^{1, 2}; Anil N. Makam^{1, 2}; Christopher Clark³; Sameh Saleh¹; Sandeep R. Das⁴; Ethan Halm⁵. ¹UT Southwestern Medical Center, Dallas, TX; ²University of California, San Francisco, San Francisco, CA; ³Parkland Health & Hospital System, Dallas, TX; ⁴University of Texas Southwestern Med Ctr, Dallas, TX; ⁵Univ of TX Southwestern Med Ctr, Dallas, TX. (Control ID #3181967)

BACKGROUND: Although social and functional determinants of health (SFDoh) are increasingly recognized to contribute to increased 30-day readmission risk for cardiovascular illnesses, most health systems lack individual-level data to enable individual risk stratification and targeted interventions to address these needs. We sought to determine whether electronic health record (EHR) data in SFDoh domains collected as a part of routine inpatient care from a safety-net hospital could be used to enhance prediction of 30-day readmissions beyond traditional clinical risk factors alone among underserved adults hospitalized with acute myocardial infarction (AMI).

METHODS: We used Epic EHR data on AMI hospitalizations from 2014-2017 in an urban safety-net hospital in Dallas to predict non-elective 30-day readmissions to any of 75 hospitals in north Texas, using a

regional all-payer hospitalization database.. We started with the AMI READMITS score, our previously validated model consisting of 7 clinical risk factors. Next, we derived and validated an enhanced model incorporating SFDoh predictors. EHR data for candidate SFDoh predictors included structured, semi-structured, and short free-text fields from demographics, encounter types, note types, and case manager, social worker, and nursing inpatient flowsheets. We selected novel predictors using stepwise backward selection with a threshold of $p < 0.20$, forcing in the composite AMI READMITS score. We conducted sensitivity analyses using forward selection, lasso regression, and random forest which resulted in similar models. We internally validated our final model using 5-fold cross-validation and compared model performance to the AMI READMITS score.

RESULTS: Of 1,071 hospitalizations, 154 (14.5%) were readmitted within 30 days. In addition to the composite AMI READMITS score, our final model included 9 SFDoh risk factors, including neighborhood poverty (aOR 1.39, 95% CI 0.91-2.14), address change in the past year (aOR 1.53, 95% CI 0.96-2.46), any opioid use in the past year (aOR 2.35, 95% CI 1.36-4.05), history of durable medical equipment use in the past year (aOR 1.70, 95% CI 1.02-2.82), and ADL impairments in feeding, bathing, and toileting in the past year (aOR 1.81 for all three impairments, 95% CI 0.99-3.29). The AMI READMITS+SFDoh model had better discrimination than AMI READMITS alone (optimism-corrected C-statistic 0.69 vs 0.62, $p < 0.001$), was able to predict a broader range of probabilities for readmission risk (3.6-72.7% vs. 8.2-37.2%), and improved net reclassification (categorical NRI of highest 2 risk quintiles vs. lowest 3 of 0.09, 95% CI 0.00-0.18).

CONCLUSIONS: Incorporating existing EHR data on social and functional determinants of health improved readmission risk prediction after an AMI hospitalization in an urban underserved population.

ADDRESSING LATENT TUBERCULOSIS INFECTION TESTING AND TREATMENT IN ORANGE COUNTY, CALIFORNIA: BASELINE ASSESSMENT AT A LOCAL HEALTH CENTER

Fayette K. Nguyen Truax¹; Setie Asfaha²; Tessa Mochizuki²; Setie Asfaha²; Julie Low³; Michael Carson³; Duc Nguyen⁴. ¹Loma Linda University, Wildomar, CA; ²California Department of Public Health, Richmond, CA; ³County of Orange Health Care Agency, Santa Ana, CA; ⁴Nhan Hoa Health Center, Garden Grove, CA. (Control ID #3185388)

BACKGROUND: Of the 3.2 million individuals in Orange County, California, an estimated 240,646 (7.5%) are Vietnamese. Of these, 153,329 are non-U.S.-born individuals. In 2017, of the TB cases in Orange County, 89% were among non-U.S.-born individuals, of whom 42% were born in Vietnam. In Orange County, the estimated percentage of non-U.S.-born individuals with latent TB infection (LTBI) is 17.3% as compared to 1.6% in U.S.-born individuals. A key strategy to eliminate TB is to increase LTBI testing and treatment in non-U.S.-born populations at community clinic settings. We conducted a baseline assessment of barriers, facilitators and current practices surrounding LTBI care to identify opportunities for improvement.

METHODS: A local community clinic serving primarily Vietnamese individuals was chosen. To identify barriers and facilitators to LTBI care, Likert-type scale surveys were given to providers, 1(strongly agree) to 7(strongly disagree). To understand current LTBI practices, we abstracted charts for patients who had a TB test in 2017 and a subset of charts for patients who had a physical exam during August 1-14, 2017. Data were entered into REDCap and analyzed using SAS.

RESULTS: Eight of 10 (80%) providers completed the survey. All respondents agreed that testing and treating patients born in countries with an elevated TB rate for LTBI will improve their patients' long-term health. Only four (50%) providers were comfortable with LTBI drug regimens other than 9 months of isoniazid therapy. Four (50%) providers

were confident in their ability to convince patients to accept treatment. Three (38%) providers did not feel they customarily had enough time to assess patients for LTBI. A query of the electronic health record showed a total of 270 patients had a tuberculin skin test (TST) ordered in 2017. Of these, 220 (82%) had results documented: 42 (19%) were positive, of whom 40 (95%) had chest x-rays ordered, all of which were negative. Of the 40, 3 (8%) started preventive treatment, but no treatment completion was documented. Of the 124 patients who had a physical exam during August 2017, the median age was 54 (range 5-72) and 110 (89%) were Asian. Of the 110, 102 (93%) spoke Vietnamese as their primary language, and of those, 97 (95%) had no prior treatment documented. Of those with no prior treatment, 8 (8%) were tested for LTBI; of the 8, 3 (38%) had positive results; 2 had chest x-rays completed; 2 started treatment and 1 had treatment completion documented.

CONCLUSIONS: Our community clinic serving a high-risk population could improve on screening and treating patients for LTBI. Following these results, LTBI training for providers and ancillary staff were provided. Further, a new process for documenting TB risk factors has also been implemented. Further barriers should continue to be examined and addressed through training and provision of educational materials from local public health agencies. An ongoing partnership among key partners is encouraged to foster best practices.

ADDRESSING OVERTREATMENT IN OLDER ADULTS WITH DIABETES: LEVERAGING BEHAVIORAL ECONOMICS AND USER-CENTERED DESIGN TO DEVELOP CLINICAL DECISION SUPPORT.

Devin M. Mann; Sara K. Chokshi; Hayley Belli; Saul Blecker; Caroline Blaum; Roshini Hegde; Andrea B. Troxel. NYU School of Medicine, New York, NY. (Control ID #3184949)

BACKGROUND: Older adults with diabetes continue to be overtreated despite current guidelines recommending less aggressive target A1c levels based on life expectancy. The suboptimal management of this vulnerable population could be due to physicians having conflicting beliefs regarding this guideline or simply lacking awareness, and changing these behaviors is challenging. Clinical decision support (CDS) within the electronic health record (EHR) has the potential to address this issue, but effectiveness is undermined by alert fatigue and poor workflow integration. Incorporating behavioral economics into CDS tools is an innovative approach to improve adherence to these guidelines while reducing physician burden, and offers the promise of improving care in this population.

METHODS: We applied a systematic, user-centered approach to incorporate behavioral economic "nudges" into a CDS module and performed user testing in six pilot primary care practices in a large academic medical center. To build the nudges, we conducted: (1) semi-structured interviews with key informants ($n=8$); (2) a two-hour design thinking workshop to derive and refine initial module ideas; and (3) semi-structured group interviews at each site with clinic leaders and clinicians to elicit feedback on the module components. Clinicians were observed using the module in practice; detailed field notes were collected and summarized by module idea and usability theme for rapid iteration and refinement. Frequency of firing and user action taken were assessed in the first month of implementation via EHR reporting to confirm that module components and reporting were working as expected, and to assess utilization.

RESULTS: Insights from key stakeholder and clinician group interviews identified the refill protocol, inbasket lab result, and medication preference list as candidate EHR CDS targets for the module. A new EHR navigator section notification and peer comparison message, derived from the design workshop, were also prototyped and produced. User feedback from site visits confirmed compatibility with clinical workflows, and contributed to refinement of design and content. The initial prototypes were first piloted at two sites, refined, and then activated at an additional four additional sites. Preliminary results for the six clinics indicate that

over approximately 31 weeks: 1) the navigator alert fired 1047 times for 53 unique clinicians, and 2) the refill protocol alert fired 421 times for 53 unique clinicians. Reports for the other "nudges" are in development.

CONCLUSIONS: Integrating behavioral economic nudges into the EHR is a promising approach to enhancing guideline awareness and adherence for older adults with diabetes. This novel pilot will demonstrate the initial feasibility and preliminary efficacy of this strategy and determine if a full-scale effectiveness trial is warranted.

ADDRESSING SOCIAL ISOLATION TO IMPROVE THE HEALTH OF OLDER ADULTS: A RAPID EVIDENCE REVIEW CONDUCTED FOR THE AHRQ EPC PROGRAM

Martha Gerrity; Stephanie Veazie; Jennifer Gilbert; Kara Winchell; Allison Schmidt; Robin Paynter; Jeanne-Marie Guise. Portland VA Research Foundation, Portland, OR. (Control ID #3185567)

BACKGROUND: Addressing social determinants that lead to poor health outcomes in the aging U.S. population is a growing public health concern. Social isolation and loneliness in older adults is associated with worsening physical and mental health. Consequences of aging such as health deterioration, loss of family and friends, and reduced mobility can lead to social isolation and loneliness. We conducted a rapid evidence review evaluating the effects of interventions targeting social isolation/loneliness in older adults.

METHODS: This topic was nominated to the AHRQ EPC Program for a rapid review by a healthcare system and was felt to be an important issue facing health systems, providers, community organizations, and the public. Streamlined systematic review methods were used, including conducting targeted searches in Ovid/Medline®, PsycInfo®, and CINAHL® from 2013 to 2018 for systematic reviews and from 2016 to 2018 for primary studies. Studies were evaluated using pre-specified inclusion criteria and assessed for risk of bias. Study characteristics were extracted, including measurements of social isolation/loneliness, health, health care utilization, and harms, and data were synthesized into evidence tables.

RESULTS: Sixteen studies (seven randomized controlled trials, eight pre-post, and one cross-sectional with post-test survey) totaling 17,656 participants age 60 or older were included. Eight were good- or fair-quality studies. Four interventions reported a positive effect on social isolation/loneliness or health outcomes. A resistance training program that included nutrition, and psychosocial support reported improved functionality, depression, diet, and social capital, a physical/leisure activity intervention reported improved quality of life but not social support, and a group tai chi intervention and a facilitated group discussion intervention both improved loneliness but not health outcomes. Three of these four interventions reporting positive outcomes involved a health care professional and met more than once per week. Five of the sixteen studies reported on harms; none were clinically significant, and three reported on health care utilization.

CONCLUSIONS: Physical activity interventions to reduce social isolation show the most promise to improve the health of older adults, but the effects were inconsistent and the studies measured short-term outcomes. Overall we found striking variation in outcomes measured across studies and inconsistency in definitions for social isolation and loneliness. Just over a quarter of studies reported on harms and our search revealed very little information on healthcare utilization, a pressing issue for healthcare delivery systems. These findings suggest that health systems should rigorously evaluate their own programs and make their findings available in order to increase the evidence base on this pressing national issue.

ADHERENCE TO WEIGHT TELEMONITORING PREDICTS REDUCED EMERGENCY DEPARTMENT AND HOSPITAL UTILIZATION AMONG PATIENTS WITH HEART FAILURE

Sarah C. Haynes¹; Daniel Tancredi¹; Patrick S. Romano². ¹University of California, Davis, Sacramento, CA; ²UC Davis, Sacramento, CA. (Control ID #3185710)

BACKGROUND: Weight telemonitoring may be an effective way to improve patients' ability to manage heart failure and prevent unnecessary utilization of health services. However, effectiveness of such interventions is dependent upon patient adherence to daily weighing. Adherence is complex and may change in response to triggering events, such as a hospital readmission or emergency department (ED) visit. Conversely, lower or higher adherence in a given week may help to predict events (rehospitalization, ED visits, or death) in the following week. The objectives of this study were 1) to compare adherence in the two weeks preceding an event to adherence in the two weeks following the same event and 2) to examine the relationship between adherence to daily weighing and the occurrence of events in the following week.

METHODS: The Better Effectiveness After Transition- Heart Failure (BEAT-HF) trial examined the effectiveness of an intervention involving wireless remote telemonitoring and health coaching, compared to usual care, for patients discharged to home after hospitalization for decompensated heart failure. Participants were patients aged 50 and older who were actively treated for decompensated heart failure and discharged to their home after the enrollment hospitalization at one of six academic medical centers in California. Participants were followed for 180 days and were instructed to transmit weight readings daily. For this secondary analysis we used Poisson regression to determine the within-person effects of adherence on the rate of events as well as the effect of events on subsequent adherence.

RESULTS: On average, participants adhered to daily weighing on 52.3% of possible days. 292 participants experienced at least one hospitalization or ED visit during the study period. After controlling for the number of previous events, the rate ratio for adherence decreased by a factor of 0.87 in the two weeks after an event compared with the two weeks prior to the event (95% CI: 0.83-0.92, p=0.000). Adherence also predicted events in the following week; an increase in adherence by one day decreased the rate ratio for experiencing an event by a factor of 0.88 (95% CI: 0.86-0.91, p=0.000).

CONCLUSIONS: Lower adherence in a given week is associated with increased risk of experiencing a rehospitalization, ED visit, or death in the subsequent week. Experiencing a rehospitalization or ED visit did not have the expected effect of triggering an increase in adherence; rather, events had the effect of diminishing adherence to daily weighing. Because lower adherence may in itself be a marker of heart failure exacerbation, telemonitoring programs should consider incorporating changes in adherence into the system's feedback structure in addition to changes in weight values. Furthermore, rehospitalizations and ED visits could be more effectively used as teaching moments to improve subsequent adherence to telemonitoring.

ADOPTION OF AN EVIDENCE-BASED FALL PREVENTION PROGRAM IN LARGE ACADEMIC HOSPITALS: A MULTI-SITE QUALITATIVE STUDY OF FACILITATORS AND BARRIERS

Srijesa Khasnabish¹; Eileen Carter^{2, 3}; Jason Adelman²; Lois Alfieri⁴; Mike Bogaisky^{5, 6}; Ann C. Hurley¹; Mary Ellen Lindros⁴; Virginia Ryan⁷; Maureen Scanlan⁴; Alexa Shelley²; Shao Ping Yu²; Patricia Dykes^{1, 8}. ¹Brigham and Women's Hospital, Brighton, MA; ²New York-Presbyterian Hospital, New York, NY; ³Columbia University School of Nursing, New York, NY; ⁴Montefiore, Bronx, NY; ⁵Albert Einstein College of Medicine, Bronx, NY; ⁶Einstein Hospital (Montefiore Medical Center), Bronx, NY; ⁷Brigham and Women's Faulkner Hospital, Jamaica Plain, MA; ⁸Harvard Medical School, Boston, MA. (Control ID #3162189)

BACKGROUND: Inpatient falls lead to adverse outcomes and prolonged hospital stays. Fall TIPS (Tailoring Interventions for Patient Safety) is a patient-centered fall prevention program that provides clinical decision support. We previously tested this tool in a randomized control trial and demonstrated a 25% reduction in falls. We used qualitative methods to explore the facilitators and barriers to the adoption of Fall TIPS across three large academic health systems (Partners HealthCare, Montefiore Medical Center, and New York-Presbyterian).

METHODS: A semi-structured interview guide based on the RE-AIM framework (reach, effectiveness, adoption, implementation, and maintenance) was used. We interviewed 50 patients and families and 71 staff members in focus groups in 2 phases (Phase 1: July-Sept 2017 and Phase 2: May-June 2018 to validate Phase 1 themes). Upon verbal consent from participants, interviews were recorded, transcribed, and reviewed for accuracy. Transcripts were analyzed in NVivo (QSR International, London) using basic content analysis.

RESULTS: Of the 50 patients and families interviewed, 30 (60.0%) were 65 years, 30 (60.0%) were female, and 22 (40.0%) were white. Of the 71 staff members interviewed, 66 (93.0%) were nurses; the mean (SD) age was 38.62 (1.57), 64 (90.1%) were female, and 25 (35.2%) were white. Fall TIPS changed the paradigm of fall prevention. Pre-implementation, fall prevention consisted of one-size fits all approaches that were staff-driven and lacked actionability (e.g., falls bracelets for "high" risk fall patients). Post-implementation, patients were engaged in the identification and implementation of interventions to address individualized fall risk factors (e.g., walking assistance for patients with medical equipment). Dominant facilitators to the adoption of Fall TIPS included 1) staff motivation and engagement, driven by leadership's prioritization of fall prevention and recognition that prior fall prevention programs were ineffective; 2) patients welcoming their role in fall prevention and Fall TIPS bedside posters that facilitated patient engagement; and 3) information technology (IT) that supported the integration of Fall TIPS into staff workflows (e.g., clinical decision support tools that linked evidence-based interventions to fall risk factors). Dominant barriers included: 1) workarounds that threatened program sustainability (e.g. educating not engaging patients in fall prevention); and 2) difficultly engaging willful patients or those with cognitive impairments in fall prevention.

CONCLUSIONS: Barriers and facilitators to Fall TIPS included staff-level, patient-level and system-level (IT) considerations. Hospitals interested in adopting Fall TIPS should use hospital leadership to motivate staff in fall prevention, harness patients intrinsic desire to be engaged in their care, and use IT to support the integration of Fall TIPS into staff workflows.

ADVANCE CARE PLANNING IN ADULTS AGED 85 AND OLDER IN A CONTINUING CARE RETIREMENT COMMUNITY.

Rebecca Mullan; Christina Tieu. University of Virginia, Charlottesville, VA. (Control ID #3186018)

BACKGROUND: Advance care planning (ACP) is a process in which patients, in partnership with family and their healthcare team, discuss end of life care and make decisions regarding treatment preferences. These preferences are often documented in an advance directive (AD), with the goal being that patients receive care consistent with their values if they are unable to make decisions for themselves. This is particularly important in an older geriatric patient population (age 85 and older), who are at high risk of hospitalization. However, there is little information in the current literature regarding ACP and patient values in this population. We investigated the completion rates and qualitative components of advanced directives in a geriatric patient population aged 85 and older.

METHODS: We performed a cross-sectional chart review of a geriatric primary care practice based in a continuing care retirement community. Eligible patients were 85 years and older, living within the ambulatory and assisted living community, and receiving care at the clinic. Data abstracted included age, gender, comorbidities, hospitalization or emergency department visit within 90 days, and AD completed. Patients were considered to have an AD if there was a document uploaded and indexed in the Electronic Medical Record (EMR).

RESULTS: There were 192 patients who met the inclusion criteria. The mean age was 91.1 (SD 4.2), and 132 (69%) were female. In terms of comorbidities, 51 (26%) had coronary artery disease, 36 (19%) had congestive heart failure, and 22 (11%) had diabetes. There were 24 (12%) patients who had been hospitalized or presented to the emergency department within 90 days. Of the 192 patients, 24 (12%) had an AD uploaded in their EMR. In 4 of 24 patients, the AD included only a designated power of attorney (POA). In 18 of 24 patients (75%), the AD included language directing a focus on comfort-based treatment in the event of imminent death. Two patients (8%) included information about values to guide treatment decisions.

CONCLUSIONS: Advance directives were documented in the EMR in only a small percentage of patients age 85 and older. The majority of these directives included instructions for comfort-based care in the event of imminent death / medical futility, but only two included information regarding the patient's values to help direct medical care.

ADVANCING EVIDENCE SYNTHESIS FROM EFFECTIVENESS TO IMPLEMENTATION: RECOMMENDATIONS FOR THE INTEGRATION OF IMPLEMENTATION MEASURES INTO EVIDENCE SYNTHESIS APPROACHES

Aaron A. Tierney^{1, 2}; Marie Haverfield³; Mark McGovern⁴; Donna M. Zulman⁵. ¹Stanford University School of Medicine, Mountain View, CA; ²Palo Alto VA Health Care System, Menlo Park, CA; ³Stanford University, Menlo Park, CA; ⁴Stanford School of Medicine, Palo Alto, CA; ⁵Stanford University and VA Palo Alto, Stanford, CA. (Control ID #3168121)

BACKGROUND: The field of implementation science aims to address the time lag and quality chasm between discoveries that could improve health, and the widespread dissemination and adoption of those findings. To close this gap, there is a need for greater attention to the factors that influence dissemination and implementation of evidence-based practices. Evidence synthesis projects (e.g., systematic reviews) could contribute to this effort by collecting and synthesizing data relevant to dissemination and implementation. The objective of this paper is to recommend implementation measures and outcomes that should be considered in evidence syntheses of intervention studies and illustrate the application of these recommendations through a systematic review of doctor-patient communication interventions.

METHODS: Drawing on the implementation science literature, we describe ten implementation measures that should be considered when conducting evidence synthesis: acceptability, adoption, appropriateness, feasibility, fidelity, implementation cost, intervention complexity, penetration, reach, and sustainability. We describe opportunities to assess these constructs, for example by examining clinician satisfaction with an intervention (acceptability), participation/attrition rates (adoption), intervention complexity and time/resource demands (feasibility), the degree to which an intervention is implemented as planned (fidelity), and resources and time required to implement an intervention (implementation cost). As a case example, we describe a systematic review of 29 studies of interventions aimed at improving clinician-patient communication in clinical settings. Using the 29 studies, we illustrate opportunities to abstract the implementation measures using data that are frequently reported.

RESULTS: Among the 29 studies, there was variation in the proportion that reported information relevant to acceptability (48%), adoption (86%), appropriateness (66%), feasibility (62%), implementation cost (79%), intervention complexity (100%), penetration (76%), reach (86%), and

sustainability (24%). Approximately two-thirds (19/28) of studies included a measure of fidelity. While three studies reported a direct measure of cost, in all cases the measure reflected the impact of the intervention on cost, rather than implementation costs. Only 2 (7%) studies contained information related to all 10 implementation measures.

CONCLUSIONS: To fully understand the potential value of an intervention, it is important to consider both its effectiveness and the process, demands, and resource requirements involved in implementation. While there is variation in the degree to which intervention studies currently report implementation factors, there is growing demand for this information. By incorporating implementation considerations, evidence synthesis projects can provide valuable contributions to the dissemination of effective interventions.

ADVANCING REAL-WORLD GAINS IN EFFICACY THROUGH TECHNOLOGY AND SKILL BUILDING (TARGETS). A PILOT EVALUATION OF THE TIME2FOCUS MOBILE APPLICATION FOR DIABETES EDUCATION

Alex H. Cho^{1, 2}; Bryan Batch¹; Dan V. Blalock¹; Susan Spratt¹; Rowena Dolor^{1, 2}. ¹Duke University School of Medicine, Durham, NC; ²Duke Primary Care Research Consortium, Durham, NC. (Control ID #3185784)

BACKGROUND: Type 2 diabetes affects 30 million Americans, and is a significant cause of morbidity and mortality. Self-management support (SMS) is an important component of chronic illness care, and a key pillar of the Chronic Care Model. Face-to-face teaching and static patient education materials can suffer from not being interactive or compatible with mobile lifestyles. Digital applications ('apps') offer an alternative for providing SMS that is convenient, scalable and can incorporate principles of health behavior change. This pilot study tested the real-world deployment of a self-guided mobile app for diabetes education (Time2Focus), which utilizes evidence-based content and gamification to deliver an interactive learning experience across 12 levels, covering healthy eating, physical activity, and diabetes monitoring.

METHODS: Primary care providers in the southeastern US were approached for permission to invite their patients to participate. Eligible patients were 18-89 years old; had a diagnosis of Type 2 diabetes; hemoglobin A1c 8% and <12% in the past 3 months; an active online patient portal account tied to the electronic health record (EHR); and access to an iOS or Android smartphone. Interested patients were emailed a baseline survey, and once this was completed, sent instructions for downloading the Time2Focus app (MicroMass; Cary, NC). They were then invited to begin using the app, taking a week to complete each of 12 levels, but could take longer. After completing all 12 levels, participants were sent a follow-up survey. Our primary outcome was pre-/post-change in hemoglobin A1c (A1c), using values from the EHR. Secondary outcomes included users' engagement with and rating of the app. This study was approved by the Duke University Health System IRB.

RESULTS: Of 1355 potentially eligible patients screened, 780 were ineligible, 169 declined, 205 were unreachable, and 201 were consented. 117 (58.2%) participants completed <1 level, 84 (41.8%) 1 level, 26 (12.9%) completed 1-4 levels, 10 (5.0%) completed 5-11 levels, and 48 (23.9%) completed 12 levels. Those completing one or more levels had a mean pre-/post- A1c change of -0.41%, compared to -0.32% among those who did not. Unadjusted two-tailed t-test was not statistically significant ($p = 0.73$). Net Promoter Score (NPS) was 62.5, indicating those who completed all levels of the app rated it highly and would recommend it to others.

CONCLUSIONS: Interest in using a diabetes education app may signal readiness for improved diabetes self-management, but did not always translate into initial use. The decrease in A1c observed in app users relative to non-users during this limited pilot study was not statistically significant. However, uptake and application of lessons learned from SMS may be delayed; in addition, sample size may have been an issue. Future research is needed to address how to increase engagement in SMS and investigate if

follow-up over a longer period of time demonstrates significant change in outcomes like hemoglobin A1c.

ADVERSE EVENTS EXPERIENCED BY PATIENTS HOSPITALIZED WITHOUT DEFINITE MEDICAL ACUITY: A RETROSPECTIVE COHORT STUDY

Amanda Sekijima¹; Cassandra Sunga¹; Maralyssa Bann². ¹University of Washington School of Medicine, Woodinville, WA; ²University of Washington-Harborview Medical Center, Seattle, WA. (Control ID #3162868)

BACKGROUND: There is evidence that physicians consider a variety of "non-medical" factors (e.g. lack of social support, barriers to access) in hospital admission decision-making out of concern for patient safety, and that patients are hospitalized even in the absence of a level of medical acuity warranting admission. The rationale underlying this decision may overvalue the safety of hospitalization based on an assumption that patients admitted without significant medical acuity are not subjected to the same risks as acutely medically ill patients. To our knowledge, this question has not been directly investigated. Our study sought to quantify adverse events (AEs) experienced by patients hospitalized without definite medical acuity in comparison to those who had a definitely medically appropriate indication for admission.

METHODS: This was a retrospective cohort study of 300 admissions from 2/1/2018 to 6/1/2018 in an urban academic medical center. We defined the exposure as hospitalization without definite medical acuity, as assessed by an attending physician faculty member upon admission. Chart review using the IHI Global Trigger tool method was used to measure AEs. UW IRB approval was granted for this study.

RESULTS: 748 admissions from the Emergency Department to a general medical floor were included, of which 513 (68.8%) were considered definitely appropriate and 169 (22.6%) were without definite medical acuity. A sample of 150 admissions from each was used to generate cohort groups. No statistically significant differences were observed between groups in terms of age, gender, race/ethnicity, or primary language. There was no difference in the percentage of admissions with AEs between the two groups (27.3% vs. 29.3%; RR 1.05, 95% CI 0.82-1.34 $p=0.70$) nor in AEs per 1000-patient days (76.8 vs. 70.4; IRR = 0.92, 95%CI 0.65-1.30, $p=0.61$). Distribution of severity of AEs was also similar (see Table 1).

CONCLUSIONS: Our findings demonstrate that patients who are admitted without definite medical acuity are exposed to the same risk of experiencing an AE as those who have a definitely appropriate indication for admission. Further study into the underlying reasons for these admissions and refinement of the risk/benefits surrounding the decision to admit is warranted.

AIM TO IMPROVE FOLATE ORDERING IN NORMOCYTIC AND MACROCYTIC ANEMIA AT LENOX HILL HOSPITAL

Marcus Calderon^{1, 2}; Andrew A. Moses²; Rebecca Mazurkiewicz³; Maria DeVita³. ¹Providence Hospital, Canton, MI; ²Lenox Hill Hospital, New York, NY; ³Lenox Hill Hospital, New York, NY. (Control ID #3185189)

BACKGROUND: Anemia is one of the most commonly diagnosed issues in the hospital setting, and the workup often is costlier than the treatment. Per the Choosing Wisely initiative in 2017, folate testing should not be ordered as it is cheaper to simply supplement it in macrocytic anemia and testing is not indicated in normocytic or microcytic anemia. Despite this, previous studies have shown that folate testing continues unabated in hospital settings. We hypothesized that folate testing was not ordered appropriately by the internal medicine service at Lenox Hill Hospital, a community hospital in New York City.

METHODS: We conducted a retrospective chart review including all adult patients admitted to the medicine service at Lenox Hill Hospital from July 2017 to January 2018 with Folate, Serum. Iron studies ordered at the

same time in order to better select for patients who had folate ordered as part of an anemia work up as opposed to other indications. In this way iron testing was used as a surrogate for anemia analysis. Patients whose test was cancelled before resulting or with duplicate orders were excluded. Additionally, we administered an anonymous 3-question survey to housestaff for self-assessment and to determine the obstacles for ordering serum folate levels properly. An educational email and brief reminders in group settings were used to instruct regarding folate testing. The incentive was a free group meal if folate testing was lowered by 50% in a one-month test period in May 2018. These emails included the current literature about folate testing, the rationale behind our study and intervention, and a reminder about the incentive. The post-intervention chart review was conducted in a similar fashion to the first. Data was acquired from Sunrise, the hospital's electronic medical record and analyzed using MS Excel.

RESULTS: We identified 833 patients with an order for folate in the initial chart review, all with Mean Cell Volumes (MCV) less than 100 (normocytic to microcytic range). None of these had a folate level consistent with diagnosis of folate deficiency. Concurrent iron testing was performed in 472 (57%). Thirty-five out of 60 residents (58%) responded to the survey. Of those, only 8 (23%) answered that they would order folate in a normocytic or microcytic patient, and 9 (25%) answered that they would order folate no matter the MCV. In the post-intervention period of May 2018, 90 orders of serum folate in MCVs <100 were ordered, which was about a ten percent decrease from the average of the initial review period.

CONCLUSIONS: Our study was one of the first to look at proper anemia testing to exclude a test, namely folate, as a cost and blood saving measure for hospitals and patients. The initial review period showed that folate testing was an unnecessary expenditure and should not be taken as part of the routine workup for anemia. The cost of folate testing to the system and to the patient may seem negligible, but the follow up testing and blood draws can cause undue harm.

AIMING FOR EQUITY: EXPLORING PATIENT PREFERENCES FOR ASSISTANCE WITH SOCIAL DETERMINANT OF HEALTH (SDOH) BARRIERS IN PATIENTS WITH UNCONTROLLED TYPE 2 INSULIN-DEPENDENT DIABETES (IDDM) SEEKING CARE AT A SAFETY-NET HOSPITAL

Natalie K. Levy¹; Agnes Park¹; Daniela Solis¹; Binhuan Wang³; Aisha Langford³; Lu Hu²; Erin Rogers⁴. ¹NYU School of Medicine, Bellevue Hospital, New York, NY; ²New York University Langone Medical Center, New York, NY; ³New York University, New York, NY; ⁴NYU School of Medicine, New York, NY. (Control ID #3180675)

BACKGROUND: Health equity can broadly be defined as giving people the opportunities and resources needed to maximize health regardless of socially determined circumstances. SDoH are economic and social conditions that lead to differences in health status. We practice medicine at a mission driven safety-net hospital and provide care to patients with uncontrolled type 2 IDDM. Understanding not only these patients' SDoH barriers, but also their preferences for assistance, is the first step in providing equitable help.

METHODS: We used surveys and interviews to learn about 3 themes: SDoH barriers that impacted the ability to care for one's diabetes, desirable service features of any assistance program, and the types of services patients feel are needed.

RESULTS: We learned that 84% of patients had >1 barrier to health care access, 54% were *unable* to pay for >1 essential item when it was needed, 53% reported >1 barrier in their built environment, 47% reported >1 issue with health literacy, and 37% shared that they only saw or talked to someone that they cared about or felt close to <2 times per week. In the process of defining SDoH barriers, we also learned about unhealthy behavior patterns: 69% of patients have inadequate fruit and vegetable consumption, 57% get no leisure-time physical activity, 48% sometimes or often miss a day of checking their blood sugar, 35% sometimes or often miss doses of their medications and 30% are unable to follow up with their doctor in the time frame they are given.

Despite their obstacles, patients felt that they didn't need "help". While they did share preferences on desirable service features, they volunteered very little regarding desirable types of services. Their lack of suggestions on service features was a finding in and of itself, warranting further exploration. In the end, we gauged interest in currently available resources at our hospital and in NYC, as well as our team's ideas for potential new programs to tackle some of the unhealthy behavior patterns we learned about (see types of services below). The service features that were a priority for any assistance program were: doctor knows about the program (86%), cost (87%), program is in-person (83%), program sends reminders (74%), program is a group class (74%), program is close to home (70%). In terms of types of services, 70% of patients want to learn about Farmer's markets as a source to eat more produce, 65% want to use the pedometer program we are developing and up to 45% want to use Bellevue's new Diabetes Patient Navigator program for assistance with barriers to health care access, taking diabetes medications, and checking blood sugar.

CONCLUSIONS: Patients with uncontrolled type 2 IDDM at our safety-net hospital have significant SDoH barriers, multiple service feature preferences, and are interested in programs currently available and under development. Understanding patient preferences for assistance is a key step in creating solutions that provide equity for underserved patients in need.

ALL-CAUSE MORTALITY AND NEUROLOGICAL OUTCOMES OF TARGETED TEMPERATURE MANAGEMENT AFTER CARDIAC ARREST: META-ANALYSIS

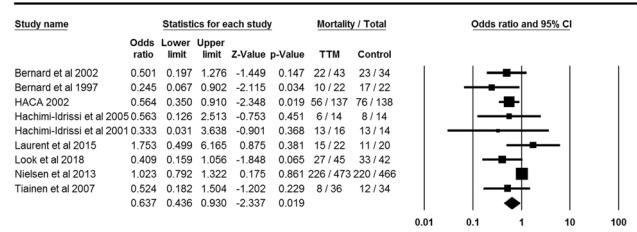

Mohammed Abdalla¹; Abdelnasir Mohamed¹; Wiam Mohamed²; Khlwad Khtab². ¹Saint Francis Hospital, Evanston, IL; ²University of Khartoum, Khartoum, Sudan. (Control ID #3185541)

BACKGROUND: Cardiac arrest carries a high mortality and morbidity. Different studies showed conflicting data regarding outcomes of targeted temperature management (TTM) for cardiac arrest. The purpose of this meta-analysis is to systematically determine the effect of TTM on all-cause mortality and neurological outcomes post cardiac arrest.

METHODS: We conducted a systematic search for randomized controlled trials in Pubmed, Cochrane & ScienceDirect. Primary outcomes were neurological outcome and all-cause mortality.

RESULTS: Nine randomized controlled trials utilizing data for in-hospital and out-of-hospital cardiac arrest were selected for the meta-analysis. Number of patients included was 1,592. Mortality was lower in targeted temperature management group (OR 0.637, 95% CI 0.436-0.93, p-value 0.019, $I^2=44.78\%$, n=1,592). These results were statistically significant. Therapeutic hypothermia group also demonstrated reduction with regard to poor neurological outcomes (OR 0.582, 95% CI 0.363-0.931, p-value 0.024, $I^2=56.79\%$, n=1567). We conducted subgroup analysis after we excluded in-hospital cardiac arrest patients and results showed statistically significant reduction in poor neurological outcomes (OR 0.562, 95% CI 0.331-0.955, p-value 0.033, $I^2=61.78\%$, n=1480) and also showed mortality reduction in out-of-hospital cardiac arrest (OR 0.674, 95% CI 0.454-0.999, p-value 0.049, $I^2=43.8\%$, n=1,505).

CONCLUSIONS: Targeted temperature management after cardiac arrest may be associated with improvement in all-cause mortality and reduction in poor neurological outcome.

Forest plot for all-cause mortality of targeted temperature management after cardiac arrest

AMBIVALENCE TOWARD OPIOID TAPERING AMONG VETERANS ON LONG-TERM OPIOID THERAPY

Anne Hale²; Evan Carey²; Lindsay B. Miller³; Charlotte Nolan⁴; Erin E. Krebs⁵; Joseph W. Frank¹. ¹University of Colorado School of Medicine, Aurora, CO; ²Veterans Affairs, Denver, CO; ³VA Eastern Colorado Healthcare System, Aurora, CO; ⁴Veterans Health Administration, Denver, CO; ⁵Minneapolis VA Health Care System, Minneapolis, MN. (Control ID #3185906)

BACKGROUND: There is inadequate evidence of benefit from long-term opioid therapy (LTOT) and growing evidence of harms. Expert guidelines recommend weighing the risks and benefits of LTOT, and if risks outweigh benefits, recommend reducing or discontinuing LTOT. Many patients on LTOT report ambivalence about opioid medications but patient perspectives on opioid tapering are not well understood. To better understand patient perspectives on opioid tapering, we examined patient-reported importance, readiness, and confidence in their ability to taper opioid medications.

METHODS: We conducted a cross-sectional study within a national prospective cohort study, the Effects of Prescription Opioid Changes for Veterans (EPOCH) Study. The EPOCH Study identified Veterans on LTOT, defined as 150 days' supply in 180 days with no gaps >40 days, and 9,253 Veterans completed a baseline survey in 2015 (92% by mail, 8% by phone). We randomly selected 600 Veterans who met two criteria at EPOCH baseline: 1. completed mail survey; and 2. prescribed 50mg morphine equivalent daily dose (MED). We completed structured phone interviews at the 18-month EPOCH timepoint among 316 Veterans (53% response rate). We assessed self-reported past year opioid tapering or discontinuation and 11-point scales of importance, readiness and confidence related to opioid tapering ("On a scale of 0 to 10, where 0 is 'not at all important' and 10 is 'extremely important', how important do you think it is to cut down or stop using opioid medicines?"). Data on demographics, medications and diagnoses were obtained from the electronic health record. We used t-tests and chi-square tests to examine bivariate associations between past year opioid tapering and these 11-point scales responses.

RESULTS: The study sample was primarily age 60 years or older (73%), male (92%), and White (87%), and the most common pain diagnoses were back pain (76%) and other joint pain (46%). Opioid medication doses at EPOCH baseline were 50-99mg MED (53%), 100-199mg MED (37%) and 200+mg MED (10%). A majority (190/316, 60%) reported tapering in the past year or discontinuing opioid medications. Responses ranged from 1-10 for all three scales. Individuals who reported past year opioid tapering or discontinuation reported significantly higher levels of importance, confidence and readiness related to opioid tapering (Table).

CONCLUSIONS: Veterans on long-term opioid therapy report ambivalence about opioid tapering or discontinuation. Measures of importance, readiness, and confidence are associated with prior opioid tapering experience. Future studies should examine the utility of these scales to support behavior change in the context of opioid tapering as well as the relationship between patient-reported ambivalence and subsequent opioid dose reduction.

AMBULATORY HOLTER MONITORING VERSUS OUTPATIENT 12-LEAD EKG IN PATIENTS WITH CHRONIC ATRIAL FIBRILLATION

Anand Muthu Krishnan¹; Usama Bin Nasir¹; Gaurav Manek¹; Supriya Tigadi²; Heiko Schmitt². ¹University of Connecticut, Farmington, CT; ²UNIVERSITY OF CONNECTICUT, Farmington, CT. (Control ID #3168575)

BACKGROUND: Ambulatory Holter monitors are frequently used for evaluation of rate control in patients with persistent or permanent atrial fibrillation. The use of Holter monitors for this purpose is not mentioned in the current AHA/ACC atrial fibrillation guidelines. We sought to determine the correlation of average heart rate as reported by the 24 hour Holter monitor with that reported on clinic based 12-lead EKG

METHODS: We retrospectively searched the electronic Holter monitor database at the University of Connecticut John Dempsey hospital from the period of 2008 to 2018. The inclusion criteria were the presence of continuous atrial fibrillation throughout the Holter monitor, a resting outpatient 12-lead ECG showing atrial fibrillation that was performed within 30 days of the Holter monitor. Patients with paroxysmal atrial fibrillation, other atrial or ventricular rhythms on the Holter monitor or 12-lead ECG were excluded from the study. Mean heart rate on the Holter monitor was compared to resting ventricular heart rate on 12- lead ECG. Statistical analysis was performed using JMP software.

RESULTS: In total, 227 patients were identified who underwent ambulatory Holter monitoring for the indication of atrial fibrillation. From the 227 Holters reviewed, 89 patients were identified to have persistent or permanent atrial fibrillation and have a 12-lead EKG performed within 30 days of Holter monitor. The Pearson's correlation coefficient for resting heart rate and mean Holter heart rate was 0.78 reaching statistical significance, P<0.0001. (figure 1)

CONCLUSIONS: In patients with permanent atrial fibrillation, mean heart rate from Holter monitors correlates with resting heart rates on 12-lead EKG that was performed within 30 days of Holter monitor. These results indicate that Holter monitoring might not be necessary in evaluating heart rate in patients with persistent or permanent atrial fibrillation.

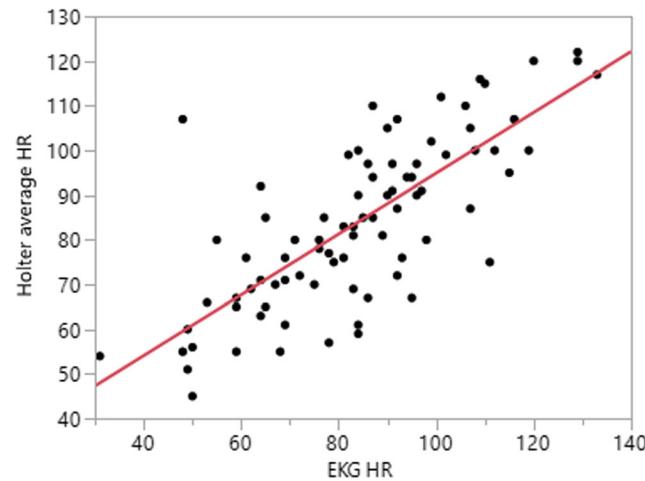

Figure 1

AN ACCEPTABILITY STUDY OF HEALTHCARE NEED AND UTILIZATION IN STREET-BASED PERSONS WHO INJECT DRUGS IN CHICAGO

Anna Solotskaya^{1,2}; Rachel Bernard²; Karim G. Khan²; Shaveta Khosla²; Antonio D. Jimenez²; Stockton Mayer². ¹OHSU, Portland, OR; ²University of Illinois - Chicago, Chicago, IL. (Control ID #3177350)

BACKGROUND: Injection drug use (IDU) is associated with significant morbidity and mortality. Persons who inject drugs (PWID) suffer from a number of psychiatric, chronic and acute illnesses. Despite their healthcare needs, this population has poor integration with primary care and preventative health services. As such, PWID are particularly difficult to study and have high burdens of disease.

METHODS: We confirmed the acceptability of conducting a research study through the use of a mobile outreach van with a population of

PWID. This study assessed the perceived healthcare needs and healthcare utilization of a population of PWID and assessed the acceptability of providing preventative services and care through a mobile outreach van. In 2016 - 2017 we conducted a survey of PWID who utilize a mobile outreach van. We interviewed adult individuals with a history of recent IDU from various parts of the city of Chicago. A brief 5-10 min questionnaire was used to collect data.

RESULTS: 67 persons were enrolled in the study - 59 participants from the west side and 7 from the south side of Chicago. Mean age was 37 and 74.6% were male. 73% of respondents had recent contact with the medical system for conditions such as skin and soft tissue infections (SSTI), mood disorders, and drug and alcohol treatment. SSTIs were a major factor for seeking healthcare with many individuals requiring hospitalization and antibiotics. Mental health disorders were highly prevalent in this population. 91% of participants surveyed were attracted to receiving healthcare services in a mobile outreach setting.

CONCLUSIONS: Healthcare utilization is high in PWID for acute and chronic illness. Services aimed at reducing SSTIs and managing psychiatric illness may be especially effective at reducing healthcare costs and improving quality of life for PWID. This project demonstrates that it is acceptable and desired by a population of PWID to provide quick preventative services and healthcare through a mobile outreach vehicle.

AN ANALYSIS OF HEALTHCARE UTILIZATION AMONGST UNDOCUMENTED PATIENTS 2014-2018

Joseph Nwadiuko¹; Jashalynn German²; Kavita Chapla²; Frances Wang²; Sarah Polk². ¹University of Pennsylvania School of Medicine, Philadelphia, PA; ²Johns Hopkins School of Medicine, Baltimore, MD. (Control ID #3180753)

BACKGROUND: The deportation of undocumented immigrants has increased since the 2016 presidential election. The increased rate of immigration enforcement might discourage undocumented patients from receiving healthcare.

METHODS: The following study analyzes primary care utilization amongst a pool of low-income, Medicaid ineligible patients and Medicaid controls across eight adult and pediatric clinics in a mid-Atlantic health system between 2014-2018. Medicaid ineligible patients were identified by membership in charity and sliding scale programs sponsored by the health system that provide primary care access to a predominantly (92%) undocumented immigrant pool. Using a difference-in-difference approach, our goal was to determine whether there were any changes in the number of scheduled primary care visits between November 9, 2016 (the 2016 general election) and May 31, 2018, with January 1, 2014-November 8, 2016 serving as a reference period. To be included in analysis, patients must have had a single visit between January 1, 2014-October 31, 2015 covered by Medicaid or the charity/sliding program and not have died before the election. Visit records were drawn using the health system's electronic record system. Estimates were calculated using linear and Poisson mixed effect models, controlling for age and gender.

RESULTS: There are 17,504 patients in the sample, 1,429 (8%) in the cohort group and 16,075 (92%) in the control group. The average pre-election number of visits per person per year was 4.54 in the control group and 2.55 in the cohort group. Compared to before the election, there was a decline to an average of 1.28 (-49.6%) visits amongst cohort patients and an average of 3.06 (-32.7%) visits amongst controls, for an adjusted difference-in-difference relative decline of -13.3% (95% CI -21.9%, -3.77%, p=0.007). This effect was exaggerated in adults (difference-in-difference -34%, 95% CI -37.4%, -29.4%) and sliding-scale patients (-20.4%, 95% CI -34.9%, -0.27%). An adjusted time trend analysis showed however that visits in the cohort group fell from an average of 1.82 visits/quarter during the first quarter of 2014 to 0.34 visits per quarter in the final quarter of 2015 with little change between late 2016 and 2018. There was no significant difference-in-difference in no-show rates between groups (+3.38%, 95% CI -0.40%, +7.18%).

CONCLUSIONS: There is a larger decline in the number of visits in undocumented patients than Medicaid patients between 2014 and 2018, but it is not associated with changes around the 2016 election/2017 inauguration period. The true cause for the decline is unclear and needs further investigation. While there is no difference in clinic visits attributed to the election, the results do shed insight into substantial differences in the care trends of Medicaid and undocumented patients.

AN AUDIT SURVEY OF ACCESS TO OFFICE-BASED BUPRENORPHINE TREATMENT IN STATES WITH HIGH RATES OF OPIOID-RELATED MORTALITY

Tamara Beetham¹; Brendan Saloner³; Sarah E. Wakeman²; Marema Gaye¹; Michael L. Barnett¹. ¹Harvard T.H. Chan School of Public Health, Boston, MA; ²Massachusetts General Hospital, Charlestown, MA; ³Johns Hopkins University, Baltimore, MD. (Control ID #3181457)

BACKGROUND: While it is widely acknowledged that access to treatment for opioid use disorder (OUD) is a challenge for patients, little is understood about the diverse barriers that patients encounter in the process of seeking treatment due to appointment availability, wait times, and cost. Understanding the nature of these patient-facing barriers is crucial to design effective policy. To study these barriers, we contacted clinicians as "secret shoppers" requesting buprenorphine, a highly effective medication for OUD treatment.

METHODS: We performed an audit survey from August-October 2018 contacting randomly chosen publicly-listed buprenorphine prescribers twice, posing as uninsured or Medicaid-covered patients with active heroin use seeking buprenorphine treatment at the next available appointment. We used public directories of buprenorphine prescribers located in the six states/jurisdictions (Massachusetts, Maryland, New Hampshire, West Virginia, Ohio, and the District of Columbia) with the highest opioid-related mortality in the United States in 2016 to define our sample. Rates of new appointments offered, whether buprenorphine prescription was possible at the first visit, wait times, and out-of-pocket cost for the first appointment were measured. We used linear regression models with clinician random effects to account for the clustering of outcomes within clinicians contacted twice.

RESULTS: Among 1,092 contacts with 546 clinicians, schedulers were reached for 849 calls (78% response rate), of whom 58% were offered a new appointment with a buprenorphine prescriber and 34% were offered an appointment with the possibility of buprenorphine prescription at the first visit. Callers with Medicaid coverage were less likely than uninsured/self-pay callers to be offered any appointment (54% vs. 62% of contacts, p=0.02) or possible buprenorphine at the first visit (27% vs. 40% of all contacts, p<0.001). The median wait time to first appointment was 5 days (IQR 2-10) while the median additional wait to buprenorphine availability was 6 days (IQR 2-14). The median cost of appointment(s) up to induction for a patient paying cash was \$250 and 52% of contacts reported additional charges necessary for urine or other laboratory tests prior to induction.

CONCLUSIONS: Many buprenorphine prescribers did not offer new appointments or rapid buprenorphine access for callers with active heroin use, particularly those with Medicaid coverage. For self-pay patients, high out-of-pocket costs and recurring charges for laboratory testing were common. Unexpectedly, the primary barrier to buprenorphine access in this survey was not long wait times, but finding a clinician accepting new patients for rapid treatment. The co-existence of poor access with short wait times suggests that improving access to buprenorphine treatment may require efforts beyond increasing the number of waivered providers, such as better connecting patients to the existing supply of prescribers.

AN UNTAPPED POTENTIAL FOR AN INVISIBLE ECONOMY IN PRIMARY CARE? MAKING PATIENT PORTALS WORK FOR CAREGIVERS IN THE SAFETY-NET

Alejandra Casillas¹; Anupama Cemballi²; Anshu Abhat³; Jennifer Portz⁶; Shobha Sadasivaiah⁴; Neda Ratanawongs²; Wagahta Semere⁵; Courtney

R. Lyles⁵; ¹David Geffen School of Medicine @ UCLA, Los Angeles, CA; ²UCSF, San Francisco, CA; ³Harbor-UCLA Medical Center, Pasadena, CA; ⁴University of California San Francisco/Zuckerberg San Francisco General, San Francisco, CA; ⁵University of California San Francisco, San Francisco, CA; ⁶Colorado State University, Denver, CO. (Control ID #3186037)

BACKGROUND: Vulnerable patients within safety-net settings are interested in accessing health information via patient portals, but are less likely to actually use one. Family and friends (in caregiver roles) are important resources to assist these types of patients (i.e. Medicaid recipients, older, and/or Limited English Proficient/LEP) in navigating health systems- and provider support may facilitate caregivers' portal engagement for these patients. We used qualitative methods to explore safety-net providers' perspectives on caregiver/proxy portal use.

METHODS: We conducted 40-60 minute semi-structured interviews with providers from three large California safety-net health systems. The interviews focused on providers' experiences with caregivers, caregiver roles, and how the portal could be leveraged as a tool to support caregivers in their responsibilities. Two coders analyzed the interview transcripts using both deductive and inductive approaches and established consensus regarding major themes.

RESULTS: Of 17 participants interviewed, 4 specialized in geriatrics, and >50% held a leadership/administrative role. The five themes highlight providers' recognition of potential benefits associated with caregiver portal use (Portal positioned to assist caregivers with healthcare tasks; Portal as a tool to directly support caregivers; Expanding portal functionality for caregiver use) and the specific challenges to caregiver portal engagement (Barriers to caregiver enrollment and use; Privacy and security in the caregiver-provider-patient triad). The table shows exemplar quotes.

CONCLUSIONS: Providers recognized the potential for portals to improve information delivery and communication— helping caregivers assist socially and medically complex patients in the safety-net. Further research is needed on assessing and supporting caregivers' interest and ability to access portals across health/digital literacy and English proficiency. Health systems must also address specific strategies to uphold patient preferences while maintaining privacy and security.

ANALYSIS OF VISIT FACTORS ASSOCIATED WITH COLORECTAL CANCER SCREENING IN AN ACADEMIC OUTPATIENT CARE CENTER

Kajali Mishra¹; David E. Willens²; Danielle L. Heidemann². ¹Henry Ford Hospital, Detroit, MI; ²Henry Ford Health System, Detroit, MI. (Control ID #3185949)

BACKGROUND: Colorectal cancer (CRC) is the third most commonly diagnosed malignancy and the second leading cause of cancer related death in the United States. CRC screening recommendations by all major organizations allow for either the use of stool-based tests such as fecal immunochemical test (FIT), fecal occult blood testing (FOBT) and multitargeted stool DNA (such as Cologuard) or visual tests such as Colonoscopy, CT Colonography, and flexible sigmoidoscopy. Prior literature has shown that screening services are inconsistently delivered across practice settings and continue to be underutilized. Most insurance cover preventative visits to accomplish screening goals and offer services in form of outreach, however, data is lacking on effectiveness of these visits. Likewise, interventions to increase CRC screening uptake have focused on modifying provider attitudes, although, studies have not addressed provider level and gender as a potential factor. Our primary objective was to assess the frequency and type of CRC screening offered by primary care doctors. Our secondary objective was to assess how type of visit and provider factors affect if screening was offered and the type of screening offered.

METHODS: A retrospective chart review of 2196 patients who were seen in an outpatient academic tertiary care center was performed. Patients between the ages 50-75 years old who had a primary care doctor and were seen in clinic between July 1, 2017 and July 31, 2018 were assessed. Screening

offered was defined as either stool tests (FIT, FOBT and Cologuard) or visual tests (Colonoscopy and CT colonography).

RESULTS: A total of 2196 patients met our criteria. The mean age was 62.7 years; body mass index (BMI), 31.1kg/m²; females, 54.7%. Cohort was divided into Group A (62%), comprising of people who did not have CRC screening ordered and Group B (38%), who had one or more CRC screening tests ordered. In Group B, some patients had more than one test ordered: 83.1% had Colonoscopy ordered, 10.7% had Cologuard ordered, 13.5% had FIT/FOBT ordered. The rate of colonoscopy completion was 14.7%, and stool testing completion was 34-37.5%. Out of 739 visits during which CRC screening was implemented, 90% were office visits. Surprisingly, having a preventative visit was not associated with an increased likelihood of having CRC screening test ordered ($p=0.91$). Among patients who had either test ordered, 65.6% of Colonoscopies or 48.4% of Stool tests were ordered by residents ($p<0.001$).

CONCLUSIONS: A significant amount of patients (62.3%) that were seen by their primary care doctor had no CRC screening ordered. Having a wellness visit was not associated with having CRC screening tests ordered. Although colonoscopy was the most commonly ordered screening test, compliance to stool testing was twice as that of colonoscopy. Residents as provider were more likely to order colonoscopy compared to senior staff.

ANEMIA PROFILE IN HEART FAILURE: HIGH PREVALENCE OF IRON DEFICIENCY AND SCOPE FOR CORRECTION. A PERFORMANCE IMPROVEMENT PROJECT

Radhika Gali¹; Doris Yang²; Aiman Zafar¹; Beshoy Y. Adly³; Christina Elzahaby³; Fatima Sarwar³; Hamza Ahsan³; Huma Ahmed³; Lakshmi Priyanka Mahali¹; Mohamed Gabr³; Nikita Fernandes¹; Pooja Hebbal⁴; Romaissa Wadood³; Saliha Saleem¹; Saketh Parsi³; Soumya Mamidi²; Sumaira Zareef³; Swathi Pabba¹; Usman Ghani³; Dharmarajan S. Thiruvinvamalar⁵. ¹Montefiore Medical Center, Bronx, NY; ²Montefiore medical center, Bronx, NY; ³Montefiore Medical Center/Albert Einstein College Of Medicine., Bronx, NY; ⁴MONTEFIORE MEDICAL CENTER, BRONX, NY; ⁵Montefiore Medical Center (Wakefield Campus), Bronx, NY. (Control ID #3185676)

BACKGROUND: In the United States, Congestive Heart Failure (HF) is a common reason for hospitalization in those aged over 65 years. Modifiable or addressable risk factors for HF include anemia, chronic kidney disease (CKD), hypertension, obesity, diabetes, arrhythmias, hypothyroidism and others. Anemia is a prognostic indicator, associated with decreased functional capacity, reduced quality of life and worsened outcomes in those with HF.

METHODS: A resident team was trained to provide education to hospitalized HF patients regarding lifestyle, diet, fluids, medication adherence and more. The program participated in the CONNECT-HF multicenter trial, a PI project to track and prevent re-admissions within a month. A tool helped document data on demographics and comorbidity. 139 patients hospitalized with HF (September 2017 - December 2018) were identified; clinical profile and health outcomes were analyzed. Anemia was defined as Hb <12 g/dl in females and <13 g/dl in males (WHO criteria). Our tool identified anemia evaluation (serum iron, ferritin, iron binding capacity, vitamins B12, folate and renal function), to enable appropriate management where possible.

RESULTS: Mean patient age: 70 years. Most hospitalizations occurred for age group 65 years (61%), with 52% males. 99 of 139 patients were anemic, mean Hb 11.4 g/dl. Of the 99 with anemia, 42% had iron deficiency anemia (IDA), 17% had anemia of chronic disease (ACD) and 30% had not undergone evaluation. Of those anemic, 41% had diastolic HF and 59% had systolic HF; 32% had diabetes; 48% had CKD. Among those anemic, 4% had 3 or more co-morbidities (e.g. CKD, diabetes, cognitive impairment, etc). Of those with anemia and HF, 26% were re-hospitalized, whereas the readmission rate in those with HF without anemia was 22%). Among those with iron-deficiency, the readmission rate was 14%. Those with anemia had more unplanned readmissions and longer inpatient stays (avr: 9.8 days, SD: 15), versus HF patients without anemia (avr: 6.4 days (SD: 4.33), (P-value: 0.9).

CONCLUSIONS: Our PI project brought awareness on the high prevalence of anemia (71%) in patients with heart failure. Iron deficiency was present in 42% of HF cases with anemia, but not statistically significant with longer hospital stay and re-admission rates. Anemia of iron deficiency in HF can be easily treated with oral or preferably intravenous iron, resulting in better outcomes (exercise performance, HF symptoms and quality of life). Going forward, our project highlights the importance of routinely evaluating patients with HF and anemia for iron deficiency anemia to consider corrective therapy. Additionally, evaluation for etiology of iron deficiency should be instituted.

ANTIBIOTIC AND ANTIVIRAL PRESCRIBING FOR HOSPITALIZED PATIENTS WITH RESPIRATORY VIRUSES

Abhishek Deshpande; Pei-Chun Yu; Peter B. Imrey; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #3185408)

BACKGROUND: Suspected respiratory infections are the leading cause of antibiotic prescription among hospitalized patients. A significant proportion of pneumonias are caused by viruses, yet it's unclear how often clinicians test for or treat viral pathogens in pneumonia patients. The objective of this study was to quantify the frequency of viral testing in hospitalized patients with pneumonia, measure the proportion with positive respiratory virus tests that are treated with antibiotics and antivirals and compare the outcomes of patients tested for suspected viral infection to those not tested.

METHODS: We included adult patients admitted with pneumonia from 2010 - 2015 to 175 US hospitals participating in the Premier Database and providing administrative and microbiological data. Pneumonia cases were identified via ICD9-CM codes as well as chest radiograph and antimicrobial treatment on the first hospital day. Patients were excluded if they had been transferred from another facility, had cystic fibrosis, or had a hospital length of stay (LOS) of 1 day. We also excluded patients with identical organisms in blood and urine. We compared characteristics, treatment and outcomes of patients who were tested for suspected viral infection to those not tested. Using logistic and linear regression models, as appropriate, we assessed the following outcomes; inpatient mortality, LOS and cost, adjusting for demographics, co-morbidities and treatments.

RESULTS: 178,895 patients met inclusion criteria. The overall viral testing rate increased from 10% in 2010 to 37% in 2015. In 2015, the viral testing rate varied by season from 65% in winter to 17.5% in summer. The rate also varied among hospitals, ranging from 10-72%. Influenza virus was the most frequently tested (22.9%) followed by respiratory syncytial virus (3.9%), with a positivity rate of 10.6% and 2.1%, respectively. Influenza virus accounted for 85% of the 5,318 patients with a positive viral test, followed by rhinovirus (5.7%). Tested patients were younger (67 vs. 71 years), less likely to be admitted from SNF (6% vs. 8%) and had fewer comorbidities (2.9 vs. 3.4) (all comparisons $p < 0.001$). On treatment day 3, among patients with a positive viral test, 23% received antibiotics only, 15% antivirals only, and 56% received both. Compared to patients not tested, those tested were less likely to receive antibiotics (79 % vs. 89%, $p < 0.001$). Viral testing was associated with reduced odds of in-hospital mortality; negative viral test (adjusted odds ratio [aOR] 0.80, 95% CI 0.76-84) and positive viral test (aOR 0.71, 95% CI 0.62-84). Testing was not significantly associated with LOS or cost.

CONCLUSIONS: In a large US inpatient sample hospitalized for pneumonia, only 37% of the patients were tested for viral pathogens in 2015, but testing varied widely by hospital. Influenza testing was most common and most likely to be positive. Although a positive test was associated with antiviral treatment, it had a small impact on antibiotic prescribing.

ANTIHYPERTENSIVE TREATMENT TO LOWER CARDIOVASCULAR RISK AMONG POST-MENOPAUSAL WOMEN ON ESTROGEN REPLACEMENT THERAPY

Tran Nguyen; Talal Alzahrani; Jannet Lewis. George Washington University Hospital, Washington, DC. (Control ID #3139875)

BACKGROUND: Approximately one in every three women between the ages of 40 to 59, and two in every three women aged 60 and above in the United States have hypertension. For older women, estrogen is occasionally used to treat common menopausal symptoms, but increases the risk of cardiovascular events. Although the results of the original Antihypertensive and Lipid-Lowering Treatment to Prevent Heart Attack (ALLHAT) trial showed that hydrochlorothiazide (HCTZ) diuretics are superior to calcium-channel blockers and angiotensin-converting enzyme inhibitors in preventing 1 or more major forms of cardiovascular disease (CVD), there are several reasons why physicians may prefer to avoid

HCTZ in postmenopausal women on estrogen. At least one study has shown that, among postmenopausal women, HCTZ was less well tolerated than moexipril and HCTZ is known to increase blood glucose while postmenopausal status by itself already increases risk of developing diabetes mellitus. The differences in CVD effects of the various first-step drugs specifically among post-menopausal women on estrogen therapy have not been studied and hence, will be investigated in this study.

METHODS: The data of the ALLHAT was utilized to examine the effects of amlodipine versus lisinopril compared to chlorthalidone in a subgroup of women on estrogen. These women were 55 years of age or older with hypertension and at least one other CVD risk factor from 623 North American centers (n=2752). ANOVA test and student t-test were used to compare the baseline characteristics between subjects in each group of therapy. Hazard ratios and 95% confidence intervals (CIs) were obtained from the Cox proportional hazards model to compare the clinical outcomes between the three antihypertensive groups. A composite endpoint of cardiovascular mortality and nonfatal myocardial infarction, stroke, coronary revascularization procedure, angina, heart failure, and peripheral vascular disease was used, as well as each CVD outcome individually and all-cause mortality.

RESULTS: There were no significant differences in the baseline characteristics of the three treatment groups. Compared to chlorthalidone, the hazard ratios for the composite endpoint were 1.03 (95% CI 0.94-1.13, p -value=0.55) for amlodipine and 1.02 (95% CI 0.93-1.12, p -value= 0.64) for lisinopril. Likewise, hazard ratios for all-cause mortality as well as the individual CVD outcomes were not significantly different among either lisinopril or amlodipine compared to chlorthalidone.

CONCLUSIONS: Among women aged 55 years or above on estrogen, calcium channel blockers and angiotensin-converting enzyme inhibitors as initial antihypertensive therapy are associated with similar cardiovascular outcomes compared to thiazide diuretics. Therefore, for post-menopausal women on estrogen replacement therapy, physicians should not feel constrained to use HCTZ, but should instead choose initial anti-hypertensive medication taking into account individual patient's side effect profile and other comorbidities.

APPOINTMENT TIMING AND OPIOID PRESCRIBING

Michael L. Barnett¹; Hannah Neprash². ¹Harvard T.H. Chan School of Public Health, Boston, MA; ²University of Minnesota School of Public Health, Minneapolis, MN. (Control ID #3181483)

BACKGROUND: Rising opioid prescribing has been a major contributor to the national opioid crisis. Many observers have blamed rushed practice environments for high rates of opioid prescribing because opioids can be a "quick fix" for a visit where pain is a symptom. However, there is little evidence examining the magnitude of time pressure on prescribing decisions. We

hypothesized that as the workday progresses and appointments run behind schedule, physicians may be more likely to prescribe opioids to simply "move on," which would be mitigated by scheduled breaks.

METHODS: Using data from athenahealth, a national electronic health record provider, we identified all previously scheduled primary care physician (PCP) appointments from 2013-14 for adult patients with no opioid prescriptions in prior 12 months. Our main outcome was opioid prescribing with secondary outcomes of physical therapy orders and nonsteroidal anti-inflammatory drug (NSAID) prescriptions. We examined average within-physician changes in each outcome by the order of the appointment in the day (groups of 3 appointments from 1st to 21st) and by appointment "lateness" (0-60 minutes late in 10-minute increments). We also examined prescribing rates for visits immediately before and after scheduled breaks of 15 minutes or more. We used multivariable linear probability models adjusting for patient and visit characteristics and included physician fixed effects to control for time-invariant differences across physicians.

RESULTS: Our sample included 408,579 primary care appointments with 2,653 PCPs. Several patient characteristics had statistically significant, but small differences by appointment order (e.g. patients seen in the first 6 appointments vs. the last 6 appointments of the day were less likely to have Medicaid insurance 4.8% vs. 5.3%, P<0.001). The rate of opioid prescribing increased as the workday progressed (1st-3rd appointment: 4.2% [95% CI 4.1-4.3] vs. 19th-21st appointment: 5.1% [95% CI 4.9-5.4], P<0.001), a 22.5% relative increase. Opioid prescribing also increased as appointments ran behind, holding the time of the day constant (4.3% vs. 5.6% for 0-9 vs. 60+ minutes late, P<0.001). Conversely, opioid prescribing fell after a scheduled break of more than 15 minutes, controlling for time of day (5.0% vs. 4.7% before vs. after a break, P=0.006). None of these relationships were present for physical therapy or NSAID prescribing.

CONCLUSIONS: In a large, national sample of primary care appointments, we found that within-provider opioid prescribing increased during the work day and with appointment lateness. Scheduled breaks mitigated this effect to a small degree. These results are consistent with the concept that time pressure, through multiple possible mechanisms, can influence physician decision-making. If similar patterns exist in other clinical scenarios, this phenomenon could have widespread relevance for public health and quality improvement efforts.

APPROPRIATE DIAGNOSIS AND MANAGEMENT OF ACUTE CORONARY SYNDROME BY INTERNAL MEDICINE INTERNS: A NEEDS ASSESSMENT

Akshai Subramanian; Patricia O'Sullivan; Lucas Zier. University of California, San Francisco, San Francisco, CA. (Control ID #3181731)

BACKGROUND: Acute coronary syndrome (ACS) is common and associated with significant morbidity and mortality. We performed a needs assessment to determine the ability of internal medicine interns to accurately diagnose and manage ACS.

METHODS: We conducted a needs assessment using a test with open-ended questions that we administered to internal medicine interns at a large urban medical center four months into their training. We collected demographic data including completion of a cardiology rotation during residency. Using two cases (one demonstrating demand ischemia due to sepsis and one demonstrating ACS) we assessed interns' ability to diagnose ACS, differentiate ACS from other types of myocardial infarction (MI), manage these conditions with guideline-based therapies, and provide a

pathophysiologic basis for each therapy. Ideal responses were determined by a consensus of two cardiologists resulting in a rubric with point values for correct responses. Three individuals scored a sample of responses to determine interrater reliability of the rubric. We descriptively analyzed the number of correct and incorrect responses. We used student's t-test and Fisher's exact test to determine differences between respondents who had completed cardiology rotations and those who had not. Incomplete assessments were excluded.

RESULTS: 81% (52/64) of learners completed the assessment. Interrater reliability for the scoring rubric was excellent (Cohen's for the 17 responses ranged from 0.74 to 1.0). The mean score was 49% ± 19%. In the demand ischemia case, 44% properly managed demand ischemia due to sepsis, 69% of respondents inappropriately treated ACS, and 10% inappropriately managed both sepsis and ACS. In the ACS case, 15% of respondents provided complete guideline-directed medical therapy for ACS and 4% also provided accurate pathophysiologic basis for each therapy. Comparing respondents who had completed a prior cardiology rotation and those who had not, there were no significant differences between mean scores (53% vs. 46%, p>0.20), number of respondents properly managing demand ischemia (p>0.9), and number providing complete guideline-directed medical therapy for ACS (p>0.9).

CONCLUSIONS: In our study, internal medicine interns performed poorly in appropriately diagnosing and managing ACS. Completion of a cardiology rotation was not associated with differences in these abilities. This suggests the need for improved educational methods to promote knowledge acquisition and retention when teaching ACS diagnosis and management.

ARE RESIDENTS' TEST UTILIZATION PATTERNS ASSOCIATED WITH THEIR COMMUNICATION SKILLS AND PATIENT CENTEREDNESS?

Colleen Gillespie¹; Eli Cahan³; Kathleen Hanley³; Andrew B. Wallach²; Barbara Porter³; Sondra Zabar³. ¹NYU School of Medicine, Brooklyn, NY; ²Bellevue Hospital, New York, NY; ³NYU School of Medicine, New York, NY. (Control ID #3185214)

BACKGROUND: It is well documented that few ordered tests are "high value" a significant percentage of those ordered are "low-value." Residency offers an opportunity to teach high-value care and educational interventions to do so have been effective. However, the relationship between high-value care and residents' ability to communicate effectively with patients has not been explored. Ability to establish rapport, gather information effectively, and be patient-centered may impact residents' use of tests. We hypothesize that residents with poor skills in these areas may order tests less efficiently.

METHODS: Unannounced Standardized Patients (USPs) were introduced into residents' primary care clinics in a large urban, safety net hospital to portray 3 clinical scenarios: a well visit, a chief complaint of fatigue, and a diagnosis of asthma. Orders were extracted via chart review. Appropriateness of orders was determined by reference to United States Preventive Services Task Force (USPSTF) and clinical practice guidelines. Excessive tests were defined as not explicitly indicated for the scenario—indicated tests were the converse. Number of excessive and % of indicated tests were calculated across the 3 visits for 48 residents. Communication skills in information gathering (5 items) and developing a relationship (6 items) and a patient-centeredness score (4 items: took a personal interest, answered all my questions) were computed as % of behaviorally anchored items rated as "well done" and included in regression models predicting test utilization.

RESULTS: On average, residents ordered 15% of indicated tests (SD 9%, 0-38%) across the 3 visits and a mean of 1.3 unnecessary tests (SD 1.7, 0-6). In the regression model, the 3 skills explained 16% of variation in unnecessary tests ($p=.047$). Information gathering explained the greatest share (8%, $p=.041$). With all 3 variables in the model, patient-centeredness was positively associated with unnecessary tests (Std Beta=.42, $p=.016$) and information gathering was negatively associated with unnecessary tests (Std Beta=-.34, $p=.041$). Mirroring these results, superutilizers (10 residents ordering ≥ 3 excessive tests) had lower information gathering and relationship development scores than other residents (66% vs 75% and 72% vs 76%) but higher patient centeredness scores (80% vs 74%)-although differences were not significant.

CONCLUSIONS: Our findings suggest that information gathering skills may have a small influence on residents' ordering of excessive tests. Further research with larger samples (adequate power) will help clarify the effect sizes. If our results stand, interventions for high-value care should include information gathering skills and residency programs should continue to reinforce core communication skills training. In addition, our finding that patient centeredness was associated with ordering unnecessary tests suggests that residency programs could caution residents about conflating ordering of tests with patient-centeredness.

ARE SAFETY NET AND SMALLER HOSPITALS BEING LEFT BEHIND UNDER NEW PAYMENT MODELS? IMPACT OF MEDICARE'S MANDATORY BUNDLED PAYMENT PROGRAM ACROSS DIFFERENT HOSPITAL GROUPS

Michael L. Barnett¹; Andrew Wilcock²; J. Michael McWilliams²; Arnold M. Epstein¹; Ateev Mehrotra². ¹Harvard T.H. Chan School of Public Health, Boston, MA; ²Harvard Medical School, Boston, MA. (Control ID #3184192)

BACKGROUND: In 2016, Medicare implemented the Comprehensive Care for Joint Replacement model (CJR), a national mandatory bundled payment model for lower extremity joint replacement (LEJR) in randomly selected metropolitan statistical areas (MSAs). Overall, intervention hospitals reduced spending by 3% vs. control hospitals with no impact on quality. However, there are concerns that hospitals with fewer resources, such as smaller hospitals and safety net hospitals serving a high proportion of vulnerable patients, cannot implement systematic changes needed to respond effectively to this new payment system.

METHODS: We conducted difference-in-differences analyses using Medicare claims from 2013-2017, comparing LEJR episodes in 75 MSAs randomized to mandatory participation in CJR (treatment MSAs) with episodes in 121 control MSAs, before vs. after CJR implementation. Our primary outcomes were institutional spending per LEJR episode (i.e. Medicare Part A), complication rates, the proportion of patients in the highest quartile of predicted spending (a measure of patient selection) and 90-day readmission rates. We categorized hospitals by what fraction of patients were on Medicaid or uninsured patients, as defined through Medicare's disproportionate share hospital (DSH) adjustment, number of beds and for-profit status. Within each subgroup of hospitals, we used linear regression models adjusted for beneficiary and procedure characteristics, and hospital fixed effects.

RESULTS: In 2013-2017 there were 280,161 LEJR procedures in treatment and 377,278 procedures in control MSAs. Hospitals with <100 beds had a smaller decline in institutional spending than those with >250 beds (-\$650 or 2.7% vs. -\$856 or 3.1% relative decrease, $p<0.001$). Hospitals in the highest tertile of DSH percentage had a larger relative decline in institutional spending compared to hospitals in the lowest tertile (-\$1,250 or 4.1% vs. -\$666 or 2.8% relative decrease, $p<0.001$). For-profit hospitals had declines in savings twice as large as savings in non-profit hospitals (-\$1,310 or 5.2% vs. -\$634 or 2.4% relative decrease, $p<0.001$). There was no change or slight decreases in complications or 90-day readmissions across hospital subgroups. In addition, there was no

statistically significant change in the proportion of patients with LEJR procedures in the highest quartile of predicted spending in any subgroup.

CONCLUSIONS: We found little evidence that smaller or safety net hospitals were unable to respond to the bundled payment programs. The difference between the performance of smaller vs. larger hospitals was modest while safety net hospitals had larger spending reductions vs. other hospitals with no apparent negative impact on quality. Despite concerns that Medicare's payment reforms could negatively impact smaller or safety-net hospitals, we found little evidence that this occurred within the CJR program. These results may not generalize beyond LEJR procedures and should be replicated with other payment reforms.

ASSESSING DOCUMENTATION OF CLINICAL REASONING IN ADMISSION NOTES OF PHYSICIANS WORKING IN HOSPITAL MEDICINE

Susrutha Kotwal¹; David Klimpl¹; Sean Tackett²; Regina Landis³; Scott Wright¹. ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Johns Hopkins Bayview Medical Center, Baltimore, MD; ³Johns Hopkins, Baltimore, MD. (Control ID #3140154)

BACKGROUND: High quality clinical documentation is essential for patient safety. Thoughtful clinical documentation transmits one's clinical reasoning and is considered to be a professional responsibility. There are no accepted standards for assessing documentation with respect to clinical reasoning. We therefore undertook this study to establish a metric to evaluate hospitalists' documentation of clinical reasoning in the assessment and plan (A&Ps) section of admission notes.

METHODS: This was a retrospective study reviewing admission notes of hospitalists at 3 hospitals between January 2014 and October 2017. Admission notes were included for patients hospitalized with a diagnosis of either fever, syncope/dizziness, or abdominal pain. A total of 1130 admission notes were identified randomly; notes were excluded if they were not on the hospitalists' service, or if the diagnosis had been confirmed in the emergency department. So as to sample the notes of many providers, no more than 3 notes written by any single provider was analyzed. We developed the 'Clinical Reasoning in Admission Notes Assessment & Plan' (CRANAPL) tool to assess the comprehensiveness of clinical reasoning documented in the A&Ps of admission notes. The tool was iteratively revised during pilot testing; ultimately two authors scored all A&Ps using the finalized version of the CRANAPL tool. These authors also assessed each A&P using single item broad ratings: a 'global clinical reasoning' and a 'global readability/clarity' measure. All data were deidentified prior to scoring. Content, internal structure, and relation to other variables validity evidence were established.

RESULTS: The total number of hospitalists whose admission notes were evaluated was 120. 285 admission notes were reviewed across one community and two academic hospitals. The nine-item CRANAPL rubric includes elements for problem representation, uncertainty, differential diagnosis and plan, as well as items related to length of stay and disposition plans. The mean score for both raters for the total CRANAPL score was 6.4 (SD 2.2), and it varied significantly between hospital sites ($p<0.001$). The ICC measuring inter-rater reliability for both raters for the total CRANAPL score was 0.83 (95% CI 0.76-0.87). Associations between CRANAPL total scores, global clinical reasoning, and global score for note readability/clarity were statistically significant ($p<0.001$). In multivariate regressions after adjusting for covariates, higher scores on the CRANAPL tool were seen among American Medical Graduates as compared to International Medical Graduates ($p<0.05$).

CONCLUSIONS: This study represents a first step to characterize clinical reasoning documentation in Hospital Medicine with real patient notes. With validity evidence established for the CRANAPL rubric, it can be used to assess the documentation of clinical reasoning skills of hospitalists and for providing feedback. This is an essential step to improve the diagnostic process and reduce medical errors.

ASSESSING ENGAGEMENT IN USER-CENTERED DESIGN OF A TEXT MESSAGING APP IN A DIVERSE, SAFETY-NET POPULATION

Sarah Nouri¹; Patricia Avila-Garcia²; Anupama Cemballi¹; Urmimala Sarkar¹; Adrian Aguilera²; Courtney Lyles¹. ¹University of California, San Francisco, San Francisco, CA; ²University of California, Berkeley, Berkeley, CA. (Control ID #3184645)

BACKGROUND: Healthcare systems are rapidly deploying digital tools with the goal of improving chronic disease management, yet few studies evaluate their usability by vulnerable populations. To understand barriers to lower rates of app use among low-income patients, we employed user-centered design (UCD) methods in the development of a new text messaging app. We describe here variations in engagement in design process, with specific attention on patients with limited health literacy (LHL), limited English proficiency (LEP), and limited digital literacy (LDL).

METHODS: We conducted 20 in-person, in-depth, semi-structured interviews in English or Spanish with primary care patients at a safety-net healthcare system. We used open-ended interviews and card sorting tasks to seek input about mobile phones and prioritize text messaging for health behaviors. We used open coding to (1) categorize *mobile phone use* and (2) evaluate engagement in the interview process. Engagement was defined by the frequency and quality of (1) *feedback* on existing text message content and (2) *novel suggestions* for text messages. Based on mobile phone use, we identified participants with LDL; we then quantitatively examined mobile phone use by LHL and LEP. We also evaluated engagement by LHL, LEP, and LDL with Wilcoxon rank sum tests.

RESULTS: Participants were 59 (± 8) years old; 65% women, 90% non-white, 80% with limited LHL, 65% with LEP. All had depression and 70% had diabetes. *Mobile phone use:* Major themes related to texting networks and difficulty with basic (text messaging) and advanced (step tracking, location sharing) features of mobile phones. Nearly all had smartphones and regularly used text messaging, but 16/20 reported difficulty with text messaging due to inability to type, physical disability and low literacy. We identified 8 participants as having LDL; 7/8 also had LEP and/or LHL. *Feedback:* Quality of feedback ranged from yes/no answers to explanations of why a text message was liked or disliked. Frequency of comments was lower in all subgroups, with a significant difference between those with LDL vs adequate digital literacy ($p=0.045$). *Novel suggestions:* Quality of suggestions ranged from text messages that had already been presented to ideas for structural changes to the app. Frequency of suggestions made was lower in those with LEP or LDL ($p=0.02$ and 0.008, respectively); there was no difference by HL.

CONCLUSIONS: Despite widespread mobile phone use, digital literacy barriers are common among vulnerable populations. Engagement was qualitatively and quantitatively lower among those with LHL, LEP, and LDL, suggesting traditional UCD methods (open-ended hypothetical interviews, card sorting tasks) may be less effective for those with literacy or language barriers. Different methods in UCD, such as direct observation, may be more productive in eliciting feedback and matching interventions with end users' needs and preferences.

ASSESSING INTERPROFESSIONAL TEAM FUNCTIONING VIA DIRECT OBSERVATION IN A PRIMARY CARE SETTING

Alana Doonachar²; Lyndonna M. Marrast¹; Aubrey Rogers³; Daniel J. Coletti⁴. ¹Zucker School of Medicine at Hofstra/Northwell, Kew Gardens, NY; ²Hofstra University, Hempstead, NY; ³Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; ⁴Northwell Health, Great Neck, NY. (Control ID #3185574)

BACKGROUND: Improving Patient Access, Care, and Cost through Training (IMPACCT) is an interprofessional (IP) training program developed to enhance primary care training through an interprofessional team approach. Maintaining collaborative and efficient team interactions is

essential to delivering quality care to our underserved patients. We sought to systematically review and evaluate the IP process, describe team dynamics, and assess adherence to clinical workflows including: 1) pre-session huddles; 2) trainee precepting processes, and 3) patient interactions.

METHODS: From March to July of 2018, four raters silently observed IMPACCT clinical sessions and rated behaviors using a tailored version of the Modified McMaster-Ottawa Scale: Team Assessment form. Raters completed quantitative assessments of team-based competency attainment in the following areas: patient communication, team collaboration, role clarification, collaborative patient-family centered approach, conflict management, and (overall) team functioning. Interactions were rated as to "below expected", "at expected" or "above expected" levels of quality. Raters also recorded field notes to add context to the ratings.

RESULTS: A total of 233 team assessment forms were completed. The majority of the observations were made of precepting events (67%), compared to huddle ratings (14%) and observations of patient interactions (19%). The average huddle duration was 23 minutes and included an average of 6 IP team members. Examination of ratings indicated that 70% of the assessments were "at expected" competency level with 27% exceeding expectations. When assessing members' role and responsibilities, the results showed that 52% of the observations were at expected levels and 43% were above expected levels of competency. With regards to conflict management/resolution and team functioning capabilities, both competencies scored over 95% in meeting expectations and going above expected levels. In contrast, teams were less likely to promote a family-patient centered approach: only 43% of the observations demonstrated "at expected" levels and 30% of the assessments were rated as "below expected levels." Overall the global rating score of team assessment was 71% at expected and 28% above expected proficiencies.

CONCLUSIONS: We observed high levels of IP team functioning in a majority of observed domains during team huddles, precepting, and patient interactions. Differences in observations were expected given there is one daily huddle, but multiple precepting events and patient encounters. Results suggest the need to consider ways to incorporate more of a family-systems framework for considering patient strengths and needs. High competency ratings overall, however, are one indicator of success in our faculty development and learner training efforts in team-based care. Future plans include conducting "360 degree" evaluations to permit faculty and trainees to reflect on team processes interactively and engage in self-ratings of team effectiveness.

ASSESSING KNOWLEDGE, PERCEIVED SUSCEPTIBILITY, SEVERITY, BENEFITS, BARRIERS, AND WILLINGNESS OF COLORECTAL CANCER SCREENING IN ARMENIA

Nika M. Harutyunyan¹; Evelyn Abrami²; Taron Torosian³; Shant Shekherdian⁴; Marine Hovhannisyan⁵; Armen Aboulian⁶; Hovhannes Hovhannisyan⁵; Garegin Dallaqyan⁵. ¹UCLA, Sherman Oaks, CA; ²USC, Los Angeles, CA; ³USC, Los Angeles, CA; ⁴UCLA, Los Angeles, CA; ⁵Yerevan State Medical University, Yerevan, Armenia; ⁶Kaiser, Los Angeles, CA. (Control ID #3179997)

BACKGROUND: Colorectal cancer screening (CRCS) has been shown to be cost-effective and life-saving. To date, no organized screening programs for colorectal cancer (CRC) exist in Armenia. Furthermore, little is known about the population's knowledge and attitudes towards CRCS. The purpose of this study is to evaluate knowledge of CRC and CRCS, willingness to participate in various CRCS modalities and barriers to implementation of a successful CRCS program.

METHODS: Following IRB approval, previously validated survey questions using the Health Belief Model were translated and modified for local relevance. Convenience sampling was used at a representative number of outpatient clinics throughout the capital city of Yerevan. Surveys were administered to consenting adults between the ages of 40-65.

RESULTS: Of 368 respondents (54% female), 84% reported having knowledge of CRC, however only 22% percent had heard of tests that can detect CRC. Despite this, 91% of respondents felt that getting checked regularly increases the chances of finding CRC early, and that early detection leads to "excellent" or "good" outcomes. 19% of respondents (n=68) have worried about the possibility of having CRC, and of those, only half (n=35) sought the consultation of a physician regarding this concern. When asked whether they would be afraid of CRCS, 46% answered "yes" (n=87) or "unsure" (n=81). The most common reasons for not undergoing screening were "I don't think it is necessary" (n=221), "I didn't know I should get it" (n=166), "If I don't have symptoms I won't pursue it" (n=156), "I will do it later" (n=156) and "Screening and treatment costs would be too much" (n=153). Only 7% of those surveyed stated that a provider has ever mentioned CRCS screening to them, but 76% were willing to undergo CRCS if their doctor recommended it. There was no strong preference towards any screening modality, however 78% would only undergo screening if free (n=189) or less than 10,000AMD/~\$20USD (n=96).

CONCLUSIONS: Despite the high self-reported familiarity with CRC, knowledge of CRCS in Armenia remains low. While most respondents were willing to undergo CRCS if they were advised to do so, significant barriers to voluntary screening exist. These findings suggest that targeted interventions to directly increase awareness of CRC and CRCS among the population, encouraging healthcare providers to discuss CRCS with patients, and keeping out-of-pocket costs for CRCS and CRC treatment at a minimum should be considered when designing organized CRCS in Armenia.

ASSESSING THE ASSOCIATION OF CRIMINAL JUSTICE CONTACT WITH WELLBEING

Ram Sundaresan¹; Brita Roy¹; Youngmin Yi²; Carley Riley^{3, 4}; Christopher Wildeman²; Emily A. Wang¹. ¹Yale School of Medicine, New Haven, CT; ²Cornell University, Ithaca, NY; ³University of Cincinnati College of Medicine, Cincinnati, OH; ⁴Cincinnati Children's Hospital Medical Center, Cincinnati, OH. (Control ID #3185988)

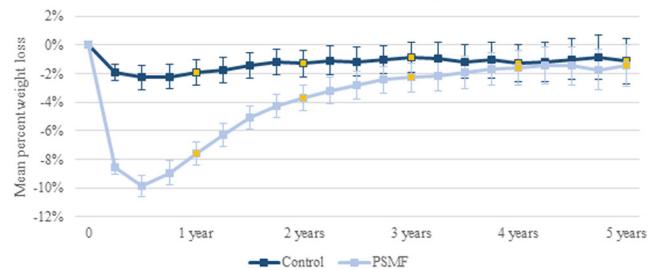

BACKGROUND: Research has shown that mass incarceration has wide reaching effects on health and mortality. However, the impact of mass incarceration on broader emotional and social wellbeing has not been closely studied. The aim of this study is to assess how exposure to the criminal justice (CJ) system is associated with wellbeing.

METHODS: We used data from the 2018 FamHIS study, a nationally representative cross-sectional study of incarceration among family members (N=2815). Of 4,401 who completed the screening about family incarceration, 1,806 individuals with- and 1,009 without- family incarceration experience were included in the study. CJ exposure was classified by each individual's highest level of personal CJ contact: none, stopped by police, stopped and frisked, arrested, incarcerated, or incarcerated multiple times. We measured wellbeing using the 100 Million Healthier Lives Adult Wellbeing Assessment, a set of validated items that measures thriving or suffering within five domains of wellbeing: physical health, mental health, social wellbeing, spiritual wellbeing, and overall life evaluation. We report frequencies of thriving and suffering at each level of CJ contact, and use logistic regression to compare wellbeing across CJ exposure levels, controlling for confounding by age, gender, race, income, housing type, employment status, education, and marital status.

RESULTS: Compared to those without personal CJ exposure (N=1,575), any CJ exposure (N=1,229) was associated with lower rates of thriving (74% vs 61%, p<0.001) and higher rates of suffering (4% vs 8%, p=<0.001). Across all five domains of wellbeing, there was a progressive decrease in thriving and increase in suffering with increasing exposure to the system (table, p<0.001 for each trend). In adjusted models, a strongly decreased odds of overall thriving was only seen in those with any police stop (AOR 0.59, 95% CI 0.41 - 0.87) or any incarceration (AOR 0.59, 95% CI 0.4 - 0.85), compared to those without CJ exposure.

CONCLUSIONS: Increasing exposure to the criminal justice system is associated with a dose dependent decrease in wellbeing in every domain. This highlights the need for clinical interventions in diversion and CJ reform to not only focus on incarceration, but also on reducing police contact to achieve population-level improvements in health.

Figure. Average weight loss adjusted for demographic and health care utilization characteristics for the PSMF and Control diet participants

ASSESSING WHEN TO STOP OR SCALE BACK ROUTINE MEDICAL SERVICES: THE ASSURES STUDY

Eve A. Kerr^{1, 2}; Mandi L. Klamerus¹; Adam Markovitz^{1, 2}; Tanner Caverly^{1, 2}; Jeremy Sussman^{1, 2}; Sameer D. Saini^{1, 2}; Lillian Min^{1, 2}; Steven J. Bernstein²; Roger Chou³; Shannon E. Lohman^{1, 4}; Whit Froehlich^{1, 2}; Sarah E. Skurla¹; David E. Goodrich¹; Timothy Hofer^{1, 2}. ¹VA Center for Clinical Management Research, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³Oregon Health and Science University, Portland, OR; ⁴Wayne State University, Detroit, MI. (Control ID #3184286)

BACKGROUND: Recommendations in current guidelines primarily focus on intensifying medical services. While Choosing Wisely (CW) has encouraged specialty groups to develop recommendations about overuse, to date no one has developed a systematic approach to identifying and validating recommendations for stopping or scaling back (de-intensifying) tests or treatments. We designed such an approach and applied it to a set of common ambulatory conditions.

METHODS: The identification of candidate recommendations for de-intensification began with a systematic scan of guidelines/recommendations developed by selected specialty societies, the USPSTF, and CW. We limited our search to the following common clinical areas in routine ambulatory primary care: prevention and treatment of cardiovascular disease (CVD) and diabetes (DM), screening (non-CVD), and inappropriate medication use in adults. Each candidate recommendation was reviewed by physician investigators to: 1) verify it related to de-intensification and was relevant to routine primary care; 2) assess whether it would likely improve outcomes, impact patients, and be feasible to measure. An external advisory council prioritized the resultant recommendations. The prioritized recommendations, and supporting evidence, were considered by two multidisciplinary expert panels of physicians. Panel 1 (N=13 members) had expertise in CVD and DM; Panel 2 (N=12 members) had expertise in screening and medication use. We adapted the RAND/UCLA Appropriateness Method of two rounds of ratings with discussion between by employing virtual group participation via an internet collaboration tool plus teleconferences. The primary rating criterion was validity (1-9; 9=recommendation definitely based on high-quality scientific evidence). The recommendations were classified according to the panel's median final rating and level of disagreement among panelists.

RESULTS: The systematic scan resulted in 947 potentially relevant recommendations. 538 were excluded by physician investigators as not meeting study criteria. 409 were grouped into 178 similar recommendations, with 37 prioritized by the advisory council. Following refinements to the recommendations, the two expert panels rated 44 de-intensification recommendations. 37 (84%) were rated as valid (median validity rating between 7-9) without substantial disagreement. Recommendations classified as appropriate

included: CVD (N=10; e.g., stop carotid artery stenosis screening in asymptomatic patients); DM (N=4; e.g., reduce DM medications in patients at high-risk for hypoglycemia); screening (non-CVD) (N=13, e.g., don't screen for breast cancer in women with a limited life expectancy); and medication use (N=10; e.g., decrease benzodiazepines in older adults).

CONCLUSIONS: Recommendations for de-intensifying medical care can be systematically developed and validated using evidence curated by existing guideline efforts. These findings set the stage for planning implementation approaches to stop or scale back unnecessary services.

ASSESSMENT OF INTERNAL MEDICINE RESIDENT PREPAREDNESS TO CARE FOR LESBIAN, GAY, BISEXUAL, TRANSGENDER, AND QUEER/QUESTIONING PATIENTS

Carl G. Streed¹; Helene F. Hedian²; Amanda Bertram²; Stephen Sisson².

¹Boston Medical Center, Boston, MA; ²Johns Hopkins University, Lutherville, MD. (Control ID #3148706)

BACKGROUND: Recognizing the unique health needs of sexual and gender minorities (i.e. lesbian, gay, bisexual, transgender, queer/questioning individuals) is critical to providing competent and comprehensive health care. We aimed to assess resident knowledge of health care issues uniquely affecting sexual and gender minorities as well as the role of online case-based didactics to measure and improve knowledge in the diagnosis and treatment of these patients.

METHODS: We designed a multicenter online education intervention from December 2016 to April 2018. The study population consisted of 833 PGY1-3 residents at 120 internal medicine residency programs in the United States who completed 1018 tests. We developed a one-hour online module addressing sexual and gender minority (SGM) health. The test evaluated each resident in four categories: 1) terminology relevant to SGM patients; 2) health disparities and preventive care issues affecting SGM patients; 3) substance use and mental health issues unique to SGM patients; and 4) common sexually transmitted illnesses affecting SGM populations. Participants completed a pretest assessing sexual and gender minority (SGM) health knowledge. A didactic module reviewing diagnosis and management of these diseases was then completed, followed by a posttest.

RESULTS: Among 1018 resident responses, there was no difference between post-graduate year pre-test performance (PGY-1 52%, PGY-2 50%, PGY-3 51%; p = 0.532) or post-test performance (PGY-1 80%, PGY-2 82%, PGY-3 82%; p = 0.285). Pre-test and post-test performance of an online didactic module was the same across test categories and patient populations for PGY-1 vs. PGY-2 vs. PGY-3. Residents demonstrated an improvement between pre- and post-test knowledge.

CONCLUSIONS: Baseline knowledge of health issues of sexual and gender minorities, as assessed by pre-test performance, did not change during residency training. An online didactic module introduced trainees to critical issues regarding the care of these vulnerable populations until such curricula are required in training. Health disparities in LGBTQ communities may improve with improved physician training on clinical care of LGBTQ patients and families.

ASSOCIATION BETWEEN ANTIBIOTIC USE AND ACUTE KIDNEY INJURY IN PATIENTS HOSPITALIZED WITH COMMUNITY-ACQUIRED PNEUMONIA

Phuc H. Le¹; Pei-Chun Yu¹; Preethi Patel²; Andrei Brateanu²; Peter Imrey¹; Michael B. Rothberg¹. ¹Cleveland Clinic, Cleveland, OH; ²CCF, Cleveland, OH. (Control ID #3185606)

BACKGROUND: Acute kidney injury (AKI) is common during hospitalization for community-acquired pneumonia (CAP) and may be associated with specific antibiotics. The risk of AKI associated

with vancomycin and piperacillin-tazobactam have been reported, but the association with other antibiotic classes is unknown. We aimed to estimate and compare the risk of AKI for various antibiotic combinations in a large sample of adults hospitalized for CAP.

METHODS: The study was a retrospective cohort analysis of the Premier Healthcare Database containing all admissions for 660 US hospitals from 2010-2015. We included adults aged 18 years hospitalized with CAP, defined as either a principal ICD-9 code of pneumonia or a principal diagnosis of sepsis or respiratory failure and a secondary code of pneumonia. We considered 8 different antibiotic combinations based on continuous use in the first 3 hospital days. Primary outcome was AKI, defined by ICD-9 codes 584.X. We excluded patients who were admitted to the ICU any time during hospitalization, had AKI codes documented on admission, or had dialysis in the first 2 days. We used mixed logistic regression with hospital as a random effect and adjusted for patient demographics, comorbidities, other treatments on day 0/1, and hospital characteristics.

RESULTS: The total sample included 418,408 patients, 1.2%-3.6% of whom developed AKI. Compared to those without AKI, patients with AKI were older and more likely to be male, Black, and have Medicare, sepsis or aspiration pneumonia as principal diagnosis, and immune suppression. Patients with AKI also had a higher rate of in-hospital dialysis (2.4% vs. 0%), discharge to hospice (8.6% vs. 4.1%), longer median length of stay (7 vs. 4 days) and higher mortality (12% vs. 2.4%). Compared to a macrolide plus 3rd generation cephalosporin, all other combinations except quinolones were positively associated with developing AKI. The combination of piperacillin/tazobactam and vancomycin with or without quinolones was associated with the highest odds ratio (OR, 95% CI: 2.55 (2.29- 2.83) and 2.46 (2.23- 2.72) respectively).

CONCLUSIONS: Broad spectrum antibiotics were associated with a higher odds of developing AKI compared to narrow spectrum regimens. The choice of empiric regimens for patients hospitalized with CAP should take into account this potential complication.

ASSOCIATION BETWEEN BURNOUT AND INTELLIGENCE MINDSET IN INTERNAL MEDICINE TRAINING PHYSICIANS

Justin Chen¹; Angela Fink²; Regina F. Frey²; Erin Solomon²; Stephen Fuest¹; Rakhee Bhayani¹; Patricia Kao¹. ¹Washington University in St. Louis School of Medicine, St. Louis, MO; ²Washington University in St. Louis, St. Louis, MO. (Control ID #3180399)

BACKGROUND: Carol Dweck's theory of intelligence differentiates learners as individuals who characterize intelligence as a trait that can be increased through effective practice and perseverance (growth mindset) or one that is immutable and pre-determined (fixed mindset). Studies show that curriculums promoting a growth mindset have improved the academic performance of elementary to college learners, but its effect on graduate medical education is still not defined. This study aims to characterize the intelligence mindset of internal medicine (IM) residents, identify demographic risk factors associated with intelligence mindset, and ascertain if growth mindset education reduces burnout scores.

METHODS: This is a randomized control trial to study a four-phase educational intervention for IM residents at Washington University in St. Louis School of Medicine/Barnes-Jewish Hospital from 6/2018-6/2019. IM residents were randomized to receive an educational intervention on general wellness (control) or growth mindset (experimental). Participants will complete a survey including demographics, burnout risk factors, burnout measured by the Maslach Burnout Inventory (MBI) subscales, and intelligence

mindset measured by the Theories of Intelligence Scale (TIS) and Mindset Assessment Profile (MAP) before and after the intervention.

RESULTS: 55% (86/155) of all IM residents and 100% (52/52) of post-graduate year one residents participated in the first phase of the study. The proportion of fixed, indeterminate, and growth mindset were respectively 30.2%, 10.5%, and 59.3% by the TIS and 7%, 62.8%, and 30.2% by the MAP. There is a significant negative correlation between MAP and both the MBI emotional exhaustion ($p=0.006$) and depersonalization ($p=0.05$) scores and a positive correlation between MAP and MBI personal achievement scores ($p=<0.001$). The TIS was found to have a positive correlation with MBI personal achievement scores ($p=0.04$). Among the postgraduate year one residents, individuals from underrepresented minority groups were more likely to have a fixed mindset using the TIS ($p=0.05$).

CONCLUSIONS: There are approximately twice as many IM resident physicians with a growth mindset compared to a fixed mindset using the TIS and only 30% of IM residents carry a growth mindset using the MAP. MAP scores showed that residents with growth mindsets tended to report less burnout reflected by less emotional exhaustion and depersonalization and a greater sense of personal achievement. TIS scores were less sensitive to these associations but yielded consistent results. This study identifies a population of physicians where a growth mindset education may reduce burnout rates. If this curriculum is effective in reducing burnout, it may also reduce the consequences of burnout on physician performance, patient satisfaction, and healthcare utilization.

ASSOCIATION BETWEEN HIGH DEDUCTIBLE HEALTH PLANS AND COST-RELATED NON-ADHERENCE TO MEDICATIONS AMONG PEOPLE WITH DIABETES: A NATIONAL STUDY

John Gaudet²; Charlotte Rastas¹; Ariel Majidi¹; Drew Bunker²; Jaeyoung Yang¹; Shirin Karimi¹; Vikas Gampa²; Laura Trueman¹; Adam Gaffney¹; Gaurab Basu¹; Danny McCormick¹. ¹Cambridge Health Alliance, Harvard Medical School, Boston, MA; ²Cambridge Health Alliance, Cambridge, MA. (Control ID #3185828)

BACKGROUND: Prices of diabetes medications, particularly insulin, have risen substantially in recent years. High-deductible health plans (HDHP), which require high out of pocket payments before coverage begins, have recently become the predominant type of commercial insurance. However, the impact of HDHPs on cost-related medication non-adherence (CRNA) among adults with diabetes nationally is not known.

METHODS: We analyzed data from the 2011 to 2017 National Health Interview Survey, a nationally representative survey of non-institutionalized adults in the United States. The study sample included privately insured adults age 18-64 with diabetes who were enrolled in either a HDHP or a traditional commercial health plan (THP). CRNA was assessed with 4 questions that asked if an individual 1) could not afford medication, or 2) skipped doses3) took less medicine or 4) delayed filling a prescription, in order to save money. We assessed the association between enrollment in an HDHP (vs. a THP) and each individual measure of CRNA as well as a composite measure (any individual measure) using multivariable linear probability models that controlled for age, sex, family size, race/ethnicity, marital and health status, functional limitation, education, income and employment status. We also assessed whether any CRNA was associated with 1 or more emergency room visits or hospitalization in the past year. Analyses were stratified by whether the individual reported insulin use.

RESULTS: Baseline demographic and health status indicators were similar between the 4,325 THP and 2,270 HDHP enrollees. Among those not taking insulin, HDHP enrollees were more likely than THP enrollees to: not fill a prescription (13.0% vs 9.1%, respectively; adjusted percentage point difference (AD), 3.6 [95% CI, 1.0- 6.1]); skip medication doses (10.6% vs 8.1%; AD, 2.5 [95% CI, 0.1 - 4.9]); and to have any type (combined measure) of CRNA (19.2% vs 15.0%; AD, 3.5 [95% CI, 0.5 - 6.6]). Higher percentages of enrollees in HDHPs also took less medication or

delayed filling a prescription but these differences did not reach statistical significance. Among those taking insulin, 18% of THP and 25.3% of HDHP enrollees had any type of CRNA (AD, 6.1 [95% CI, 1.0 -11.2]). Higher percentages of enrollees in HDHPs (vs THP) also reported CRNA for each individual measure but these did not reach statistical significance. Among those taking insulin, those reporting any CRNA were more likely to have at least 1 emergency department visit (44.1% vs 24.2%, respectively; AD, 13.8 [95% CI, 6.6 -21.0]) or hospitalization in the last year (28.1% vs 16.3%, AD, 7.1 [95% CI, 0.9 - 13.4]).

CONCLUSIONS: Nationally, HDHPs are associated with greater CRNA among people with diabetes, particularly those taking insulin. Lowering or eliminating deductibles, and lowering the price of insulin, could reduce CRNA among people with diabetes, and potentially reduce adverse outcomes of CRNA.

ASSOCIATION BETWEEN MORTALITY AND FREQUENCY AND LIFETIME SPENT INCARCERATED AMONG US VETERANS WITH HIV

Laura Hawks^{2, 1}; Kathleen A. McGinnis³; Benjamin A. Howell⁴; Maria R. Khan⁵; E. Jennifer Edelman⁴; Amy C. Justice⁶; Emily A. Wang⁴. ¹Harvard Medical School, Boston, MA; ²Cambridge Health Alliance, Cambridge, MA; ³VA Pittsburgh Healthcare System, West Haven, CT; ⁴Yale School of Medicine, New Haven, CT; ⁵New York University School of Medicine, New York, NY; ⁶Yale University, New Haven, CT. (Control ID #3180733)

BACKGROUND: Exposure to incarceration is associated with greater risk of mortality, especially following release from correctional facilities. Few studies have examined whether frequency of incarceration or amount of time spent incarcerated over one's lifetime is associated with increasing mortality. We used data from the Veterans Aging Cohort Study (VACS) to compare mortality by intensity of incarceration exposure among individuals with HIV.

METHODS: HIV+ participants who provided a response to incarceration questions in the VACS survey from January 2011 to August 2017 were included (N=2,718), and mortality data were available through August 2018. We calculated and compared mortality rates per 100 person years (pys) by three incarceration measures: 1) ever/never; 2) number of times over lifetime; and 3) length of time over lifetime. We then used Cox Proportional Hazard models to determine whether the three incarceration measures are associated with increased mortality adjusting for demographics (race, sex, age), and then also adjusting for social and health-related factors (education, smoking, HCV, social support, hazardous drinking, and homelessness, past year drug use, and mental health disorders).

RESULTS: Participants' mean age was 56, ranging from 22 to 84; 66% were African-American, 19% white, and 9% Hispanic or other; 97% were male, 38% reported current cigarette smoking, 36% were HCV+, 55% reported exposure to incarceration. There were 465 mortality events over a mean follow-up time of 5.8 years. Unadjusted mortality rates increased with incarceration exposure for all three incarceration measures and were 2.7 per 100 person years (pys) for those never incarcerated vs 3.6 for those ever incarcerated. In models adjusted for demographics, ever incarceration was associated with an AHR of 1.36 [1.13-1.66]. Number of times incarcerated was associated with mortality in models adjusted for demographics with AHRs of: 1.1 [0.9-1.5], 1.45 [1.2-1.8], and 1.64 [1.2-2.2] for 1, 2-5; 6+ times, respectively. Length of time incarcerated was also associated with mortality in models adjusted for demographics with AHRs of: 1.1 [0.9-1.5], 1.4 [1.1-1.9], 1.6 [1.2-2.2], and 1.6 [1.1-2.2] for <1 month, 1 to 11 months, 1-5 years, and >5 years, respectively. After further adjustment for social and health-related factors, the associations were no longer statistically significant.

CONCLUSIONS: Among individuals living with HIV, increasing exposure to incarceration (both frequency and total length of time spent incarcerated) was associated with increased mortality in unadjusted analyses and models adjusting for demographics. However, this association was not seen after additional adjustment for social and health-related factors, suggesting some covariates may be mediators or confounders.

ASSOCIATION BETWEEN NEOPLASTIC MENINGITIS AND BIOLOGIC FALSE-POSITIVE CSF-VDRL

Terin Sytsma; Elitza Theel; Zelalem Temesgan; Michel Toledano. Mayo Clinic, Rochester, MN. (Control ID #3183048)

BACKGROUND: Neurosyphilis should be considered in patients with encephalopathy, chronic meningitis, and progressive cranial neuropathies. While there is no gold standard diagnostic test for neurosyphilis, the cerebrospinal fluid venereal disease research laboratory (CSF-VDRL) is considered highly specific for the disease. Neoplastic meningitis has been a rarely reported cause of false-positive CSF-VDRL, but the frequency is unknown. This study sought to quantify the rate and determine the cause(s) of CSF-VDRL false-positivity.

METHODS: This retrospective chart review of all CSF-VDRL testing in patients presenting to a tertiary care center between January 1, 1994 and February 28, 2018 assessed the rate of false-positive CSF-VDRL results and underlying condition(s) in patients with falsely reactive CSF-VDRL. Demographic and clinical information for all false-positive CSF-VDRL cases were summarized. Descriptive statistics were used to calculate rates of positive, true-positive and false-positive CSF-VDRL results.

RESULTS: Among 34,336 CSF-VDRL tests performed, 66 (0.19%) were positive. Of 66 positive CSF-VDRL tests, 50 (75.8%) were true-positives and 16 (24.2%) were false-positives. Fourteen individual patients had a false-positive CSF-VDRL result: nine males, five females, ranging in age from 14 to 82 years old. None had positive serologic syphilis testing. Nine of 14 patients with false-positive CSF-VDRL results (64.3%) had neoplastic meningitis: six (42.9%) from metastatic carcinoma (five primary lung cancers and one esophageal cancer), two (14.3%) from astrocytoma with meningeal involvement, and one (7.1%) from lymphomatosis. Four of the 14 patients with false-positive testing had a repeat CSF-VDRL; two were repeatedly positive, and both of these had meningeal carcinomatosis due to metastatic lung carcinoma. The two patients with negative repeat CSF-VDRL did not have neoplastic meningitis.

CONCLUSIONS: A majority of patients with false-positive CSF-VDRL testing in this study were ultimately diagnosed with neoplastic meningitis. Neoplastic meningitis is a frequent cause of false-positive CSF-VDRL results, and should be considered in patients with a positive CSF-VDRL but negative syphilis serology. The VDRL assay detects antibodies, including cardiolipin, and anticardiolipin antibodies have been reported in lung and central nervous system malignancies. Thus it is possible that the CSF-VDRL assay reacts with these antibodies. The two patients in this study with positive repeat CSF-VDRL testing had meningeal carcinomatosis, further suggesting that the false-positive CSF-VDRL test in patients with neoplastic meningitis represents a biologic false-positive. All patients with false-positive CSF-VDRL results in this study had negative serologic testing for syphilis, but serologic testing was not always available prior to CSF-VDRL results. This highlights the importance of considering pretest probability when ordering and interpreting CSF-VDRL testing.

ASSOCIATION BETWEEN OVERALL MATERNAL HEALTH STATUS AND FAMILY RESILIENCE: RESULTS FROM A NATIONAL SURVEY

Sitara Soundararajan¹; Shyla Jagannatha²; Jaya Aysola³. ¹Drexel University College of Medicine, Philadelphia, PA; ²Janssen Research & Development, Raritan, NJ; ³University of Pennsylvania, Philadelphia, PA. (Control ID #3138305)

BACKGROUND: The relationship between maternal health and health outcome of offspring has been studied extensively. However, there is sparse data available regarding the association between overall maternal health and the health, functionality, and productivity of the *family* unit. More specifically, measures such as family resilience in the context of

maternal health are not well understood. The objective of this study was to determine if overall maternal health status is associated with family resilience.

METHODS: We analyzed data from the 2016 National Survey of Children's Health (NSCH), the only national survey assessing the health of children ages 0-17 in the United States. The independent variable in this study was overall physical and mental maternal health status. The main outcome of interest was presence of family resilience. Other outcomes of interest for this study included parental aggravation and adverse childhood experiences. We estimated the association between maternal health status and family resilience with a multivariate logistic regression model, adjusting for the following covariates: current health insurance status, family structure of child's household, child race, highest education of adult in household, income level, and primary household language.

RESULTS: Compared to mothers whose physical and mental health are not excellent or very good, mothers who had excellent or very good physical and mental health statuses have families that showed significantly better adjusted rates for family resilience measures. Results suggest that mothers with excellent or very good physical and mental health have higher odds of having families that exhibit resilience [adjusted odds ratio (AOR) 2.790, CI [2.409, 3.231]], compared to mothers whose physical and mental health are not excellent or very good. Controlling for protective factors (e.g. supportive neighborhoods, emotional help with parenting) did not change the significance of the results [adjusted odds ratio (AOR) 2.617, CI [2.245, 3.051]]. Parental aggravation and adverse childhood experiences were also identified as possible mediators of the relationship between overall maternal health status and family resilience.

CONCLUSIONS: The study's results indicate that improved maternal health status is associated with higher odds of family resilience, even after adjusting for potential confounders. These findings suggest that overall maternal health may have a unique role in shaping the way families respond to adversity. Interventions addressing the health of our nation's mothers may have potential in improving the manner in which US families withstand and rebound from adversity.

ASSOCIATION BETWEEN PARTICIPATION IN BUNDLED PAYMENTS FOR MEDICAL CONDITIONS AND CHANGES IN SPENDING AND UTILIZATION: A 3-YEAR ANALYSIS OF THE BUNDLED PAYMENTS FOR CARE IMPROVEMENT INITIATIVE

Joshua Rolnick²; Joshua M. Liao^{1, 2}; Xinshuo Ma²; Ezekiel J. Emanuel²; Eric Z. Shan²; Jingsan Zhu²; Erkuan Wang²; Qian Huang²; Amol S. Navathe^{3, 2}. ¹University of Washington, Seattle, WA; ²University of Pennsylvania, Philadelphia, PA; ³CMC VA Medical Center, Philadelphia, PA. (Control ID #3182757)

BACKGROUND: Bundling payments for an episode of care have shown savings for lower joint replacement surgery, but are less well-studied for medical conditions. An early investigation of Medicare's Bundled Payments for Care Improvement (BPCI) initiative examined five medical conditions, finding no changes in spending or utilization after a mean seven months of follow up. We extend this work with longer-term data and different model specification to investigate BPCI participation for four high-volume conditions: congestive heart failure (CHF), pneumonia, acute myocardial infarction (AMI), and chronic obstructive pulmonary disorder (COPD).

METHODS: We performed a difference-in-differences analysis of episodes in 2011-2016 Medicare claims. Episodes attributed to BPCI physician groups were removed to avoid bias. BPCI participant hospitals were propensity-matched with up to 5 non-participants by condition. Outcomes included standardized total episode spending (primary) and spending by category, readmission rates, and mortality. Models were adjusted for patient and market characteristics, as well as hospital and quarter fixed effects. Ordinary least squares models were used for utilization and

generalized linear models with a log-link function and gamma distribution for spending.

RESULTS: From October 2013-January 2016, 185 hospitals joined the CHF bundle, 137 joined COPD, 145 joined pneumonia, and 97 joined AMI (238 total). 223 BPCI hospitals (293,899 baseline episodes, 92,801 treatment) were matched to 1,074 control hospitals (433,082 baseline episodes, 392,537 treatment). Mean follow-up per hospital-condition was 22 months. Baseline age and sex were similar across groups and the Elixhauser risk index was 20.3 BPCI vs. 19.3 controls ($p<0.001$). Total baseline spending was \$20,667 BPCI vs. \$19,799 controls ($p<0.001$). The parallel trends assumption was met. In adjusted analyses, BPCI participation was associated with a significant risk-adjusted total spending increase of 0.9% (95% CI 0.4%-1.4%, p -value<0.001) and an increase in physician fees of 1.2% (95% CI 0.6%-1.8%, p -value<0.001). There were non-significant increases of 1.6% (95% CI -0.6%-3.9%, p -value=0.16) for SNF and 1.5% (95% CI -0.6%-3.7%, p -value=0.17) for readmission spending. Participation was associated with significant increases of 0.3% (95% CI 0.01%-0.62%, p -value=0.04) in readmission rate and 0.4% (95% CI 0.08%-0.62%, p -value=0.01) in SNF discharges. Mortality was unchanged.

CONCLUSIONS: Contrary to program expectations, BPCI participation was associated with an increase in total spending, likely due to increases in physician fees. Readmissions increased. Bundled payment programs for medical conditions may not achieve the intended effects and may even cause harm. While further work is needed, these findings may caution policymakers given the new BPCI-Advanced program.

ASSOCIATION BETWEEN THE USE OF CLINICAL DECISION SUPPORT AND PERFORMANCE ON QUALITY MEASURES BY PRIMARY CARE PROVIDERS: EVIDENCE FROM THE MEANINGFUL USE AND PHYSICIAN QUALITY REPORTING SYSTEM PROGRAMS

Jorge A. Rodriguez¹; Jonathan E. Fried²; Stuart R. Lipsitz^{3, 2}; Adam B. Landman³; Lipika Samal^{3, 2}. ¹Lawrence General Hospital, Lawrence, MA; ²Harvard Medical School, Boston, MA; ³Brigham and Women's Hospital, Boston, MA. (Control ID #3185517)

BACKGROUND: Federal quality reporting programs stopped measuring the use of clinical decision support (CDS) after 2016. We sought to determine whether successful implementation of at least five CDS interventions, as reported to the Meaningful Use (MU) program, was correlated with higher quality of care, as measured by the Physician Quality Reporting System (PQRS).

METHODS: We obtained provider-level performance rates on eight process measures reported to PQRS in 2016 by 24,686 primary care providers (PCPs) from the Physician Compare Individual Eligible Professional (EP) Public Reporting data file. We used the MU Stage 2 EP Public Use File to assess their CDS use (defined as using 5 or more CDS; providers opted in). We then used logistic regression clustered by EP to assess the relationship between CDS use and performance on quality measures.

RESULTS: Only 31.7% of PCPs reported using CDS to fulfill MU requirements and 0.85% explicitly reported not using it. 67.45% did not report on this measure and were excluded. There was a significant positive association between CDS use and influenza vaccination. There was no statistically significant association between CDS use and rates of advance care plan use, avoidance of high-risk medications in the elderly, pneumococcal vaccination, documentation of current medications, tobacco cessation counseling, osteoporosis screening, or colorectal cancer screening.

CONCLUSIONS: Influenza vaccination rates were higher for providers that used CDS than for those who did not. We did not find associations for the other measures. However, EPs were not required to report on CDS and very few providers explicitly reported a lack of use, which limited our sample size. EPs were not asked to report which type of CDS they had

implemented. Elimination of CDS measures from pay for performance (P4P) programs such as the Promoting Interoperability Program may reduce incentives to invest in CDS for quality and safety. Further, our ability to draw meaningful conclusions are limited by the Centers for Medicare & Medicaid Services' (CMS) incomplete reporting of PQRS data. CMS should make complete, de-identified PQRS data available to identify ways to improve P4P programs.

ASSOCIATION OF ADHERENCE WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE AND COMORBID HYPERTENSION AND DIABETES MEDICATIONS

Grace McInerney¹; Rachel O'Conor³; Michael S. Wolf³; Juan Wisnivesky²; Alex Federman¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Mount Sinai School of Medicine, New York, NY; ³Northwestern University, Chicago, IL. (Control ID #3174967)

BACKGROUND: Non-adherence with chronic obstructive pulmonary disease (COPD) medications is common among older adults, but it is unknown whether COPD self-management behaviors are associated with adherence patterns to medications for comorbid conditions like hypertension or diabetes.

METHODS: To determine the association of COPD medication adherence with adherence to medications for comorbid illnesses, we performed a cross-sectional analysis of data collected from a cohort of COPD patients with comorbid hypertension or diabetes. A sample of 282 adults ages 40 years and older with COPD were recruited from primary care practices in New York, NY, and Chicago, IL. Medication adherence was measured using the Medication Adherence Rating Scale (MARS), a validated 10-item self-reported measure designed to minimize social desirability bias. Each item is rated on a 5-point Likert scale, with higher scores indicating greater adherence. Participants with a MARS score of 4.5 or greater were classified as having good adherence. We calculated the Pearson correlations for MARS scores for COPD and hypertension, COPD and diabetes, and hypertension and diabetes.

RESULTS: The mean age was 68 (SD 9), 59% were female, 38% were black and 17% were Hispanic; 95% were English language proficient. Overall, 98% of participants had comorbid hypertension and 35% diabetes; 33% of participants had both comorbid diabetes and hypertension. Adequate COPD medication adherence was reported by 53% of patients, 70% for hypertension medications, and 61% for diabetes medications. Medication adherence for COPD and hypertension medications ($r=0.43$, $P<0.0001$) and hypertension and diabetes medications ($r=0.43$, $P=0.0001$) were strongly correlated. However, adherence to COPD and diabetes medications ($r=0.12$, $P=0.29$) were not correlated.

CONCLUSIONS: Associations of medication adherence behaviors varied across different comorbidities. Understanding the underlying basis for different patterns of adherence to medications in different therapeutic classes may provide insight into new ways of facilitating self-management of medications among patients with multimorbidity.

ASSOCIATION OF CHRONIC PAIN AND MYOCARDIAL INFARCTION

Jigar J. Patel¹; Talal S. Alzahrani²; Shanelle Weerakoon²; William Borden². ¹George Washington University, Washington, DC; ²The George Washington University, Washington, DC. (Control ID #3142581)

BACKGROUND: Chronic pain affects many patients and is the primary reason for visits to primary care clinics and emergency departments. In previous studies, chronic pain has been linked to mortality and cardiovascular disease. This study further explores this

relationship by analyzing the association between chronic pain and myocardial infarction using a national database.

METHODS: The National Health Interview Surveys of 2017 (n=26,445) were used to examine the cross-sectional association between frequency of pain (never, some days, most days, every day) and myocardial infarction in a single logistic regression model that also included demographics [age, gender, Body Mass Index (BMI)] and health characteristics (smoking, hypertension, diabetes, hypercholesterolemia and exercise).

RESULTS: Participants who reported having pain every day were more likely to be female (60% vs. 52%) and older (61 vs. 49 years) than participants who reported never having pain. The rates of daily smoking (23% vs. 9.6%), diabetes (24.9% vs. 8%), hypertension (63.1% vs. 29.2%), hypercholesterolemia (50.4% vs. 27.4%), and myocardial infarction (10.9% vs. 2.6%) were significantly higher in participants who reported having pain every day compared to subjects who reported never having pain. The logistic regression model showed that reporting daily experience of pain was independently associated with increased odds of having had a myocardial infarction ($OR=2.19$, 95% CI 1.69, 2.83, $p <0.001$) as was experience of pain most days ($OR = 2.08$, 95% CI 1.49-2.91, $p <0.001$), and experience of pain some days ($OR = 1.51$, 95% CI = 1.24-1.83, $p <0.001$) compared to never having pain after adjusting for demographics and health characteristics.

CONCLUSIONS: The frequency of chronic pain is significantly associated with the rate of myocardial infarction after adjusted for cardiovascular risk factors including age, gender, BMI, hypertension, diabetes, hypercholesterolemia, and lack of exercise. Future studies are needed to evaluate the efficacy of managing pain in reducing myocardial infarction.

ASSOCIATION OF E-CIG USE AND NON-PRESCRIBED MEDICATION USE: RESULTS FROM THE PATH SURVEY

Eric Mortensen; Nkiruka Atuegwu; Kathryn Bentivegna; Mario F. Perez; Cheryl Oncken. UConn Health, Farmington, CT. (Control ID #3177619)

BACKGROUND: Use of electronic cigarettes ("e-cigs") is increasing in the US, but little is known about their association with other high-risk behaviors. The purpose of this study was to examine the association between e-cig use and a participant's report of the use of pain killers, sedatives, or tranquilizers that were not prescribed to them, within a nationally representative sample of adults.

METHODS: We used the waves 1-3 of the Population Assessment of Tobacco and Health (PATH) survey adult data (N=23,670). We defined current e-cig use as daily or some days use of e-cigs by participants in wave 1. We then used logistic regression to examine the association between current e-cig use and the use of non-prescribed pain killers, sedatives, or tranquilizers in the last 30 days, or 12 months, after adjusting for the covariates including demographics (age, gender, marital status, income, prior education), use of combustible tobacco and other nicotine products, use of illicit drugs, and psychiatric symptoms. Replicate weights and balanced repeated replication methods were utilized to account for the complex survey design.

RESULTS: We compared the 2,639 current e-cig users to the 21,024 non-users. After adjusting for the potential confounders, the use of e-cigs is associated with significantly higher use of non-prescribed pain killers, sedatives, or tranquilizers in the last 30 days (odds ratio [OR] 1.30, 95% confidence interval [CI] 1.14-1.48) and last 12-months (OR 1.31, 95% CI 1.15-1.49).

CONCLUSIONS: Our findings demonstrate that e-cig users have significantly higher odds of non-prescription use of pain killers, sedatives, or tranquilizers in the future. Clinicians should be aware

of this association and screen for the inappropriate use of prescription medications in their patients who regularly use e-cigs.

ASSOCIATION OF HEALTHCARE TRUST AND DISCRIMINATION WITH SCREENING FOR VIOLENCE AND GUN OWNERSHIP IN CLINICAL SETTINGS

Madison R. Wilson; Monica E. Peek; Nichole Smith; Tyrone A. Johnson; Elizabeth L. Tung. University of Chicago, Chicago, IL. (Control ID #3184488)

BACKGROUND: Growing political discord over gun violence in the U.S. has resulted in national conversations about the role of healthcare in screening for violence and gun ownership. While some states have enacted laws limiting physicians' ability to screen patients for gun ownership, multiple medical associations encourage physicians to implement routine screening practices. However, few studies have documented the extent to which healthcare providers are implementing screening practices; and fewer have examined the relationship between these types of screening practices and patient-oriented outcomes, such as healthcare trust and perceived healthcare discrimination.

METHODS: We recruited a sample of 506 adult patients, ages 35 years, from 2 medical clinics on the South and West Sides of Chicago. Surveys were administered using Computer-Assisted Personal Interviewing software on tablets. Healthcare relationship trust (HCR Trust Scale) and discrimination in medical settings (DMS Scale) were measured using validated items and normalized to 100-point scales. Healthcare screening for (1) community violence and (2) gun ownership/safety were measured using items adapted from national surveys ("Have you ever discussed [community violence / gun ownership or safety] with your physician or another health care professional?"). We used generalized linear regression models to independently assess HCR Trust and DMS scores as functions of healthcare screening items, adjusting for age, gender, race/ethnicity, education, insurance, and employment status.

RESULTS: The cooperation rate (COOP2) was 61%. The mean age of participants was 60 years (SD 13.0); the majority were female (71%) and black (75%). Although many (62%) had completed some college, almost two-thirds were unemployed (64%). Few patients (15%) had ever discussed community violence with a healthcare provider; even fewer (5%) had ever discussed gun ownership or safety. Mean HCR Trust was 78.1 ± 17.7 and mean DMS was 5.2 ± 1.2 (100-point scale). While screening for community violence was associated with a 5.1% higher HCR trust score (95% CI, 0.1 to 10.1), screening for gun ownership/safety was not associated with higher HCR trust. Conversely, while there was no association between screening for community violence and DMS scores, screening for gun ownership/safety was associated with a 6.8% higher DMS score (95% CI, 1.4 to 12.2), compared to those who had not been screened.

CONCLUSIONS: While screening patients for exposure to community violence was associated with higher healthcare trust, screening for gun ownership/safety was not, and may even be associated with perceptions of healthcare discrimination. As healthcare systems begin to consider screening for gun ownership/safety, implementation in low-income, minority settings should be cognizant of historically unfair targeting and profiling of residents.

ASSOCIATION OF MEDICARE SKILLED NURSING FACILITY COPAYMENTS WITH HIGHER DISCHARGE RATES OF ETHNIC MINORITIES AND SOCIOECONOMICALLY VULNERABLE PATIENTS

Paula Chatterjee¹; Mingyu Qi¹; Norma B. Coe¹; R Tamara Konetzka³; Rachel M. Werner². ¹University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania and Philadelphia VA, Philadelphia, PA; ³University of Chicago, Chicago, IL. (Control ID #3185721)

BACKGROUND: Medicare fully pays for post-acute care provided by skilled nursing facilities (SNFs) for the first twenty days within a benefit period. However, on the twenty-first day, patients become responsible for a daily copayment of over \$150. This may represent a significant financial burden for some patients, motivating discharge from SNFs based on finances rather than recovery. SNFs may also prematurely discharge some patients to avoid the risk of providing partially uncompensated post-acute care and bad debt. However, patterns of SNF discharge as they relate to these Medicare payment policies are unknown.

METHODS: We performed a retrospective cohort study of Medicare beneficiaries continually enrolled in fee-for-service Medicare with acute care hospital stays resulting in discharge to SNF from 2012-2016. For each SNF discharge, we computed the SNF benefit day on discharge based on the number of SNF benefit days used in that benefit period. We compared patient characteristics across benefit days, including age, sex, race/ethnicity, a count of 31 Elixhauser comorbidities, and ZIP-code-level socioeconomic status (from the American Community Survey), including median household income, poverty rate and unemployment rate. We compared differences using two-tailed t-tests

RESULTS: More patients are discharged from SNF on day 20 compared to days 19 or 21 (2.93% on day 19, 5.01% on day 20, and 2.69% on day 21). Patients discharged from SNF on benefit day 20 were younger (79.0 years among patients discharged on day 20 compared to 80.0 years on day 19 and 81.3 on day 21, $p<0.01$). They were also more likely to be Black/Hispanic (12.6% on day 20 compared to 8.1% on day 19 and 7.5% on day 21, $p<0.01$), and live in areas of high poverty (15.3% on day 20 compared to 13.8% on day 19 and 13.4% on day 21, $p<0.01$) with lower median household incomes (\$56,586 on day 20 compared to \$60,443 on day 19 and \$61,619 on day 21, $p<0.01$).

CONCLUSIONS: Medicare beneficiaries are more commonly discharged from SNFs on benefit day 20 than days 19 or 21, and those discharged on day 20 are more likely to be racial/ethnic minorities and of lower socioeconomic status compared to beneficiaries discharged either before or after benefit day 20. SNFs may be preferentially discharging vulnerable patients to avoid the risk of assuming responsibility for defaulted payments. Whether these practices impact patient outcomes remain unknown, but nonetheless raises concerns about the implications of this practice.

ASSOCIATION OF NUMBER OF UNIQUE HOSPITALISTS AND WORKLOAD WITH PATIENT OUTCOMES: AN ADMINISTRATIVE DATA ANALYSIS ACROSS 4 HOSPITALS

Henry J. Michatalik^{1, 2}; Peter J. Pronovost²; Jill A. Marsteller^{1, 3}; Joanne E. Spetz⁴; Daniel E. Ford^{2, 3}; Eric Howell^{1, 2}; Daniel Brotman². ¹Johns Hopkins Medicine, Baltimore, MD; ²School of Medicine, Johns Hopkins University, Baltimore, MD; ³Johns Hopkins School of Public Health, Baltimore, MD; ⁴University of California, Los Angeles, San Francisco, CA. (Control ID #3180462)

BACKGROUND: Hospitalists play a central role in patient care but little research has considered whether their workload or handoffs affect care quality. This study examined the impact of hospitalist workload and number of unique hospitalists involved in the patient's care on quality of care and patient communication.

METHODS: Measured in 4 hospitalist programs within a regional healthcare network, the main outcome was hospitalist workload averaged over a patient's hospitalization as determined from billing data. For example, if a patient had a 2-day hospitalization and was seen by a hospitalist with 12 patients day 1 and a different hospitalist with 14 patients day 2, the average workload the patient was exposed to was 13 patients and 2 unique hospitalists. Adjusting by site, we used regression to analyze average workload and its association with all-cause 30-day readmissions, hospital-acquired conditions, in-hospital mortality, and the 3 HCAHPS physician communication questions. We adjusted for patient

demographics (age, race, sex), severity of illness (APR-DRG SOI; range 1-4), observed length of stay (LOS), percentage of weekdays, and number of hospitalists. We also examined the effect of number of unique hospitalists involved in the patient's care on outcomes.

RESULTS: We analyzed 26,661 admissions at 4 hospitals from July 1, 2016 to June 30, 2017. The median patient LOS was 3 days [interquartile range (IQR): 2, 5]. The patient population was 60% Caucasian, 28% African American, 53% female with median age of 67 years [IQR: 52, 80] and APR-DRG severity of illness 3 [IQR: 2, 3]. The median number of unique hospitalists was 2 [IQR: 2, 3] with workload of 11 patients per day [IQR: 8, 13]. All-cause 30-day readmissions, hospital-acquired conditions, and in-hospital mortality were 13.2%, 1.4% and 1.2% respectively. We found no significant association between hospitalist workload and readmissions, in-hospital mortality, or patient communication after adjustment. Counterintuitively, a higher workload was associated with a lower odds of hospital-acquired condition ($p<0.001$). In contrast, even a small increase in the number of unique attending hospitalists increased the odds of having a hospital-acquired condition (OR: 1.23; 95% CI: 1.14, 1.34; $p<0.001$). The odds of patients reporting that the hospitalist carefully listened or clearly explained care also significantly decreased ($p<0.01$, $p<0.05$ respectively).

CONCLUSIONS: There was no significant association between hospitalist workload and the outcomes, except for hospital-acquired conditions. In contrast, increased number of unique hospitalists was associated with an increase in odds of a hospital-acquired condition and adversely affected listening and understanding. This suggests that transitions of care and communication, not necessarily workload, are associated with some adverse outcomes. Potential practice interventions to mitigate this may include standardizing handoffs and communication, and improving continuity with longer scheduling blocks.

ASSOCIATION OF PRIMARY CARE CLINIC APPOINTMENT TIME WITH CLINICIAN ORDERING AND PATIENT COMPLETION OF BREAST AND COLORECTAL CANCER SCREENING

Esther Y. Hsiang^{2, 3}; Shivan Mehta^{2, 1}; Dylan Small²; Charles Rareshide²; Christopher K. Snider²; Susan C. Day²; Mitesh Patel^{2, 1}. ¹Crescenz VA Medical Center, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA; ³Johns Hopkins Medical School, Philadelphia, PA. (Control ID #3139446)

BACKGROUND: Early cancer detection can improve clinical outcomes, but cancer screening rates in the United States are often suboptimal. As clinic days progress, primary care providers (PCPs) may fall behind schedule resulting in shorter rushed interactions with patients scheduled later in the day, and face increased decision fatigue. Our objective was to evaluate the association of primary care clinic appointment time with clinician ordering and patient completion of breast and colorectal cancer screening.

METHODS: We performed a retrospective analysis of 33 primary care practices in Pennsylvania and New Jersey. We evaluated adults eligible for breast or colorectal cancer screening and visiting with their PCP between September 1, 2014 and August 31, 2016. Primary outcome was clinician ordering of the screening test during the visit. Secondary outcome was patient completion of the tests within 1 year of the visit. To evaluate the outcomes by clinic appointment time, we grouped appointment times by the hour. In the adjusted analysis of patient-visit level data, we used PROC LOGISTIC in SAS to fit a conditional logistic regression, where the conditioning was on the PCP. The models were adjusted for patient demographics, insurance, Charlson comorbidity index, clinic visit type, fixed effects by practice site, year and calendar month, and a covariate for each appointment hour.

RESULTS: Among the 19,254 patients eligible for breast cancer screening, the mean age was 60.2 years, 60.7% were white, and 28.5% were black. Screening test order rates were highest at 8am at 63.7%, declined throughout the morning to 48.7% at 11am, increased to 56.2% at 12pm, and then

declined to 47.8% at 5pm (Adjusted Odds Ratio [aOR] for linear trend: 0.94, 95% CI: 0.93-0.96, $P < .0001$). Trends in screening test completion rates were similar beginning at 33.2% at 8am and declining to 17.8% at 5pm (aOR: 0.95, 95% CI: 0.94-0.97, $P < .0001$). Among the 33,468 patients eligible for colorectal cancer screening, the mean age was 59.6 years, 55.8% were female, 66.2% were white, and 21.8% were black. Screening test order rates were 36.5% at 8am, declined to 31.3% by 11am, increased at 12pm to 34.4%, and then declined to 23.4% at 5pm (aOR: 0.94, 95% CI: 0.93-0.95, $P < .0001$). Trends in screening test completion rates were similar beginning at 28.0% at 8am and declining to 17.8% at 5pm (aOR: 0.97, 95% CI: 0.96-0.98, $P < .0001$).

CONCLUSIONS: Clinician ordering of cancer screening tests significantly declined as the clinic day progressed. Patient completion of cancer screening tests within 1 year of the visit was also significantly lower as the primary care appointment time was later in the day. Future interventions targeting improvements in cancer screening should consider how time of day influences these behaviors.

ASSOCIATION OF RESIDENT PERFORMANCE METRIC FEEDBACK FOR DIABETIC CARE IN PRIMARY CARE CLINICS AND ACHIEVEMENT OF PERFORMANCE METRICS

Timothy J. Brown¹; Salahuddin Kazi¹; Tyler Miller²; Hyemi Chong².
¹UTSW, Dallas, TX; ²VA North Texas Healthcare System, Dallas, TX.
 (Control ID #3185806)

BACKGROUND: Performance feedback during residency is a critical aspect of training. In the primary care clinics, feedback on chronic disease management is important but may not be readily available. Our residency program is divided into 5 "firms" sharing a clinic week in a "4+1" format in which the residents do 4 weeks of inpatient rotations followed by 1 week of clinic. Approximately half of the program has primary care clinic at the VA. The VA has developed guideline-based targets to improve the care of diabetic patients consisting of an annual hemoglobin A1c, achieving A1c<9%, targeting blood pressure to <140/90 mmHg, targeting LDL <100 mg/dL or prescription of a moderate-intensity statin, annual retinopathy referral, and annual nephropathy screening. However feedback related to progress towards these metrics is not readily available to the residents. We sought to improve rates of achievement of these metrics by providing residents with their performance data.

METHODS: Data were obtained prospectively from a continuously-updated EMR-based database. A natural experiment was designed to determine the effect of feedback on achievement of performance metrics. One of the five firms was blinded to this project (no feedback) and the other four firms received weekly email feedback with their performance metrics and an average composite score. All residents in the feedback group were provided data, however only senior residents PGY2 and higher were included in the analysis to account for patient "rollover" from the previous graduating class. After four completed clinic weeks spanning 20 weeks in the academic calendar, data were analyzed. Comparisons were made using two-tailed paired t-tests with alpha of 0.05 to determine if feedback of performance metrics improved achievement of the performance metrics.

RESULTS: Forty-one senior residents were included in the feedback group and ten senior residents were in the no feedback group. Feedback was associated with a mean decrease in composite score for diabetes care of 3.3% [95% confidence interval (CI) 1.38-5.26% decrease, $p=0.009$] compared to no feedback. Similarly, feedback was associated with a 3.75% increase in the number of diabetic patients with hemoglobin A1c >9 [95% CI 2.26-5.23% increase, $p=0.002$] and with an 8.2% decrease in diabetic patients with LDL<100 mg/dL or on moderate intensity statin [95% CI 4.7-11.8% decrease, $p=0.03$] compared to no feedback. No difference was noted in rates of annual hemoglobin A1c screening, retinopathy screening, nephropathy screening, or achievement of blood pressure <140/90 mmHg.

CONCLUSIONS: In this analysis, providing residents with feedback on their diabetic patients did not improve whole-panel achievement of

institutional performance metrics. These results could be affected by potential crossover of patients within the primary care clinic, relatively short follow-up and unknown uptake of feedback by the residents. Further attempts at improvement are ongoing.

ASSOCIATION OF SOCIAL VULNERABILITY WITH TREATMENT BURDEN AND MEDICATION ADHERENCE AMONG PATIENTS WITH HYPERTENSION

Hani A. Abi¹; David Eton²; Mark Linzer³; Elizabeth A. Rogers¹. ¹University of Minnesota, Minneapolis, MN; ²Mayo Clinic, Rochester, MN; ³Hennepin County Medical Center, Minneapolis, MN. (Control ID #3186055)

BACKGROUND: Hypertension is a condition that more than 100 million Americans—nearly 1/4 of adults—suffer from. New hypertension guidelines in the United States increase the number of patients who require treatment and the number of medications taken. This contributes to treatment burden, or the work of self-management and its impact on function and well-being, which may lead to decreased medication adherence. This study examined the associations between treatment burden, medication adherence, and social vulnerability measures among patients with hypertension.

METHODS: We conducted a cross sectional survey of patients within two Minnesota medical systems who had at least two chronic medical conditions. The mailed survey battery consisted of the Patient Experience with Treatment and Self-management measure (PETS), an 11-domain measure of patient-reported treatment burden; four validated measures of social vulnerability (disease management self-efficacy, healthcare provider relational quality, health literacy, and healthcare financial difficulties); and a single-item measure of medication adherence. For those respondents with hypertension, we calculated the correlation between PETS domains, social vulnerability measures, and medication adherence using Spearman's Rho.

RESULTS: The study population ($n=254$) was on average 67 years old, 54% female, 27% non-white, 67% having some college education, and 26% employed. Sixty-six percent reported taking 5 or more prescription medications and 13% reported low medication adherence. We found that higher treatment burden was correlated with lower patient perceived self-efficacy, healthcare provider relational quality, and health literacy, and with higher financial difficulty ($p<0.05$ on all 11 PETS domains). Higher treatment burden was also correlated with lower medication adherence ($p<0.05$ on 6 of 11 PETS domains). Lower medication adherence was correlated with lower healthcare provider relational quality, patient perceived self-efficacy, and health literacy; and with higher financial difficulty.

CONCLUSIONS: Patient-reported treatment burden is associated with lower medication adherence and greater social vulnerability among patients with hypertension. Lower medication adherence is associated with greater social vulnerability. Adding medications to follow the new hypertension guidelines may increase treatment burden, decrease medication adherence, and disproportionately affect socially vulnerable populations. Clinicians and future researchers should consider this in efforts to curb disparities in hypertension outcomes.

ASSOCIATION OF STATE LAWS MANDATING PRESCRIPTION DRUG MONITORING PROGRAM USE BY PRESCRIBERS ON DISCONTINUATION OF CHRONIC OPIOID THERAPY IN VETERANS

Jonathan Arnold⁴; Xinhua Zhao¹; Florentina Sileanu²; Maria K. Mor²; John P. Cashy²; Patience Moyo³; Carolyn T. Thorpe²; Chester Good²; Thomas R. Radomski⁴; Michael J. Fine²; Walid F. Gellad². ¹VA Pittsburgh HealthCare System, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³Brown University School of Public Health, Providence, RI; ⁴University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #3168221)

BACKGROUND: Several states have mandated that prescribers check prescription drug monitoring programs (PDMPs) prior to opioid

prescribing and periodically during therapy. Despite concerns about inappropriately abrupt opioid discontinuation resulting from this policy, no studies have evaluated the extent to which this occurs. Our objective was to evaluate the impact of PDMP mandates on discontinuation of chronic opioid prescribing for Veterans managed in the Veterans Affairs Administration (VA) Healthcare System.

METHODS: We conducted an interrupted time-series (ITS) study of opioid discontinuation in Veterans without cancer diagnoses in 4 states that implemented a PDMP use mandate from 2010-2014: Ohio (OH; Nov 2011), West Virginia (WV; Jun 2013), Kentucky (KY; Jul 2012), and Tennessee (TN; Apr 2013). We used Veterans in neighboring states without a mandate as controls. We built monthly cohorts of Veterans with 305 days of a VA-prescribed opioid in the prior 365 days. We defined discontinuation as a 90-day period without a VA prescribed opioid. For each state with a PMDP mandate and its pooled control we estimated monthly discontinuation rates adjusted for patient-level demographic and clinical covariates. We calculated the difference between the mandate states and their controls; and we used these differences in our ITS models with offset and slope-change terms at the time of the mandate. We included 12-months prior to and following the mandate in each state. All reported percentages represent absolute percentage points.

RESULTS: We built monthly cohorts for 4 PMDP mandate and 12 neighboring control states (3-7 controls for each mandated state). Monthly cohort sizes ranged from 4,733-8,909 Veterans in the mandate states and 11,985-41,163 in the controls, a total of 2.5M veteran-months. The average adjusted discontinuation rates in the 12 months prior to (after) the mandates were 0.7 (0.9)% in OH, 0.7 (0.7)% in WV, 0.8 (1.3)% in KY, and 0.8 (0.9)% in TN. There was no difference in the pre-mandate discontinuation rate between mandate states and controls. TN was the only state with an increasing baseline trend in discontinuation compared to its control of 0.02%/month ($p=0.03$). KY's mandate was associated with an immediate 1.03% ($p<0.001$) increase in discontinuation rate. Mandates in KY and TN were associated with a decreasing trend in discontinuation of -0.09% ($p=0.001$) and -0.05% ($p<0.001$) per month respectively. There was no change associated with the mandates in OH or WV.

CONCLUSIONS: For VA managed Veterans, state laws mandating prescriber PDMP use had little absolute effect on discontinuation of chronic opioid prescribing. We did observe a clinically significant but short lived increase in opioid discontinuation in KY immediately following its mandate, however the overall discontinuation rate remained low. These results suggest that PDMP use mandates did not cause abrupt discontinuation of long-term opioid therapy within VA.

ASSOCIATION OF THE IMPLEMENTATION OF THE PATIENT-CENTERED MEDICAL HOME WITH QUALITY OF LIFE IN PATIENTS WITH MULTIMORBIDITY

Linnaea C. Schuttner^{1, 3}; Ashok Reddy^{1, 3}; Ann-Marie Rosland^{2, 4}; Karin M. Nelson^{1, 3}; Edwin Wong^{1, 3}. ¹VA Puget Sound Healthcare System, Seattle, WA; ²VA Pittsburgh, Pittsburgh, PA; ³University of Washington, Seattle, WA; ⁴University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #3165054)

BACKGROUND: The patient-centered medical home (PCMH) has clinical benefits for patient with multimorbidity, yet the association with patient-reported outcomes such as health-related quality of life (HRQoL) is unknown. Therefore, we examined the association of the Veterans Affairs (VA) implementation of the PCMH model, the Patient Aligned Care Team (PACT), and HRQoL in multimorbid adults.

METHODS: We performed a retrospective cohort study of

m multimorbid patients (2 or more chronic diseases in 2 or more body systems, n = 22,095) who responded to a patient experiences survey in 2013-2014 and received VA primary care in 2012. PCMH implementation at a clinic was measured in 2012 with the validated PACT Implementation Progress Index (PI²); Higher PI² scores indicate better performance on 8 domains (access; care continuity; care coordination; comprehensiveness; self-management support; communication; shared decision-making; and team-based care). HRQoL was measured from the patient survey with Short Form-12 physical and mental component scores (PCS, MCS). Surveys were weighted to the VA population. Generalized estimating equations, adjusted for patient and clinic characteristics, were used to model HRQoL against 1) quintiles of PI² as the primary exposure, 2) highest and lowest versus mid-quartiles of PI² in exploratory analyses of the 8 PI² domains, and 3) an interaction analysis of patients with and without hospitalizations in 2012.

RESULTS: The cohort was mostly male (96%) and on average 68 years old with 4.4 chronic diagnoses. Compared to patients seen at the lowest-scoring PI² clinics, receiving care in the highest PI² clinics was associated with a 3.0 point higher adjusted marginal mean PCS [42.7 vs. 39.7, $P<0.001$], but a 1.2 point lower MCS [36.3 vs. 35.1, $P=0.04$]. Patients with prior hospitalizations seen in clinics with higher compared to lower PI² scores had a 2.6 point greater MCS ($P=0.02$); Those without prior hospitalizations seen in higher compared to lower PI² clinics had an MCS that was 1.6 points lower ($P<0.01$). Better performance on the communication and shared decision-making domains was significantly associated with a higher mean PCS (1.0 points higher for average versus lowest PI² for communication, $P=0.018$; 0.9 points higher for average versus lowest PI² for shared decision-making, $P<0.01$).

CONCLUSIONS: Multimorbid patients seen in clinics with greater PCMH implementation reported a clinically significant higher physical HRQoL, which may be due to better patient-provider communication and shared decision-making. Care from higher performing clinics was associated with a small but not clinically significant lower score for mental HRQoL, which may be related to disease severity as measured by hospitalizations. Our findings add HRQoL to the known benefits of the PCMH model.

ASSOCIATION OF USE OF THE NEJM KNOWLEDGE+ PRODUCT AND PERFORMANCE ON THE ABIM IM-MOC EXAM

Michael Healy^{1, 2}; Roy Phitayakorn^{1, 2}; Carl Gustaf Stefan Axelsson¹; Matthew O'Rourke²; Lauren M. Duhigg³; Bradley Gray³. ¹Massachusetts General Hospital, Harvard Medical School, Boston, MA; ²NEJM Group, Waltham, MA; ³American Board of Internal Medicine, Philadelphia, PA. (Control ID #3165130)

BACKGROUND: Internal medicine physicians who are completing their American Board of Internal Medicine Internal Medicine Maintenance of Certification (ABIM IM-MOC) requirements must eventually pass a knowledge assessment (i.e., MOC examination). Although physicians have many options to choose from as they prepare for this assessment, including the NEJM Knowledge+ Internal Medicine Board Review (NEJM Knowledge+) product, there exists no research related to the use of this or other similar study aids and MOC examination performance.

METHODS: To address this gap, we compared ABIM IM-MOC examination performance among similar physicians who did and did not use NEJM Knowledge+. Our physician sample included 177 physicians who attempted an ABIM IM-MOC examination from 2014-2017 and completed at least 75% of the NEJM Knowledge+ product prior to the ABIM IM-MOC examination and 177 matched

case-controls who did not use the NEJM Knowledge+ product. One limitation of our analysis is that physicians may have not used NEJM Knowledge+ exclusively (e.g., they could have also taken an exam review course). Physicians were eligible for the study if they were non-grandfather general internists. Case-control matched characteristic included sex, birth country (U.S. vs. international), medical school country (U.S. vs. international), year of MOC examination, MOC cycle number (1st vs. 2nd), examination attempt number within the MOC cycle (1 vs. 2) and decile ranked score on the first attempt at the initial IM certification examination. Performance on the ABIM IM-MOC examination, which was the primary outcome of interest, was operationalized as indicators for 1) passing the ABIM IM-MOC examination, 2) having an examination score in the top quartile of the ABIM IM-MOC examination and 3) being in the bottom quartile on the ABIM IM-MOC examination, focusing on top and bottom quartile ranks. Quartile cut-offs were calculated across all physicians attempting the examination within a year.

RESULTS: When comparing NEJM Knowledge+ users to non-users on passing the MOC examination, the difference was 9.6% ($p=<0.001$) with a regression adjusted difference of 10.6% ($p=<0.001$). When comparing NEJM Knowledge+ users to non-users on having an examination score in the top quartile on the MOC examination, the difference was 9.6% ($p=0.016$) with a regression adjusted difference of 10.7% ($p=0.009$). Further, when comparing NEJM Knowledge+ users to non-users on being in the bottom quartile on the MOC examination, the difference was -9.6% ($p=0.003$) with a regression adjusted difference of -10.8% ($p=<0.001$).

CONCLUSIONS: Physicians who were users of NEJM Knowledge+ had better performance on ABIM's IM-MOC examinations than similar physicians who were not users.

ASSOCIATIONS BETWEEN AGE DISPARITIES IN TYPE 2 DIABETES AND RATES OF DIABETES-RELATED HOSPITAL USE AND DIABETIC COMPLICATIONS

David C. Lee^{1, 1}; Ta'Loria Young²; Christian A. Koziatek¹; Christopher J. Shim³; Marcella Osorio¹; Andrew J. Vinson¹; Joseph Ravenell¹; Stephen P. Wall¹. ¹New York University School of Medicine, New York, NY; ²Touro College of Osteopathic Medicine, New York, NY; ³California Northstate University College of Medicine, Elk Grove, CA. (Control ID #3138339)

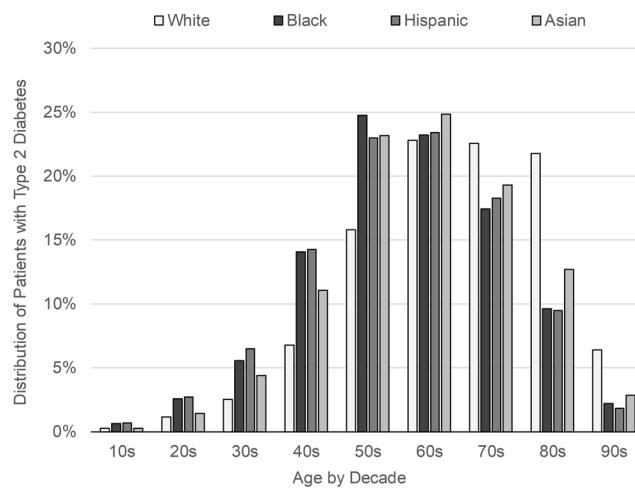

BACKGROUND: Current guidelines for diabetes screening start at age 45, but disparities in certain subgroups exist and poor diabetic outcomes are known to cluster in specific neighborhoods. The objective of this study was to quantify disparities in the age distribution of patients with type 2 diabetes by sex, race/ethnicity, and geographic location. We also studied how patient age relates to diabetes-related hospital use and development of diabetic complications.

METHODS: Using all-payer hospital claims data, we performed a cross-sectional analysis of patients with type 2 diabetes. Our study included patients in New York City as identified by geocoded home address. Patients aged 10 to 100 years old were identified as having type 2 diabetes based on diagnosis codes from emergency claims data from 2011-2015. Our main measures included the estimated prevalence of type 2 diabetes at each year of life, the age distribution of patients as stratified by decade, and the comparison of patient age in geographic hotspots of frequent diabetes-related hospital use and diabetic complications.

RESULTS: We identified 576,306 unique patients diagnosed with type 2 diabetes, which represented over half of all cases in New York City. Minority subgroups were on average 5.5 to 8.4 years younger than non-Hispanic White patients. Males with type 2 diabetes were 2.6 years younger than females. At 45 years of age, the estimated prevalence of type 2 diabetes was 10.9% among Black patients compared to 5.2% among White patients. In

our geospatial analyses, patients with type 2 diabetes were on average 5.9 years younger in hotspots of diabetes-related emergency department use and inpatient hospitalizations. The average age of patients with type 2 diabetes was 1.5 to 2.2 years younger in hotspots of microvascular diabetic complications.

CONCLUSIONS: We identified profound disparities in the age of patients with type 2 diabetes among minorities and in neighborhoods with poor health outcomes. The younger age of these patients may be due to earlier onset of diabetes and/or earlier death from diabetes-related complications. Our findings demonstrate the need for geographically targeted interventions that promote earlier diagnosis and better glycemic control to reduce disparities in diabetes burden.

Age Distribution of Patients with Type 2 Diabetes by Race and Ethnicity

ASSOCIATIONS BETWEEN NEIGHBORHOOD AND POLICE VIOLENCE, HYPERVIGILANCE, AND HYPERTENSION AMONG RACIAL/ETHNIC MINORITIES IN CHICAGO

Nichole Smith¹; Dexter Voisin¹; Joyce P. Yang²; Elizabeth L. Tung¹. ¹University of Chicago, Chicago, IL; ²Stanford University School of Medicine, Palo Alto, CA. (Control ID #3183498)

BACKGROUND: Hypervigilance, a state of heightened awareness and watchfulness, is a consequence of violence that has been linked to negative psychosocial outcomes. While hypervigilance has been well-documented in Veteran populations, it has been poorly quantified in community populations that may experience chronic exposure to violence. Moreover, the long-term health effects of hypervigilance are not well understood. The objective of this study was to examine community and police violence, their association with hypervigilance, and the health consequences of hypervigilance in a sample of predominantly racial/ethnic minority adults.

METHODS: Primary care patients (N=506) were recruited from clinics in 2 epicenters of violent crime and surveyed using computer-assisted personal interviewing software. Lifetime violence exposure was measured using the Brief Trauma Questionnaire (BTQ), which included items for being a direct victim of community violence, or a witness, friend or relative of someone who died violently. BTQ items were also adapted to query participants about exposure to police violence. Hypervigilance was measured using the Brief Hypervigilance Scale. Linear regression models were used to assess

hypervigilance scores as a function of violence exposure type, controlling for age, gender, race/ethnicity, educational attainment, insurance status, and employment status. Survey results were then paired with the electronic health record to examine associations between hypervigilance scores and blood pressure.

RESULTS: The sample included patients from an academic medical center (n=419) and a federally-qualified health center (n=87) in Chicago. Mean age was 60 years (SD=13). The majority identified as Black/African-American (75%) or Hispanic/Latino (14%). More than half (56%) were insured by Medicaid/Medicare. Two-thirds (62%) reported prior experience with community violence, and one-third (30%) reported prior experience with police violence. Of the 263 participants who reported a previous police stop, 19% met criteria for the stop being a traumatic event. The mean hypervigilance score in our population was 54.7% (SD=28.1), 5.7% higher than the score correlated with PTSD in the validation sample. While experience with community violence was marginally associated with a 5.5% higher hypervigilance score (95% CI, 0.2-10.8), experience with police violence was associated with a 9.8% higher hypervigilance score (95% CI, 4.1-15.5). Among participants who reported a police stop, classification as a traumatic event was associated with an 18.6% higher hypervigilance score (95% CI, 10.3-26.9). A hypervigilance score in the highest quartile was associated with higher systolic blood pressure (10.3 mmHg; 95% CI, 4.3-16.2).

CONCLUSIONS: Neighborhood and police violence may have important linkages to both psychological and physical health. Understanding these linkages may help to inform both neighborhood policing practices and healthcare responses to violence in at-risk communities.

ASSOCIATIONS BETWEEN REASONS FOR HOSPITALIZATION IN THE ELDERLY AND ONE-YEAR MORTALITY

Chana A. Sacks; Katrina Armstrong; Thomas McCoy. Massachusetts General Hospital, Boston, MA. (Control ID #3185288)

BACKGROUND: Optimal clinical decision making among the elderly is challenged by uncertain and potentially inaccurate understanding of life expectancy. Because clinicians can conflate reversibility of the condition prompting a hospitalization with longer-term likelihood of survival, determining 1-year mortality following common reasons for hospitalizations could improve clinicians' understanding of patient prognosis and clinical decision making, as well as the accuracy of information provided to patients and their families.

METHODS: We conducted a retrospective cohort study, analyzing data from individuals discharged from Medicine services at 2 academic medical centers between January 1, 2005 and December 31, 2016. We included all patients 70 years of age or older who were admitted for 10 common diagnoses and survived to hospital discharge. We divided age into categories: 70-79 years, 80-89 years, and 90 and older. The primary outcome was death within 1 year after discharge as reported by public records (a composite from the Massachusetts Department of Public Health and Social Security Death Index).

RESULTS: The cohort included 36,291 hospitalizations of 23,071 unique individuals. 51% were male; 83% were white, and mean age was 81 years. The analysis included 116,404 person-years of follow up, with a median follow-up of 876 days. Overall, 26.3% of the cohort had died within 1 year of discharge. The table describes the variation in 1-year mortality based on age and reason for admission.

CONCLUSIONS: There was substantial variation in 1-year mortality based on age and reason for admission. For example, people in their 70s admitted for a urinary tract infection had a higher 1-year mortality than those in their 90s admitted with syncope. Accurate prognostication is important to inform clinicians, patients, and their

families as they plan for the future and navigate decisions about goals of care.

| Reason for Admission | Percent of patients who died within 1 year after discharge | | | |
|-----------------------------|---|-------|-------|-----|
| | Age | 70-79 | 80-89 | 90+ |
| Syncope | 6% | 10% | 22% | |
| Nonspecific chest pain | 6% | 10% | 19% | |
| Acute MI | 11% | 20% | 33% | |
| COPD | 19% | 27% | 30% | |
| GI hemorrhage | 20% | 24% | 39% | |
| Pneumonia | 25% | 27% | 34% | |
| UTI | 26% | 30% | 41% | |

The percent of patients in each age group, for each reason for admission who died within 1 year after discharge.

ASSOCIATIONS BETWEEN SOCIAL RISK FACTORS AND DIALYSIS FACILITY PERFORMANCE IN THE END-STAGE RENAL DISEASE QUALITY INCENTIVE PROGRAM

Andrew C. Qi; Anne M. Butler; Karen E. Joynt Maddox. Washington University School of Medicine, Saint Louis, MO. (Control ID #3139408)

BACKGROUND: Medicare's End-Stage Renal Disease Quality Incentive Program (ESRD QIP) is a mandatory pay-for-performance program for U.S. dialysis facilities. While analyses of similar value-based payment programs in other settings have shown performance to be related to social risk factors such as poverty and access to care, it is unknown whether the ESRD QIP displays similar patterns. We aim to determine whether dialysis facility performance and associated financial penalties under the ESRD QIP are associated with facility-level social risk factors.

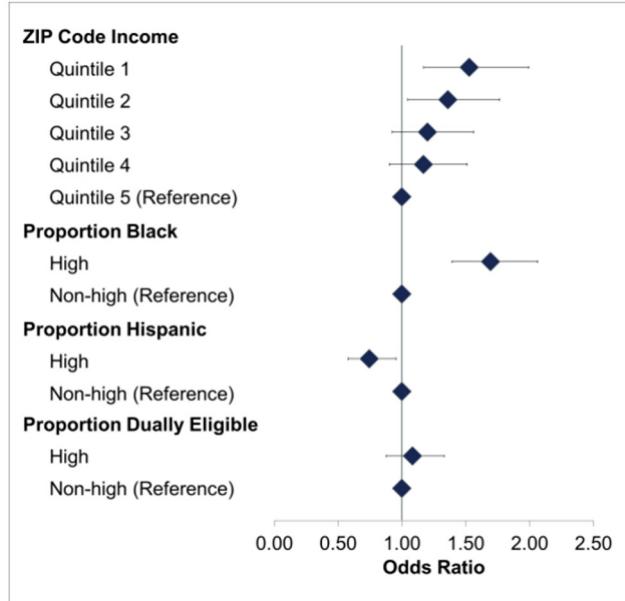

METHODS: Retrospective, cross-sectional analysis of 6,314 U.S. dialysis facilities using data from the United States Renal Data System, American Community Survey, and Medicare for the 2018 ESRD QIP payment year. We used linear and logistic regression models to determine whether social risk factors, including poverty, race/ethnicity, and neighborhood income were related to performance and risk of receiving a penalty.

RESULTS: Facilities located in low-income ZIP codes and with high proportions of black patients had worse performance under the ESRD QIP and higher rates of penalization. In a multivariate model accounting for key facility-level characteristics, significant effects

persisted for facilities in the bottom quintile of ZIP code income (odds ratio [OR]=1.53, p=0.002, vs. top quintile) and those in the top quintile of proportion of black patients served (OR=1.69, p<0.001, vs. other facilities). Among other covariates examined, independent (versus chain) status, large facility size, and urban location were the strongest structural predictors of poor performance and penalties.

CONCLUSIONS: Dialysis facility performance and financial penalization may be influenced by social risk factors potentially independent of the quality of care provided. Future research is needed to elucidate the interactions between sociodemographic factors and outcomes under the ESRD QIP and to determine appropriate adjustments to pay-for-performance program design to account for social risk.

Adjusted Odds of Receiving Penalties by Facility Risk Factor

ASSOCIATIONS OF HEALTH LITERACY, PATIENT ACTIVATION, AND PATIENT-PROVIDER COMMUNICATION REGARDING HIGHER-RISK MEDICATION USE

Marina Arvanitis¹; Laurie A. Hedlund¹; Laura M. Curtis¹; Stephanie Batio¹; Stacy Bailey¹; Danielle M. McCarthy¹; Michael K. Paasche-Orlow²; William G. Adams²; Mary J. Kwasny¹; Amy Moore¹; Michael S. Wolf¹. ¹Northwestern University, Chicago, IL; ²Boston University, Boston, MA. (Control ID #3185951)

BACKGROUND: Health literacy and patient activation have been independently associated with a variety of health outcomes and behaviors. Despite these independent associations, both are thought to affect health, at least in part, by way of communication between patients and healthcare providers. We sought to better understand the similarities and differences in associations between health literacy, patient activation, and patient-provider communication in the context of prescribed medication.

METHODS: Baseline data was analyzed from an NIDDK-funded, 2-arm, patient-randomized controlled trial of a medication risk communication and surveillance strategy. Participants were adults cared for at one of 7 federally qualified health centers, who received a new prescription or dose of a medication considered to be of higher risk per FDA labeling. All participants completed the Consumer Health Activation Index (CHAI), the Newest Vital Sign (NVS), and modified versions of the supplemental items of the Consumer Assessment of Health Providers Survey (CAHPS) to evaluate patient-perception of the extent and quality of verbal counseling on medications.

RESULTS: In all, 581 participants completed both the health literacy (NVS) and patient activation (CHAI) assessments at baseline. Participants' mean age was 50, 71% were African-American, and 40% reported an income of less than \$10,000/year. The majority had low to moderate patient activation and limited health literacy (84% and 68% respectively). There was no correlation between CHAI and NVS total scores ($\rho = -0.05$, $p = 0.20$) overall. However, the majority (67%) of those with limited health literacy also reported CHAI scores consistent with low to moderate activation ($p = 0.05$). Compared to those with high activation, participants with low to moderate activation were less likely to report having received instructions from their provider about how to take their newly prescribed medication (330 vs 72, $p = 0.04$), or had possible side effects explained (192 vs 46, $p = 0.05$). We did not observe similar differences among participants across health literacy levels. By contrast, those with limited health literacy were more likely than those with adequate health literacy to report their provider had suggested ways to help them remember to take their medication (146 vs 41, $p = 0.0007$). Neither patient activation nor health literacy was associated with patient-provider communication regarding risks, benefits, and patient opinions regarding medication use.

CONCLUSIONS: Patient activation and health literacy were associated with different patient-reported patterns of provider communication regarding high-risk medication use, and neither were associated with higher-level discussions about risks, benefits, or patient preferences. Ongoing, longitudinal analyses will help determine the directionality of these associations, and help to better target communication interventions to providers, or patients depending on their level of activation and/or health literacy.

ATRIAL FIBRILLATION IS ASSOCIATED WITH INCREASED IN-HOSPITAL MORTALITY IN PATIENTS WITH CLOSTRIDIUM DIFFICILE INFECTION.

Dipesh Ludhwani¹; Maryna Shayuk¹; Karam Khaddour¹; Belaal Sheikh². ¹Rosalind Franklin University of Medicine and Science at Northwesern-McHenry hospital, McHenry, IL; ²Chicago Medical School, McHenry, IL. (Control ID #3176126)

BACKGROUND: Clostridium Difficile Infection (CDI) and Atrial Fibrillation (AF) are common medical entities encountered in the hospital. Both conditions warrant hospital admission and have been well established as major health care burdens of the society. Previous studies have identified advanced age as a poor prognostic factor for CDI. Large-scale studies analyzing outcomes of CDI in presence of concomitant AF are lacking.

METHODS: All patients with age greater than 18 years and admitted under the primary diagnosis of CDI (ICD-10-CM code A04.72) ($n=66,602$) were identified in 2016 National Inpatient Sample (NIS). ICD-10 codes I48.0, I48.1, I48.2, I48.3, and I48.4 were used to further categorize patients into two groups based on the presence or absence of AF. Patients with CDI and without previous history of AF served as the reference population. Using multivariate logistic regression model, confounders were adjusted and in-hospital mortality was compared for both groups. Additionally, the odds ratios were calculated for other complications such as acute renal failure (N17), hypovolemic shock (R57.1) requiring vasopressor support (3E033XZ), and acute systolic or diastolic heart failure exacerbation (I50.21, I50.23, I50.31, and I50.33). Multivariate linear regression analysis was done to compare the total length and cost of hospital stay for both groups.

RESULTS: Amongst 66,602 admissions for CDI, 8668 patients were found to have a secondary diagnosis of AF. Patients with CDI and AF had a 29% increase odds of in-hospital mortality as compared to the reference population (OR=1.29, 95% CI=1.19-1.41, $p<0.0001$). These patients were also noted to have a higher probability of acute renal failure, acute heart failure exacerbation and hypovolemic shock requiring vasopressor support (see table 1). Mean length and cost of the hospital stay were higher for patients with CDI and AF.

CONCLUSIONS: History of AF in patients admitted with CDI is associated with longer complicated hospital course and increased in-hospital mortality. Resuscitation for hypovolemia and acute renal failure tends to occur at the expense of worsening heart failure. Treatment strategy for such patients should include a multidisciplinary team approach and intensive monitoring with a close eye on hemodynamic status.

ATTITUDES TOWARDS GENETICS TRAINING AMONG INTERNAL MEDICINE HOUSE STAFF

Raja Chandra Chakinala²; Steven Murphy¹; Akshay Khatri²; Leanne Forman²; Jagjit Kholas²; Kartik Dhaduk²; Melissa Gennarelli²; Rebecca Newman²; Christopher Nabors². ¹New York Medical College, Valhalla, NY; ²New York Medical College at Westchester Medical Center, Valhalla, NY. (Control ID #3163528)

BACKGROUND: The availability of genetic testing information is increasing. Perceptions regarding its utility vary among practicing providers. In this study, we sought to determine the attitudes and practices of residents in training towards genetic testing.

METHODS: Categorical trainees at a tertiary care center completed a baseline survey (12-2017 to 4-2018) followed by an educational intervention based on materials from the Genetics Education Canada Knowledge Organization (4 hours of lecture; 3-hours online training) and then a post-training survey (5-2018).

RESULTS: Baseline response rate was 80% (36/45): PGY-1 (16, 44%), PGY-2 (10, 28%), PGY-3 (10, 28%). 72% (26) had taken a medical school genetics course; most reported prior training to be insufficient (21, 61%). 28% (10) ordered a genetic test once/month or once/year 22% (8). Common tests were for thrombophilia (52%), BRCA (20%) and hemochromatosis (8%). Respondents believed patients would be interested in genetic testing (61%, 22), that testing is useful (61%, 22) and within 5 years would improve outcomes (50%, 18), but could lead to insurance discrimination (36%, 13). 61% (22) knew BRCA transmission mode, frequencies of BRCA mutations among breast cancer patients (67%, 24) and the percentage of persons with Lynch Syndrome who would develop colorectal cancer (72%, 26). A post-training pilot survey was offered to those who attended all lectures (N=15). Of those, 11 responded. Post-intervention results differed in a number of respects. Perceived frequency of testing increased to 36% monthly and to 45% yearly. 72% and 18% reported they were somewhat or much more able to manage genetic testing after training. Pre-training/post-training mean self-confidence ratings (low 1 to high 5) in the ability to elicit information were (3.46/3.64, p=0.08), to interpret results (2.77/3.45, p=0.29), to evaluate usefulness (2.69/3.27, p=0.04), to order test/referral (2.49/3.45, p=0.07), to discuss risks/benefits (2.37/3.45, p=0.02) and to provide counselling (2.46/3.36, p=0.10). Following training, 73% believed their training was either sufficient/more than sufficient compared to 60% prior to training. Medical knowledge related to hereditary cancers was comparable pre/post-intervention, while all residents agreed (post-intervention) on the importance of taking a detailed family history to interpret tests related to late onset Alzheimer's disease.

CONCLUSIONS: In this study, internal medicine residents were receptive to learning more about genetic testing and believed results of genetic tests would become more important as a guide to treatment in the next five years. Following a core set of lectures and online training, most respondents felt more confident in managing genetic test information and reported ordering genetic tests more frequently. Medical knowledge related to hereditary cancers was similar following training. Due to the small post-intervention pilot sample size, results will require further study for confirmation.

AVAILABILITY OF GROCERY DELIVERY IN AREAS WITH LIMITED FOOD ACCESS: AN EIGHT-STATE ANALYSIS

Eric Brandt³; David Silvestri³; Jerold Mande¹; Joseph S. Ross². ¹Tufts University, Boston, MA; ²Yale University School of Medicine, Woodbridge,

CT; ³Yale University School of Medicine, New Haven, CT. (Control ID #3184225)

BACKGROUND: The United States Department of Agriculture (USDA) Supplemental Nutrition Assistance Program (SNAP) provides federally-funded nutritional economic support to qualifying low-income individuals and families to help reduce financial barriers to food access. Nevertheless, about one fourth of the 15 million households receiving SNAP nationwide currently reside in USDA-defined "foods deserts"—census tracts with below-median incomes, low grocer availability, and limited vehicular access. To expand food access, the 2014 Farm Bill authorized an Online Purchase Pilot (OPP) enabling SNAP recipients to spend benefits on groceries online. However, benefits cannot be used to pay for grocery delivery fees, potentially limiting the impact of online purchasing for increasing access to grocers, particularly in areas with limited vehicular access. Accordingly, we sought to quantify the proportion of USDA-defined food deserts and SNAP households in OPP states serviceable by existing grocery delivery networks via online grocers.

METHODS: We used the USDA Economic Research Service Food Access Research Atlas database to identify food deserts in OPP states (AL, IA, MD, NE, NJ, NY, OR, WA). The US Housing and Urban Development United States Postal Service ZIP code crosswalk data allowed census tract to zip code conversion. Using the USDA Food and Nutrition Service SNAP retailer database, we identified all retailers with >5 stores in study states and determined if they delivered to a ZIP code using manual retailer website review. Food desert census tracts were classified as fully-, partially-, or not-deliverable, according to whether all, some, or no corresponding ZIP codes fell within delivery areas, respectively. Primary outcomes were the proportion of food deserts and SNAP households serviceable by grocery delivery, stratified by urban status.

RESULTS: Food deserts comprise 9.5% (n=1,250) of census tracts and 18.4% (n=506,863) of SNAP households in OPP states. Grocery delivery is available fully to 85.9% (n=1,074), partially to 2.6% (n=32), and not at all to 11.5% (n=144) of food desert census tracts, and to 87.3% (n=442,643), 2.7% (n=13,696), and 10.0% (n=50,524) of SNAP households within food deserts, respectively. Among rural food desert tracts (n=59) grocery delivery is available fully to 0, partially to 27.1% (n=16), and not at all to 72.9% (n=43), while in urban food deserts (n=1,191), grocery delivery is available fully to 90.2% (n=1,074), partially to 1.3% (n=16), and not at all to just 8.5% (n=101) (p<0.001).

CONCLUSIONS: Expanding SNAP benefits for grocery delivery in OPP states could increase access to grocery stores for roughly 7 of 8 food desert census tracts and corresponding SNAP households, with greatest impact in urban areas. Planned OPP expansion nationwide could consider financing grocery delivery, which if coupled with incentives that direct consumers to highest-quality food choices could increase the utility of online grocery purchasing.

BARRIERS AND FACILITATORS OF SELF-MANAGEMENT BEHAVIORS AMONG PATIENTS WITH MULTIPLE CHRONIC CONDITIONS: A MIXED-METHODS INVESTIGATION

Rachel O'Conor¹; Kimberly A. Muellers²; Andrea Russell¹; Sarah Wright¹; Sara Thompson²; James W. Griffith¹; Michael S. Wolf¹; Juan Wisnivesky³; Alex Federman². ¹Northwestern University, Chicago, IL; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³Mount Sinai School of Medicine, New York, NY. (Control ID #3177569)

BACKGROUND: Multimorbidity challenges disease management among older adults, yet self-management programs are often condition-specific. We investigated how individuals managing multiple chronic conditions (MCC) navigate their conditions and identify any difficulties they face in their management.

METHODS: We conducted a mixed-methods study using semi-structured interviews among a subset of patients (n=18) participating in a cohort study

(n=302) of adults with COPD, hypertension, and diabetes. Participants self-reported their nutrition using the Hypertension Self-Care Activity Level scale, and medication adherence for each of the three conditions using the Medication Adherence Report Scale, and were categorized as good (adequate adherence to all medications), mixed (adequate and poor adherence across medications), or poor (poor adherence to all medications). Qualitative interviews explored patients' experiences with MCC and their self-care strategies. Four investigators used content and constant comparative analysis to analyze transcripts and compared quantitative and qualitative data.

RESULTS: Among the subsample, the mean age was 65 years, 49% were male, 50% black, and 8, 7, and 3 individuals demonstrated good, mixed, and poor adherence. Individuals reported an overall health management strategy (taking medications, engaging in physical activity, avoiding food high in fat, salt, or sugar, and eliminating tobacco), as opposed to managing each condition separately. Individuals with good or mixed adherence described a daily medication routine that facilitated regular medication taking behaviors. Walking was universally recognized as beneficial, but few engaged in it regularly, due to co-morbidities or inclement weather. Those who did had access to fitness centers with senior programming. Regarding their diet, patients reported avoiding unhealthy foods, rather than seeking nutritious options. While many were aware that they should eat healthy, quantitative data found only 2 patients had high diet quality and qualitative data illustrated many misperceptions regarding what constituted healthy foods (i.e. eliminating candy, yet drinking soda frequently). Individuals with mixed adherence sought to maintain their mental well-being through mental calmness. Many reported coexisting mental illness and managing their behavioral health was critical to their health. Lastly, intrinsic motivation to adopt healthy lifestyle behaviors and adhere to prescribed medications did not vary across adherence groups; however, socioeconomic stressors were common among most participants and challenged their ability to follow through with their entire self-care regimen.

CONCLUSIONS: We found patients with MCC were highly motivated and aware of the lifestyle modifications they needed to make, but behaviorally, many may only require small adjustments in order to support behavior change. A tailored approach to patients' personal barriers (social, behavioral, misperceptions) may improve self-management programs.

BARRIERS AND FACILITATORS TO ENGAGING HIGH-NEED VETERAN PATIENTS: REFLECTIONS OF KEY STAKEHOLDERS IN VA'S PRIMARY CARE INTENSIVE MANAGEMENT (PIM) TEAMS

Alicia Bergman¹; Susan E. Stockdale²; Marian L. Katz³; Donna M. Zulman⁴; Evelyn T. Chang⁵. ¹VA Greater Los Angeles, North Hills, CA; ²Greater Los Angeles VA Healthcare System, Sepulveda, CA; ³Veterans Health Administration, North Hills, CA; ⁴Stanford University and VA Palo Alto, Stanford, CA; ⁵VA- Greater Los Angeles, Los Angeles, CA. (Control ID #3184399)

BACKGROUND: Patient engagement among complex high-need patients in intensive primary care programs can be challenging, as many patients experience medical, social, and behavioral barriers to active participation in their care. The Veterans Health Administration (VA) has implemented and tested intensive primary care programs called PACT Intensive Management (PIM). Our goal was to describe barriers and facilitators to engaging high-risk patients by conducting a qualitative analysis of VA PIM staff members' interviews.

METHODS: Semi-structured interviews with VA PIM staff members and program leaders regarding their experiences with and reflections on PIM. Interviews were recorded, transcribed, and analyzed to identify patient engagement barriers and facilitators. Twenty-nine interdisciplinary staff members who care for complex high-need patients, including physicians, nurses, psychologists, and social workers.

RESULTS: Participants described two main types of barriers and facilitators: those related to patient characteristics and those related to provider/

system level characteristics. Patient-level characteristics that facilitated engagement in PIM and their healthcare included: having a pre-existing motivation to improve one's health, having certain chronic conditions and already adhering to a regimen, being a "frequent flier" (e.g., multiple visits per week), being lonely and welcoming human contact, having a desire for extra assistance and interaction, and having been a prior recipient of home-based primary care services and being habituated to healthcare staff entering homes. Provider/system or other-level characteristic-related engagement facilitators included providers making home visits and assessing a patient's home environment, providers having successfully established relationships with patient, patient's family members, connecting patients with other programs and services (e.g., VA or non-VA), having mental health services offered in the primary care clinic (e.g., assisting patients to avoid stigma). Patient-level characteristics that posed a barrier to engagement included: an active substance use disorder, mental health conditions (e.g., depression, anxiety), and non-adherence to recommended treatment regimens. Provider/system or other-level characteristic-related engagement barriers included the time intensive nature of the PIM work, providers changing (e.g., rotating residents), provider compassion/empathy fatigue and/or not understanding psycho-social issues, and obstruction of care by the patient's caregiver.

CONCLUSIONS: Staff in intensive primary care programs identified numerous patient- and provider/system-level factors that influence the engagement of complex, high-need patients and may serve as targets for focused interventions. Increased awareness of barriers and facilitators to patient engagement among high-risk patients may inform intervention design for intensive primary care programs and other services for high-need patients.

BARRIERS TO WELLNESS: FACTORS CONTRIBUTING TO PROVIDER BURNOUT IN AN URBAN ACADEMIC PRACTICE

Kira Y. Xie; Stephanie Duarte; Gabi Schiller; Lauren Peccoralo. Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3185936)

BACKGROUND: Medical provider burnout is now recognized as an increasingly prominent problem threatening the integrity of the medical profession. Compared to other professions, physicians are 36% more likely to experience symptoms of burnout, with high rates of burnout in primary care providers. Burnout can negatively impact many factors such as productivity, patient trust, and provider mental health. While providers have many possible sources of burnout, the unique milieu of stressors in each clinic environment must be assessed to ensure key contributors are attended to. In our study, we analyzed free text survey responses in order to best identify challenges to provider wellness at an urban academic continuity practice.

METHODS: Based on the American Medical Association's STEPS Forward program, our Division of General Internal Medicine formed a faculty wellness committee, which created an anonymous survey with quantitative and qualitative components. The aim of the qualitative survey was to assess providers' major barriers to wellbeing and suggestions for improvement. In this study, the qualitative responses were analyzed using a grounded theory approach. The first reviewer used inductive and deductive strategies to encode statements and then generate overall categories for barriers to well-being. A second reviewer independently assigned survey responses to the categories generated by the first reviewer to determine inter-reviewer reliability. Discrepancies were resolved via discussion between the reviewers and the PI.

RESULTS: The inter-rater reliability was 49%. The most often cited factors contributing to provider burnout in order of frequency were lack of teamwork and communication, poor work flow, insufficient staffing, malfunctioning equipment, limited work space, and staff not functioning at the top of their licenses. Examples highlighting limited space, low staff functioning, and equipment malfunction include: "Space cramped, difficult to find space to informally gather as team", "I am often doing things outside

the scope of my job...but most of the rest of the non-physician staff view their roles as having very clear boundaries", and "A provider should not be looking for staples, fixing printers and rooming patients." Other barriers to well-being were misaligned leadership values, lack of continuing education resources, missing supplies, heavy workload, and insufficient rewards or incentives.

CONCLUSIONS: Faculty in an urban academic center reported a number of barriers to well-being on a qualitative survey. The main factors were poor team cohesiveness and work flow, environmental dysfunction, and insufficient staffing. Limitations of the study include small sample size, qualitative analysis, and lack of generalizability to other clinics. However the utility of this analysis is that it can by hypothesis generating for future quantitative work, and it can provide ideas for potential interventions to improve well-being for faculty in this clinic.

BEHAVIORAL HEALTH INTEGRATION IN VA PATIENT-CENTERED MEDICAL HOMES AND CLINICAL QUALITY OF MENTAL HEALTH CARE

Lucinda B. Leung^{1, 6}; Edward P. Post²; Erin L. Jaske³; Kenneth B. Wells⁴; Lisa V. Rubenstein⁵. ¹UCLA David Geffen School of Medicine & West LA VA Medical Center, Los Angeles, CA; ²VA Ann Arbor Healthcare System and University of Michigan, Ann Arbor, MI; ³Department of Veteran Affairs, Seattle, WA; ⁴UCLA, Los Angeles, CA; ⁵RAND and UCLA, Medford, OR; ⁶VA Greater Los Angeles, Los Angeles, CA. (Control ID #3179178)

BACKGROUND: Behavioral health integration in primary care is effective but challenging to disseminate and implement in healthcare systems. Over the past decade, the Primary Care-Mental Health Integration (PC-MHI) (i.e., care management, specialist collaborative care) and Patient Aligned Care Teams (PACT) (i.e., patient-centered medical home) initiatives transformed VA primary care clinics nationally into team-based care models to improve care for patients with psychiatric conditions. With increasing use of PC-MHI services over time, mental health care has accordingly shifted from specialty to PACT/primary care settings. We examined the combined effects of PC-MHI and PACT initiatives on quality of mental health care among VA primary care patients.

METHODS: We examined 828,050 primary care patients in 396 VA clinics mandated to offer PC-MHI services nationally (10/1/2013-9/30/2016). We calculated each clinic's PC-MHI penetration (i.e., the proportion of assigned primary care patients seen by a PC-MHI provider) and PACT implementation Progress Index (PI²) (i.e., measure of core PACT components [e.g., access, care coordination]) annually. Trained chart abstractors reviewed patient records for 11 process quality measures for psychiatric illness screening and management. In multilevel logistic regressions, we used clinic PC-MHI penetration to predict odds of meeting each quality measure, controlling for PI², regional healthcare system, clinic characteristics (e.g., size, rurality), and patient characteristics (e.g., age, gender).

RESULTS: Clinic screening rates for depression, post-traumatic stress disorder (PTSD), and alcohol misuse were high (on average, 96%, 99%, and 97%). Averages rates of clinician follow-up within 24 hours following abnormal screening were 64% (depression), 79% (PTSD), and 79% (alcohol misuse). In adjusted models, there were no PC-MHI or PI² effects observed among all mental health care quality indicators. There were no observed differences in care quality due to differences in gender, racial-ethnicity, homelessness, physical comorbidity, and serious mental illness. There were slight improvements to care quality related to patient age—timely follow-up of abnormal depression (Odds ratio[OR] = 1.01; p=.04) and PTSD (OR=1.01;p=.01) screening).

CONCLUSIONS: Although mental health treatment uptake has historically been poor in primary care, VA primary care patients continue to receive high quality mental health care (i.e., screening and timely follow-up). Without changing care quality, PC-MHI actively engaged more patients in care and reduced their reliance on specialty-based mental health

resources. We observed no differences in VA clinical care quality for patients of racial-ethnic minorities, nor for vulnerable patients (i.e., homeless, serious mental illness). Results examining VA's national dissemination of PC-MHI and PACT models highlight remaining mental health quality gaps and encourage continued model optimization to improve mental health care processes in primary care.

BEYOND THE BOOM: HEPATITIS C AND PEOPLE WHO INJECT DRUGS AT A SUBURBAN TERTIARY ACADEMIC MEDICAL CENTER 2016-2017

Kerim Odekon; Kalie L. Smith; Silvia L. Bronson; Luis A. Marcos. Stony Brook Medicine, Stony Brook, NY. (Control ID #3184694)

BACKGROUND: In 2004, adults aged 40-60, the 1945-1965 "Baby Boomer" birth cohort comprised 74% of NYS Hepatitis C (HCV) cases. By 2014, a bi-modal distribution emerged with Baby Boomers' share of HCV cases falling to 45.1%, and a new second peak of 20-40-year olds accounting for 38% of all HCV cases (2016 NYS DOH HIV Epidemiological Profile). In 2016 Stony Brook Hospital, a Tertiary Academic Hospital in Long Island NY, instituted a successful opt-out HCV screening and linkage to care initiative targeted to all persons born between 1945-1965. Long Island (comprising Nassau and Suffolk Counties) is an epicenter of the national opioid use and overdose epidemic. This study aims to look beyond Baby Boomers to quantify Hepatitis C screening rates for high risk and hard to reach suburban people who inject drugs (PWID) born after 1965.

METHODS: This study is a retrospective chart review 1/1/2016-11/30/2017 at Stony Brook University Hospital to identify Opioid Related Visits (ORV) and patients with a history of injection drug use. Charts were selected based on discharge ICD-10 codes related to opioid use. ER visits and hospital admissions were classified as ORV if associated with non-prescribed opioid use and 1) infection, 2) overdose, and/or 3) altered mental status. Individual charts were electronically queried using chart search function for the following keywords: Heroin, Cocaine, IVDA, IVDU or IV Drug to identify people with a hospital visit related to non-prescribed opioid use and/or history of injection drug use.

RESULTS: This study identified 1,030 Opioid Related Hospital Visits made by 684 unique people born after 1965 with a history of injection drug use. Only 24% of these individuals had any hepatitis C testing. 57% of these visits were for opioid overdose. For individuals who presented with an opioid overdose and documented history of injection drug use, only 19% had a hepatitis C test on record within the study period. Among this group, testing was more frequently associated with age and female gender, with only 15% of men aged 18-29 having any hepatitis C testing compared to 32% of women aged 30-44 and 45-51.

CONCLUSIONS: In July 2018, NYS Governor Cuomo announced a declaration to "end hepatitis C in New York State." The CDC recommends testing anyone who has injected drugs for HCV. The relatively low HCV screening rates for young people with a recent Opioid Related Visit and history of injection drug use suggests the need to expand HCV screening programs to target PWID as a necessary first step towards eradicating HCV virus in Long Island. Stigma around injection drug use, along with suburban geography pose unique challenges for outreach, screening, harm reduction, and treatment. Healthcare facilities must move beyond Baby Boomers and target screening and harm reduction efforts towards people who inject drugs to eradicate Hepatitis C.

BLENDED COLLABORATIVE CARE FOR TREATING SYSTOLIC HEART FAILURE AND CO-MORBID DEPRESSION: 12-MONTH PRIMARY OUTCOMES FROM THE HOPEFUL HEART TRIAL

Bruce L. Rollman¹; Amy M. Anderson¹; Kaleb Abebe¹; Kwonho Jeong¹; Bea Herbeck Belnap¹; Ravi Ramani²; Matthew Muldoon²; Jordan F. Karp¹.

¹University of Pittsburgh, Pittsburgh, PA; ²UPMC, Pittsburgh, PA. (Control ID #3185822)

BACKGROUND: Heart failure (HF) affects 6.6 million Americans with over 650,000 newly diagnosed cases and 330,000 deaths annually. Yet despite improvements in care, HF mortality is essentially unchanged in recent years. One potential reason is depression. It is co-morbid in nearly 40% of hospitalized HF patients and linked to reduced health-related quality of life (HRQoL) and increased mortality, but often goes untreated. The NHLBI-funded *Hopeful Heart Trial* is the first study to evaluate the impact of a collaborative care program for treating depression in HF patients.

METHODS: From 3/14 to 10/17, we screened inpatients with systolic HF (ejection fraction (EF) 45%) and NYHA class II-IV symptoms for depression using the Patient Health Questionnaire (PHQ-2) at 8 Pittsburgh-area hospitals. Two weeks post-discharge, we telephoned screen-positive patients (PHQ-2 (+)) to administer the PHQ-9 and randomized those who scored 10 to either their PCPs' "usual care" (UC) or to one of two nurse-provided, 12-month telephone-delivered collaborative care programs for treating: (1) HF and depression ("blended"); or (2) HF alone (attention control (AC)). Study nurses met with clinician-investigators for weekly case review sessions and then gave treatment advice to patients and their PCPs. To facilitate comparisons, we also randomly selected a cohort of non-depressed HF patients (PHQ-2(-)/PHQ-9 <5). At baseline, we collected sociodemographic and clinical data, and then monitored outcomes through periodic blinded telephone assessments and vital status determination.

RESULTS: Of the 756 HF patients recruited (629 depressed; 127 non-depressed; mean age: 64, 56% male, 73% White, mean EF 28%), those depressed had worse mental HRQoL (SF-12 MCS, mean: 40.1 vs. 60.5), physical function (Kansas City Cardiomyopathy Questionnaire): 40.5 vs. 76.8), and mood (PROMIS Depression: 60.0 vs. 41.8) than those non-depressed (all P<0.001), but were otherwise similar medically. Compared to UC, "blended" care patients reported a 0.34 ES improvement on the SF-12 MCS, our primary outcome measure (95% CI: 0.13-0.57), and 0.47 ES improvement on the PROMIS-D (0.72-0.22) at 12-months. Compared to AC, "blended" care patients also reported improved PROMIS-D (0.24 ES; 0.44-0.04), but not SF-12 MCS scores (0.09 ES; P=0.33). We confirmed 12-month vital status on all 756 patients and identified 95 deaths (82 depressed, 13 non-depressed); all-cause mortality for "blended", AC, UC, and non-depressed control patients was similar at 0.13, 0.14, 0.15, and 0.10 per person-year of observation, respectively ("blended" vs. AC: P=0.86; "blended" vs. UC: P=0.65; baseline depressed vs. nondepressed: P=0.39).

CONCLUSIONS: "Blended" collaborative care for treating both HF and depression improves HRQoL and mood symptoms more than physicians' UC at 12-months following hospitalization. Analyses are ongoing and we will present additional data on the impact of our interventions on health services utilization, mortality, and other outcomes.

BRCA TESTING IN MASSACHUSETTS AMONG WOMEN WITH PRIVATE INSURANCE OR MEDICAID, 2011-2015

Lydia E. Pace¹; Christopher F. Baum²; Krisztina Horvath²; Sahitya Raja³; Jessica Cohen⁴; Summer S. Hawkins². ¹Brigham and Women's Hospital, Boston, MA; ²Boston College, Chestnut Hill, MA; ³Brigham and Women's Hospital, Somerville, MA; ⁴Harvard T.H. Chan School of Public Health, Boston, MA. (Control ID #3185293)

BACKGROUND: There are growing concerns about inequitable access to and uptake of genetic medicine in the United States. BRCA1/2 testing has increased among privately-insured women, likely due to declining test costs, increased public awareness, and the Affordable Care Act's requirement that most private insurers cover testing without cost-sharing for high-risk women. Select state Medicaid programs cover BRCA testing, including Massachusetts' Medicaid program, MassHealth, but BRCA testing rates among Medicaid-insured women have been very rarely examined. We compared rates and trends in BRCA testing from 2011-2015 in Massachusetts between privately-insured and MassHealth- insured women.

METHODS: We used the Massachusetts All-Payer Claims Database to identify insurance claims for BRCA tests between January 1, 2011 and June 30, 2015 among women aged 18-64 with private insurance or MassHealth who had at least 12 months of continuous insurance enrollment before any BRCA claim. We identified whether women had breast or ovarian cancer as identified in ICD9/10 codes within 12 months before testing. We calculated monthly testing rates and mean monthly testing rates per year. We calculated absolute and relative differences in mean monthly rates between privately-insured and MassHealth-insured women and used linear trend modeling to examine trends in relative rate differences across years. Our study was considered exempt by the Boston College Institutional Review Board.

RESULTS: Overall, testing rates were lower among MassHealth-insured women compared with privately-insured women in all years, but mean monthly rates increased from 3.7 per 100,000 in 2011 to 14.7 per 100,000 in 2015 among MassHealth-insured women and from 9.3 to 18.4 per 100,000 in privately-insured women. The absolute mean monthly rate difference between privately- versus MassHealth-insured women declined from 5.6/100,000 (2011) to 3.8/100,000 (2015). The relative difference declined from 2.5 to 1.3, converging by 31% per year (p<.001). Trends and differences between groups varied by age. Among women aged 18-34, by 2015 the BRCA testing rate among MassHealth-insured women (7.9/100,000) was higher than among privately-insured women (5.1/100,000). The proportion of women without breast or ovarian cancer diagnoses obtaining BRCA testing was stable at 6% in both groups across years.

CONCLUSIONS: From 2011-2015, BRCA1/2 testing rates were lower among MassHealth-insured women compared with privately-insured women in Massachusetts. However, the difference decreased over time, and the difference was smaller among younger women. Our study suggests that in Massachusetts BRCA testing is not utilized equally among publicly- and privately-insured populations, though this gap may be narrowing. Future research should investigate contributing factors and examine other states.

BREAST CANCER SCREENING OUTCOMES USING DIGITAL BREAST TOMOSYNTHESIS: EVIDENCE FROM A CONTEMPORARY COHORT

Ilana B. Richman¹; Jessica R. Hoag²; Kelly A. Kyanko³; Xiao Xu⁴; Regina Hooley¹; Susan Busch²; Cary Gross¹. ¹Yale School of Medicine, New Haven, CT; ²Yale University, New Haven, CT; ³NYU School of Medicine, New York, NY; ⁴Yale University School of Medicine, New Haven, CT. (Control ID #3185799)

BACKGROUND: Digital mammography has imperfect sensitivity and specificity for detecting breast cancer. Digital breast tomosynthesis (DBT) may improve upon 2D mammography by reducing the need for subsequent imaging (known as recall) and improving cancer detection. DBT has been rapidly adopted, but whether the benefits reported in early studies of DBT are generalizable to the broader populations in which the technology is now used is not known. The goal of this study was to compare the effectiveness of DBT versus 2D mammography for breast cancer screening in a large contemporary population.

METHODS: We identified DBT and 2D screening mammograms from administrative claims data using a validated algorithm. We used data from the Blue Cross Blue Shield Axis, a large commercial claims database accessed via secure portal. Screening outcomes included recall (defined as subsequent imaging), biopsy, and cancer detection following screening. Screen detected cancers were defined according to a validated algorithm as invasive cancers detected within 120 days of screening. We also evaluated the rate of potential interval cancers, defined as cancers diagnosed between 120 and 365 days after

screening. We used multivariable models to compare screening outcomes among women screened with DBT versus 2D mammography, adjusting for age, hospital referral region, residence in a metropolitan area, year, and time since last mammogram. We also performed age-stratified analyses.

RESULTS: Our sample included 2,460,359 women who underwent mammography between 1/1/2015 and 12/31/2016 across all 50 states. Overall, 22% of screening exams used DBT. In adjusted analyses, DBT was not associated with a difference in recall rate compared to 2D mammography (121 vs 119 per 1000 screening exams, $p=0.27$). DBT was, however, associated with a higher biopsy rate (23 vs 18 per 1000 exams, $p<0.001$) and a higher cancer detection rate (4.1 vs 3.0 per 1000 exams, $p=<0.001$). Despite a higher cancer detection rate, DBT was not associated with a reduction in potential interval cancers compared to 2D mammography (1.3 vs 1.2 per 1000 exams, $p=0.007$). In age stratified analyses, results were similar across age groups.

CONCLUSIONS: Consistent with prior studies, we found that DBT is associated with a higher cancer detection rate compared to 2D mammography. In contrast to previous studies, though, we found that DBT did not reduce recall and was associated with a higher biopsy rate. Our findings have implications for the value of DBT, which may more effectively detect breast cancer, but is more expensive than 2D mammography and may generate additional invasive testing.

BUILDING A PARTNERSHIP TO IMPROVE HOSPITAL CARE AND CARE TRANSITIONS FOR PERSONS EXPERIENCING HOMELESSNESS

Sarah A. Stella^{1, 2}; Lisa Thompson³; Tammy Bellofatto³; Sarah E. Leslie¹; Ellen Sarcone^{1, 2}; Erin Bredenberg²; Lilia Cervantes^{1, 2}. ¹Denver Health, Denver, CO; ²University of Colorado School of Medicine, Denver, CO; ³Colorado Coalition for the Homeless, Denver, CO. (Control ID #3162606)

BACKGROUND: Research which includes the perspectives of persons experiencing homelessness is needed to inform the development of meaningful interventions to improve hospital care and care transitions for this group. Our objective was to establish a Community Advisory Panel (CAP) to better understand the perceptions of people experiencing homelessness and key community stakeholders with respect to hospitalization and care transitions, and to develop a shared vision regarding opportunities/priorities for improvement through future programs and research.

METHODS: To establish our CAP, we partnered with leaders at the Colorado Coalition for the Homeless, a non-profit organization that provides housing, integrated healthcare, and other supportive services to those experiencing homelessness. We developed mutual partnership goals and a framework for shared oversight. We jointly recruited CAP participants, seeking to include both individuals experiencing homelessness, and community stakeholders with relevant experience providing care to this group. Additional selection criteria were: age 18 years or older; English-speaking, and able to attend the majority of 6 panel meetings. Participants received a meal and small stipend for their participation at meetings. All meetings were jointly facilitated by lead academic and community partners. Plans were developed *a priori* with input from community partners, and refined through analysis of emerging themes and through shared decision-making with participants. With participants' consent, meetings were audio-recorded and transcribed verbatim to assist the synthetization of information, iterative refinement of concepts, and qualitative analysis. De-identified transcripts were coded in Atlas.ti utilizing codes derived *a priori* from theory and inductively through identifying emerging themes.

RESULTS: A total of 12 individuals were recruited for the CAP. They included: 6 individuals with lived experience of homelessness who had direct experience with hospitalization and care transitions; and 6 community stakeholders with relevant experience caring for homeless individuals while hospitalized or in the community. The CAP met 6 times from July 2018- January 2019. We identified 4 important themes: 1) trauma encountered through the everyday experience of homelessness and/or through healthcare interactions; 2) empathy and other aspects of the patient-physician relationship; 3) moral distress and burnout among healthcare providers and other personnel caring for persons experiencing homelessness; 4) and the availability, coordination, and integration of services after discharge to respite, shelters or other locations.

CONCLUSIONS: Engaging individuals with lived experience of homelessness and key community stakeholders in research results in a better understanding community needs and priorities with respect to hospital care and care transitions, and thus more meaningful translational research to address the significant, known health inequities faced by this community.

BUILDING AN AMBULATORY INFRASTRUCTURE TO REDUCE HOSPITALIZATIONS AMONG CHRONIC KIDNEY DISEASE PATIENTS: A SYSTEM-WIDE VALUE APPROACH TO HIGH COST POPULATIONS

Reshma Gupta^{2, 1}; Samuel A. Skootsky¹; Katherine L. Kahn²; Lucia Chen²; Sitaram Vangala²; James Wilson². ¹UCLA, Los Angeles, CA; ²David Geffen School of Medicine at UCLA, Los Angeles, CA. (Control ID #3161044)

BACKGROUND: Chronic kidney disease (CKD) is a leading cause of spending nationally. With an imperative to provide accountable care across ambulatory and inpatient settings, there is a shift toward risk-sharing contracts that reward reductions in total spending achieved through coordinated, quality care. The alignment of primary and specialty care teams provides strategies to facilitate patients receiving timely, needed services in the most appropriate, cost-effective setting. As part of an enterprise-wide transformation to improve healthcare value, UCLA identified condition-specific, high cost patients and adapted a new patient-centered approach to improve quality and care coordination. Recognizing that advanced (stage 4 or 5) CKD patients experienced frequent emergent hospitalizations to initiate dialysis and treat catheter dysfunction, UCLA Health implemented a pathway for advanced CKD patients attributed to the UCLA primary care network. We evaluated the impact of this initiative on health system utilization.

METHODS: Between October and December 2016, an interdisciplinary, multispecialty team co-created and implemented care pathways for the advanced CKD patient population that involved: 1) clinically meaningful longitudinal data management, 2) proactive care management to align clinical and social service care across primary and multi-specialty settings, and 3) strategies to enhance access to lower-cost interventional radiology care sites. We used internal EHR and claims data across eight payers to define utilization outcomes (i.e. hospitalizations, inpatient bed days, 30-day all-cause readmissions, and emergency department (ED) visits). Using an 18-month pre-intervention period to control for baseline bias, we conducted descriptive and interrupted time series regression analyses, to evaluate the impact of the intervention on outcomes.

RESULTS: Of 1442 advanced CKD patients, the estimated rate of hospitalizations per 1000 patient-years was 712 at the beginning of the pre-intervention period (95% CI: 610-832), and declined at

an estimated monthly rate of 2% during this period (95% CI: 0.8%-3.2%). By contrast, the estimated rate of hospitalizations per 1000 patient-years declined at an estimated monthly rate of 5% during the post-intervention period (95% CI: 3.4%-7.4%). This acceleration in the monthly rate of decline after the intervention was statistically significant ($p=0.004$). CKD patients also had a nonsignificant 4% faster reduction in monthly inpatient bed days (4.8% [95% CI: 2.5%-7.0%] versus 8.6% [95% CI: 4.7%-12.3%], $p = 0.10$) and 2% faster reduction in ED visits (0.9% [95% CI: -0.1%-2.0%] versus 2.7% [95% CI: 0.9%-4.3%], $p = 0.09$) from pre- to post-intervention periods. There was no difference in 30-day readmissions ($p= 0.26$).

CONCLUSIONS: By creating care pathways that link primary and specialty care teams with increased ambulatory infrastructure, health systems have potential to enhance care coordination in association with reductions in health costs.

CAN A LARGE SCALE QUALITY IMPROVEMENT INTERVENTION DESIGNED TO REDUCE CARDIOVASCULAR RISK ALSO ATTENUATE BLACK -WHITE DISPARITIES IN HYPERTENSION CONTROL?

Samuel Cykert¹; Crystal W. Cene¹; Darren Dewalt¹; Justin Trogdon². ¹University of North Carolina, Chapel Hill, NC; ²UNC Gillings School of Global Public Health, Chapel Hill, NC. (Control ID #3183099)

BACKGROUND: Hypertension affects more than 70 million people in the US and increases the risk of all-cause mortality, heart disease, stroke, and chronic kidney disease. There are significant racial disparities in hypertension control. Compared to Whites, Blacks have a higher prevalence of hypertension (40.1% vs. 27.4%). Additionally, they are less likely to achieve blood pressure control. The lack of control in the Black population accounts for half the excess cardiovascular disease (CVD) mortality observed in Blacks and 5% of the overall racial difference in potential life-years lost. Heart Health Now (HHN) is an AHRQ sponsored initiative designed to reduce CVD risk for adults served by small, North Carolina primary care practices. This report examines the effect of this intervention on hypertension disparities.

METHODS: We conducted a pre-post evaluation of change in blood pressure control comparing White with Black patients. Clinical data were derived from daily electronic health record uploads from 219 practices. To be eligible, practices had to have 10 or fewer clinicians. The intervention consisted of provision of onsite practice facilitation to implement QI strategies and use of a CVD population management dashboard. Adult patients with an ICD-9 or ICD-10 diagnosis of hypertension aged 18 to 85 years were included. We examined the overall hypertension control (SBP < 140 and DBP < 90) gap between Black and White patients at baseline, the percentage of practices that had gaps, and whether these differences changed after the 12-month intervention. The analyses controlled for practice demographics, patient centered medical home status, practice disruptions, and measured change capacity.

RESULTS: 219 practice sites caring for 116,952 White and 46,406 Black hypertensive patients. Average # providers per site was 7. Fifty-nine% of practices were clinician-owned; 29% were federally qualified health centers; 52% were rural. The average payer mix was Medicare 28%, Medicaid 16%, dual 10%, uninsured 12%, commercial insurance 30%, and "other" 4%. Clinicians averaged 21 patient visits per day. At baseline, 57.8% of Black patients' hypertension was controlled compared to 64.2% of Whites ($p < 0.001$). Post-intervention these proportions were 60.1% and 66.3%, respectively ($p < 0.001$). While hypertension control for Blacks improved (over 1000 individuals newly controlled), racial disparity remained. On the practice level, there was no racial difference

in hypertension control in 22% of practices at baseline; the majority (78%) of practices had a disparity favoring Whites ($p < 0.001$) that was unchanged post-intervention.

CONCLUSIONS: Although widespread implementation of an intensive, practice-based, QI intervention improved hypertension control for Black and White patients, it did not reduce disparities. Within practice disparities were predominant. Research examining practices with no disparities and devising socio-culturally tailored strategies appear to be necessary next steps to close racial gaps.

CAN AN INTENSIVE AMBULATORY CARE INTERVENTION IMPROVE THE EXPERIENCE OF HIGH-UTILIZING PATIENTS?: 6-MONTH OUTCOMES OF THE SUMMIT RANDOMIZED CONTROLLED TRIAL.

Brian Chan^{1, 2}; Samuel T. Edwards^{4, 1}; Matthew Mitchell²; Christina Nicolaïdis^{3, 5}; Devan Kansagara^{4, 5}; Philip T. Korthuis⁵; Somnath Saha⁴. ¹OHSU, Portland, OR; ²Central City Concern, Portland, OR; ³Portland State University, Portland, OR; ⁴Portland VA Medical Center, Portland, OR; ⁵Oregon Health & Science University, Portland, OR. (Control ID #3186182)

BACKGROUND: People experiencing homelessness, co-morbid chronic medical conditions, and substance use disorder (SUD) make up a disproportionate number of high-cost, high-need patients at risk of frequent acute care utilization. Intensive ambulatory care unit ("A-ICU") interventions aim to improve patient engagement, patient experience and quality of care, and reduce high-cost utilization.

METHODS: This is a preliminary analysis of a randomized trial of SUMMIT, an A-ICU for high-utilizers at a federally qualified health center that serves patients with high rates of homelessness and substance use. SUMMIT is a stand-alone A-ICU team consisting of care coordinators, an addictions-boarded physician, social workers, complex care nurse, pharmacist, and team manager, with a low staff-to-patient ratio and increased appointment flexibility. Patients were eligible to be referred to SUMMIT if they had 1+ hospitalizations in the prior 6 months, or had 2+ chronic medical conditions and/or active substance use or a mental health condition. After consent and a baseline survey, patients were randomized to enroll in SUMMIT immediately or to join the SUMMIT wait list while remaining in usual care (patient-centered medical home model). We assessed patient experience and functional status using ambulatory consumer assessment of healthcare providers and systems (CAHPS) and the 12-item short form survey (SF-12) at baseline and at six months. We also examined average number of hospital admissions at 6 months, average length of stay (LOS), emergency department (ED) visits, primary care visits, and behavioral health visits.

RESULTS: Of the first 102 patients enrolled, 52% (n=53) were randomized to SUMMIT immediately. Average age was 53.8 years (+/-10.1), the majority (64.7%) were male, 87.3% had experienced homelessness, 56.9% had a SUD history. Baseline utilization for enrolled patients was 3.0 admissions, 4.5 ED visits, 8.1 primary care visits, and 2.9 behavioral health visits in the prior 6 months. At six months patients in SUMMIT reported improved CAHPS ratings in communication (81% "top-box" vs 63%, $P=.001$) and care coordination (60% vs 43%, $P=0.01$), and improved mental health composite SF-12 scores (48.1 vs 41.8, $P=0.006$) versus control patients. The SUMMIT patients had more PCP visits (14.1 vs 5.8, $P<.001$) and tended to experience fewer hospitalizations (1.8 vs 2.1, $P=0.25$), shorter LOS (13.0 vs 16.0, $P=0.2$), more ED visits 3.7 vs 2.8, $P=0.36$), and more behavioral health visits (5.8 vs 5.1, $P=0.1$).

CONCLUSIONS: The SUMMIT program improved patient experience, improved mental health symptoms, and increased primary care engagement at six months. We did not observe significant changes in inpatient or ED utilization, possibly due to our small sample size and limited time frame. Future analyses will evaluate 12-month outcomes and will assess whether certain subgroups of high-utilizing patients benefit most from A-ICU care.

CAN AN INTERPROFESSIONAL EDUCATION INITIATIVE AFFECT QUALITY OF CARE AND HEALTH CARE UTILIZATION?

Samuel T. Edwards¹; Elizabeth R. Hooker²; Rebecca Brienza³; Bridget O'Brien¹⁰; Hyunjee Kim⁴; Stuart Gilman⁵; Lillian Gelberg⁶; Sarah Shull⁷; Nancy Harada⁵; Meike Niederhausen²; Samuel King⁵; Elizabeth Hulen¹¹; Mamta K. Singh⁸; Anais Tuepker⁹. ¹Boston VA Healthcare System, Boston, MA; ²Portland VA Medical Center, Portland, OR; ³VA Connecticut Healthcare System, West Haven, CT; ⁴Oregon Health & Science University, Portland, OR; ⁵US Dept of Veterans Affairs, Washington, DC; ⁶UCLA, Los Angeles, CA; ⁷Portland VA, Portland, OR; ⁸Case Western Reserve University, Cleveland, OH; ⁹VA Portland Health Care System/Oregon Health and Science University, Portland, OR; ¹⁰UCSF, San Francisco, CA; ¹¹VA Portland Health Care System, Portland, OR. (Control ID #3185305)

BACKGROUND: Interprofessional education (IPE) has been shown to improve learner proficiencies, but the effect of IPE interventions on patient level outcomes is unknown. The Department of Veterans Affairs' (VA) Centers of Excellence in Primary Care Education (CoEPCE) is a multi-site IPE initiative that integrates the post graduate training of physicians, nurse practitioners, pharmacists and psychologists in VA academic primary care clinics. In this study, we estimated the impact of CoEPCE implementation on quality of care and health care utilization.

METHODS: We performed a retrospective cohort study using VA electronic health record data. We identified patients cared for by clinician trainees in five CoEPCE sites, and patients cared for by clinician trainees in regionally matched non-CoEPCE academic primary care clinics, from 7/1/2008 - 6/30/2015. Outcomes included seven measures of quality of care: annual hemoglobin A1c [HbA1c], poor A1c control [$<9\%$ or unmeasured], and annual renal test in diabetes mellitus; prescription of a high risk medication in patients >65 years; hypertension control ($<140/90$); timely mental health referrals, and primary care mental health integrated visits; and 3 measures of health care utilization: emergency department (ED) visits, all cause hospitalizations and hospitalizations for ambulatory care sensitive conditions (ACSC). We compared changes in outcomes from the three years before (7/1/2008-6/30/2011) to the four years after (7/1/2011-6/30/2015) initiative launch, between CoEPCE patients and non CoEPCE patients using a difference in differences approach. Models adjusted for demographics, comorbidities, year and years under VA care, and standard errors were clustered by site. Alternative comparison groups were used as sensitivity analyses.

RESULTS: We identified 49,279 CoEPCE clinician trainee patient-years (mean age 59.3 [sd 15.2] years, mean Elixhauser comorbidity score 12.9 [sd 15.1]) and 58,407 non CoEPCE clinician trainee patient-years (mean age 61.8 [sd 15.3] years, mean Elixhauser comorbidity score 13.8 [sd 15.7]). Compared to non-CoEPCE patients, CoEPCE patients had improvements in the proportion with poor control of HbA1c (-4.6 percentage points [pp], $p<0.001$), annual renal testing (+3.2 pp, $p=0.016$), patients over age 65 receiving a high risk medication (-2.3 pp, $p=0.005$) and timely mental health referrals (+1.6 pp, $p=0.002$). CoEPCE patients had fewer ED visits (proportion with >1 ED visit in year -3.7 pp, $p<0.001$), hospitalizations (-0.8 pp had >1 hospitalization in year, $p=0.007$), and hospitalizations for an ACSC (-0.4 pp, $p=0.014$). Sensitivity analyses with alternative comparison groups yielded similar results.

CONCLUSIONS: The CoEPCE initiative was associated with improved quality of care and reduced health care utilization. Interprofessional education can impact patient level outcomes and may potentiate delivery system reform efforts.

CAN PATIENT-PROVIDER INTERPERSONAL INTERVENTIONS ACHIEVE THE QUADRUPLE AIM OF HEALTH CARE?: A SYSTEMATIC REVIEW

Marie Haverfield¹; Aaron A. Tierney²; Rachel Schwartz³; Michelle Bass¹; Cati Brown-Johnson⁴; Dani L. Zions⁵; Nadia Safaeinili³; Jonathan G. Shaw⁵; Sonoo Thadaney¹; Gabriella Piccininni⁶; Karl Lorenz⁷; Steven Asch⁷; Abraham Vergheese¹; Donna M. Zulman⁸. ¹Stanford University, Menlo Park, CA;

²Stanford University School of Medicine, Mountain View, CA; ³Stanford University, Stanford, CA; ⁴Stanford School of Medicine, Stanford, CA; ⁵Stanford University School of Medicine, Stanford, CA; ⁶Stanford University, Toronto, ON, Canada; ⁷VA/Stanford, Menlo Park, CA; ⁸Stanford University and VA Palo Alto, Stanford, CA. (Control ID #3166752)

BACKGROUND: Human connection is at the heart of medical care. The extent to which such connection can be taught or improved has been the subject of much research, but questions remain as to the effectiveness of these interventions. We synthesized the evidence for interpersonal interventions to improve patient-provider interactions and downstream health outcomes.

METHODS: We searched PubMed, EMBASE, and PsycInfo (January 1997 to August 2017) for randomized controlled trials and controlled observational studies that examined the association between patient-provider interpersonal interventions and at least one outcome measure of the Quadruple Aim. We also mined applicable systematic reviews to identify additional relevant citations. Using Covidence, abstractors worked in pairs to cull information about the content and methods of each article, assessed the quality of research, and graded levels of evidence. We characterized the evidence related to intervention target (provider-only vs. provider-patient dyad), the objective of the intervention, the type and duration of intervention training, and the Quadruple Aim outcomes.

RESULTS: 77 out of 21,835 studies met all design and outcome inclusion criteria. The methodological quality of research was moderate-to-high for the majority of studies. Most interventions focused on enhancing provider communication skills (29%). Among the 44 studies that reported a positive patient experience outcome, 50% used a provider-focused intervention, suggesting patients do not have to be involved in the intervention to improve their perceptions of care. Population health was often improved following an interpersonal intervention, and studies measuring improvements in patient health often corresponded with improved patient experience. Similarly, provider well-being (e.g., burnout, communication confidence, stress) improved from enhanced patient-provider interpersonal interactions. One of the most common types of interventions that positively influenced provider experience was clinician training using a communication content focus, which was associated with improvements in communication, satisfaction, and perceived provider friendliness. Few studies evaluated overall cost outcomes, but several reported reduced utilization and prescription rates. Few interventions increased visit length, and interventions with lower demands on provider time and effort were generally as effective as those with higher demands on provider time.

CONCLUSIONS: We found good evidence that interpersonal interventions aimed at improving patient-provider interactions also improve patient and provider experience, and weaker evidence that they improved population health or cost. Quality improvement efforts might focus on simple low demand interventions, as they were equally effective.

CAPTURING THE REST: INPATIENT INTERVENTION STUDIES FOR NON-ADHERENT HOSPITALIZED WOMEN TO IMPROVE THEIR BREAST CANCER SCREENING ADHERENCE

Waseem Khaliq¹; Regina Landis²; Eric Howell²; Scott Wright³. ¹Johns Hopkins University School of Medicine, Ellicott city, MD; ²Johns Hopkins, Baltimore, MD; ³JHU SOM, Baltimore, MD. (Control ID #3150766)

BACKGROUND: More than a third of hospitalized women are overdue for breast cancer screening and at high risk for developing breast cancer. We evaluated the feasibility of two separate interventions for non-adherent hospitalized women to improve their adherence to breast cancer screening recommendation. First intervention consisted of inpatient breast cancer screening education, scheduling an outpatient mammography prior to hospital discharge, a reminder phone call and a small monetary incentive for screening test. The second intervention consisted of inpatient breast cancer screening education and offering inpatient screening mammography.

METHODS: For both intervention studies women aged 50-75 years who were hospitalized to a general medicine service and were non-adherent to breast cancer screening were approached for enrollment. Socio-demographic, reproductive history, family history for breast cancer, and medical comorbidities data was collected for all patients. Chi square and unpaired t-tests were utilized to compare characteristics among women who did and did not get screening.

RESULTS: First intervention was conducted among 30 hospitalized women who were non-adherent to breast cancer screening at Johns Hopkins Bayview Medical Center, the mean age for study population was 57.8 years, mean 5-year Gail risk score was 1.68, and 57% of women were African American. Only one third of the enrolled women (n=10) went to their pre-arranged appointments for screening mammography. Not feeling well enough after the hospitalization and not having insurance were reported as main reasons for missing the appointments. Second intervention was conducted among 101 hospitalized women non-adherent to breast cancer screening at Howard County General Hospital, the mean age for this study population was 59.2 years, mean 5-year Gail risk score was 1.63, and 29% of women were African American. More than two-third of the enrolled women (n=79) underwent in-patient screening mammography. All women who underwent screening mammography during inpatient stay were extremely satisfied. Neither the ordering hospitalists nor the nurses taking care of these women reported any concerns or misgiving. Convenience of having a screening mammography while in-patient stay was reported to be a facilitator of completing the screening test.

CONCLUSIONS: Although both interventions were successful in improving awareness and adherence to breast cancer screening, inpatient mammography intervention had much higher impact on breast cancer screening adherence. Because hospitalization creates the scenario wherein patients are in close proximity to healthcare resources, at the same time that they are reflecting upon their health status, strategies could be employed to counsel, educate, and motivate these patients towards health maintenance. Future studies need to evaluate the inpatient feasibility of other common cancer-screening tests to overcome the significant barriers to compliance with screening for hospitalized population.

CARDIOVASCULAR HEALTH OF FOREIGN-BORN VETERANS IN THE VETERANS HEALTH ADMINISTRATION

Karen Wang¹; Christine Ramsey³; Carol Oladele¹; Sally G. Haskell²; Cynthia Brandt¹. ¹Yale University School of Medicine, New Haven, CT; ²Yale University, VA CT, and VA Central Office, Madison, CT; ³Corporal Michael J. Crescenz Veterans Affairs Medical Center, Philadelphia, PA. (Control ID #3180109)

BACKGROUND: Foreign-born individuals have served in all major military conflicts, including recent conflicts in Iraq and Afghanistan. There are a half-million veterans who are foreign-born, yet we have limited knowledge about their health. Our objective is to describe the socio-demographic and cardiovascular-health risk factors and outcomes among the foreign-born veterans of the recent conflicts.

METHODS: We analyzed data from the Women Veterans Cohort Study, a study of current-era veterans who used Veterans Health Administration (VHA) services between September 11, 2001 and November 19, 2014. Our sample included veterans whose place of birth was identified as outside of the United States and its territories. We examined prevalence of socio-demographic and cardiovascular-health risk factors and outcomes by United Nations (UN) geographic regions using chi-squared tests. Risk factors included age, sex, race/ethnicity, marital status, education, obesity, smoking history, and diagnoses of diabetes, hypertension, major

depressive disorder (MDD), and post-traumatic stress disorder (PTSD). Outcomes were diagnosis of coronary artery disease (CAD), congestive heart failure (CHF), cardiovascular disease (CVD), and stroke.

RESULTS: Our sample included 66,940 veterans who are foreign-born (14% women; 55.7% aged 21-29; 28% white, 17.1% black, and 27.4% Hispanic). Over half were married and 98.6% had at least a high-school education. Thirty percent (N=20,440) had data on country of birth. Among these, 8.2% were born in North America, 33.2% in Central America, 38.6% in Asia, 18.1% in Europe, and 1.3% in Melanesia, Micronesia, and Polynesia. Almost 28% percent of all foreign-born veterans were obese, and 30% were current smokers. Four percent were diagnosed with diabetes; 9.6% with MDD; 13.1% with hypertension; and 26.5% with PTSD. Age, race/ethnic, and gender of Veterans differed significantly by region, as did the prevalence of obesity, smoking history, diabetes, hypertension, and PTSD ($p<0.001$ for all). Veterans from Melanesia, Micronesia, and Polynesia had the highest prevalence of obesity (54.9%) and current smoking along with Europe (43.3% for both). Prevalence of hypertension (24.4%) and diabetes (9.4%) were highest in veterans born in Asia; and prevalence of PTSD was highest in veterans from Central America (31.8%). Overall prevalence of cardiovascular outcomes among foreign born veterans were: CAD 0.77%, CHF 0.11%, CVD 0.24%, and stroke 0.4%. Prevalence of CAD differed significantly by region ($p<0.001$).

CONCLUSIONS: Foreign-born veterans originate from different regions of the world and are at risk for preventable cardiovascular outcomes. One tenth to one-third of individuals in specific regions had modifiable risk factors, such as obesity, current smoking, and hypertension. This VHA data presents a unique opportunity to further examine health differences between foreign-born and US-born individuals.

CARE FOR AMERICA'S ELDERLY AND DISABLED RELIES ON IMMIGRANT LABOR

Leah Zallman^{1, 2}; Karen Finnegan¹; David Himmelstein^{3, 2}; Stephanie Woolhandler^{3, 2}. ¹Institute for Community Health, Malden, MA; ²Cambridge Health Alliance/Harvard Medical School, Cambridge, MA; ³City University of New York at Hunter College, New York, NY. (Control ID #3184574)

BACKGROUND: As our nation wrestles with immigration policy and how to care for an aging population, data on immigrants' role in the provision of long term care can inform both debates. Previous studies have examined immigrants' role as direct care workers, but have not examined those hired by private households (or by non-medical facilities such as senior housing) to assist elderly and disabled persons, or undocumented immigrants' role in the provision of these services.

METHODS: We use detailed occupation and industry data from the Current Population Survey (CPS) 2018, which provides nationally representative data reflecting 2017 events. We estimate the number of immigrant health care workers, long-term care workers and non-formal caregivers, and direct care workers. We use a previously developed methodology to impute immigration status.

RESULTS: We find that immigrants accounted for 18.2% of all health care workers in 2017, and 23.5% of workers in long-term care and the non-formal caregiving sector. More than one quarter (27.5%) of direct care workers were immigrants and 30.3 % of nursing home housekeeping and maintenance workers were immigrants, over one third of whom were undocumented. Although legal noncitizen immigrants accounted for 5.2% of the U.S. population, they comprised 9.0% of direct care workers, including 16.0% of non-formal sector workers.

CONCLUSIONS: In light of the current and projected shortage of direct care workers, our finding that immigrants already fill a disproportionate share of such jobs suggests that policies curtailing immigration are likely to compromise the availability of care for elderly and disabled Americans.

CARE MANAGEMENT FOR THE EFFECTIVE USE OF OPIOIDS (CAMEO): A RANDOMIZED TRIAL

Matthew J. Bair^{1, 2}; Samantha D. Outcalt¹; James E. Slaven²; Kurt Kroenke³; Carol Kempf⁴; Alan Zillich⁴; Teresa Damush¹; Chandan Saha²; Dustin D. French⁵; Erin E. Krebs⁶. ¹VA Center for Health Information and Communication, Indianapolis, IN; ²Indiana University School of Medicine, Indianapolis, IN; ³Indiana University, Indianapolis, IN; ⁴Roudebush VA Medical Center, Indianapolis, IN; ⁵Northwestern U, Chicago, IL; ⁶Minneapolis VA Health Care System, Minneapolis, MN. (Control ID #3185091)

BACKGROUND: Chronic low back pain is common and accounts for an enormous burden in patient suffering, diminished quality of life, disability, and health care costs. Many options are available to treat chronic low back pain, yet management remains difficult. The objective of the CAMEO Trial was to compare the effectiveness of pharmacological treatment and optimization vs. cognitive behavioral therapy for Veterans with chronic lower back pain on chronic opioid therapy.

METHODS: CAMEO was designed as a 2-arm, randomized clinical trial. The study setting was 5 general medicine clinics at a Veteran Affairs Medical Center and 2 community based outpatient clinics. Participants included 261 Veterans with chronic low back pain of at least moderate intensity who were on chronic opioid therapy at baseline. Enrollment occurred from August 2011 to December 2014, with 12-month follow-up completed by December 2015. The pharmacological (PHARM) arm involved nurse care management focused on analgesic treatment and optimization according to an algorithm. The behavioral (BEHAV) arm involved cognitive behavioral therapy delivered by clinical psychologists. The primary outcomes were pain impact, pain intensity, and pain interference as assessed by the Brief Pain Inventory (BPI).

RESULTS: The mean age participants was 57.9 years, 92% men, 73% White and 21% Black. 131 participants in the PHARM arm and 130 participants in the BEHAV arm were included in the primary analysis. At 12 months, the adjusted mean decrease from baseline in the BPI total score (pain impact) was 0.64 points (Standard deviation [SD] = 0.22) in the BEHAV group and 1.14 points (SD = 0.23) in the PHARM group (between group difference of 0.5 points, p = 0.0423). Scores were adjusted for baseline BPI total score, depression (PHQ-9), and gender. At 12 months, BPI pain intensity decreased by 0.40 points in the BEHAV group (SD = 0.19) and 1.02 points (SD = 0.20) in the PHARM group (between group difference of 0.62, p = 0.0044). The mean decrease from baseline in the BPI interference score was 0.71 points in the BEHAV group and 1.19 points in the PHARM group (between group difference of 0.48 points; p = 0.0846). There were no differences in secondary outcomes (depression, anxiety, PTSD, and health-related quality of life) across study arms.

CONCLUSIONS: Both treatment groups improved, but improvement was modest. A nurse care management intervention focused on pharmacological management reduced pain impact and intensity more than a behavioral intervention involving cognitive behavioral therapy. While the between-group differences were statistically significant, these differences may not be clinically significant. To improve treatment effects combination therapy is likely needed, especially for patients with complex chronic low back pain.

CARE MANAGEMENT PLUS: TIME-LIMITED LONGITUDINAL RN CARE MANAGEMENT

Corinne Rhodes¹; Sarah LaMar³; Andrew Maier⁴; Susan C. Day². ¹University of Pennsylvania Health System, Philadelphia, PA; ²University of

Pennsylvania, Philadelphia, PA; ³Penn Medicine, Philadelphia, PA; ⁴UPenn, Philadelphia, PA, PA. (Control ID #3185836)

BACKGROUND: We developed and implemented a longitudinal, proactive care management (CM) program targeting our highest risk patients as part of Comprehensive Primary Care Plus (CPC+) Medicare innovation grant in 3 urban academic clinics. Goals were to decrease utilization and achieve patient and primary care provider (PCP) goals. We hypothesized decreased utilization during enrollment would persist after graduation.

METHODS: Our central CM model was overseen by a RN manager and physician lead. Patients enrolled in a 6-month intervention with a two-step process including EPIC risk score including registries, utilization, social determinants of health (SDH) proxy measures and then underwent PCP review. Care managers (CM) performed a standardized intake including modifiable barriers of care and collected patient centered goals. CM proactively followed patients and communicated to PCP or designated providers via EPIC and brief weekly meetings. Patients graduated at 6 months, sooner if not engaged, or extended enrollment at discretion of PCP. This interim analysis looks at 192 patients enrolled with 6 months of post-graduation utilization data. Descriptive data shows patients approached, enrolled, engaged, and graduated and completed goals with means and standard deviations (SD). We examined combined ED and hospital utilization by unadjusted and apriori adjusted longitudinal person-clustered mixed regression models. We randomly matched control patients with recent utilization at a 1:1 ratio by clinic, age, sex, race, and Charlson comorbidity score.

RESULTS: 326 patients were approached, 84 (25.8%) did not enroll; 30% of enrolled were not engaged and did not graduate, and 10% died, moved, or entered skilled care by end of intervention. Enrolled patients' mean age was 64.9 (SD 14.6), 60.9% female, 89.1% Black, 25.5% Medicaid or Managed Medicaid, with average Charlson score of 7.6 (SD 3.3). 175 (91.1%) set goals and 68.2% achieved a goal. Combined relative utilization decreased by 33.1% from 1.6 events 6 months prior, 1.07 events during 6-month enrollment and 1.09 events 6 months after enrollment, p<0.0001 for unadjusted and adjusted models. We matched patients with recent utilization by age, sex, clinic, race, and Charlson score. The model for the 190 matched patients showed no significant change in utilization during the same 6-month periods (unadjusted p=0.85; adjusted p=0.85). Combined models showed significant intervention status (p=0.0015) and intervention*time interaction (p=0.0058) in unadjusted and adjusted models.

CONCLUSIONS: Our central CM program reduced utilization by 33.1% during and after program graduation, with 68.2% of patients reaching a stated goal. Intervention patients had higher utilization at enrollment than matched control samples, which could indicate regression to mean, however control patients showed no regression to overall population mean from their initial utilization (mean utilization events for population =0.19 events SD 0.56).

CAREER CONSEQUENCES FOR MEDICAL STUDENTS EXPERIENCING SEXUAL HARASSMENT

Emmanuelle B. Yecies^{1, 2}; Melissa McNeil³. ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3185051)

BACKGROUND: Recent studies have demonstrated the high prevalence of sexual harassment in medicine, with 30% of female physicians and over 15% of medical students endorsing sexual harassment. There is also increasing recognition that the spectrum of sex discrimination includes microaggressions. However, it remains unclear what consequences sexual harassment has on the attitudes and career trajectories of women in the field of medicine. We aimed to identify the effect of sexual harassment on

student attitudes towards medicine and specialty choices.

METHODS: An in-person cross-sectional survey was administered to incoming interns at UPMC about their experience with sexual harassment in medical school. The survey was adapted from a previously-published validated instrument (Sexist MESS) and included questions about attitudes following the experience of sexual harassment. The Likert scale answers to these questions were analyzed using chi-squared statistics to determine differences between male and female respondents.

RESULTS: 185 graduates of U.S. medical schools returned the survey (100% response rate), with 182 completing both demographics and attitudes sections. Interns represented the full spectrum of specialties and graduated from medical schools across the country. 92 respondents identified as female, and 90 as male. The statement "Negative experiences related to my gender caused me to feel bad about coming to work" yielded answers of agree or strongly agree in 8.7% of women and 2.2% of men. 8.7% of women and 0% of men agreed with "Negative experiences related to my gender caused me to doubt my choice of medicine as a profession." 10.9% of women and 2.2% of men agreed with "Negative experiences related to my gender contributed to changing the specialty I pursued" ($p<0.001$ for all). Of those respondents who identified a specialty they switched from due to negative gender-related experiences, women most frequently identified surgical fields (5 of 9 responses). Men exclusively identified Obstetrics-Gynecology (3 of 3 responses).

CONCLUSIONS: Students of both genders reported career consequences to negative gender-related experiences. Women are four times more likely to report negative outcomes related to sexual harassment, and these experiences impact their specialty choices, particularly in surgical fields. Addressing sexual harassment in medical school and building strong support systems will be crucial to ensuring that students can thrive in all specialties.

CAREGIVER STRAIN IS ASSOCIATED WITH MEDICATION ADHERENCE AMONG CAREGIVERS WITH DIABETES: THE REASONS FOR GEOGRAPHIC AND RACIAL DIFFERENCES IN STROKE (REGARDS) STUDY

Alexandra King³; Joanna Bryan¹; Monika M. Safford¹; Catherine Riffin¹; Ronald Adelman¹; David Roth²; Madeline R. Sterling¹. ¹Weill Cornell Medical College, New York, NY; ²Johns Hopkins University, Baltimore, MD; ³NewYork Presbyterian Cornell, New York, NY. (Control ID #3185462)

BACKGROUND: Caregiver strain is associated with adverse effects on caregivers' own health, particularly if the caregiver has cardiovascular disease. Less is known about the effects of caregiving strain among those with diabetes, a disease which has high self-care demands. Using a national sample, this cross-sectional study examined the effect of caregiver strain on caregivers' diabetes self-care behaviors.

METHODS: This study was conducted using data from the REGARDS study, a national, observational, longitudinal cohort of 30,239 black and white adults aged 45 years. A baseline telephone interview that included health behaviors was followed by an in-home visit collecting physiologic data, medication adherence, and dietary information. Participants who reported having diabetes and being a caregiver were included. Caregiver strain was assessed with, *"How much of a mental or emotional strain is it to provide this care?"* Responses were categorized as no strain, some strain, or high strain. Diabetes self-care was assessed across 4 domains (diet, exercise, smoking status, and medication adherence) and a composite self-care score which summed performance across these 4 domains (low [0-3], medium [4-5], and high [6-8]). The association between caregiving strain and diabetes self-care score was examined with multi-variable logistic and ordinal regression, adjusting for demographic, clinical, physical and mental function, and caregiving covariates.

RESULTS: The sample included 795 caregivers with diabetes of mean age 63 years; 69% were women, 56% were black, and 18.4% reported

high levels of caregiver strain. Being a woman, low income, low self-reported mental and physical health, high levels of stress, lack of social support, and spending 30 hours a week caregiving were associated with high caregiver strain. For diabetes self-care behaviors, compared to those with no or some strain, high caregiver strain was associated with less physical activity ($p<0.05$), low medication adherence ($p=0.002$), and overall worse self-care with lower composite self-care scores ($p<0.02$). In unadjusted models, high caregiver strain was associated with less physical activity (OR: 0.67 [95% CI: 0.46, 0.97]), low medication adherence (OR: 0.53, [0.35, 0.82]), and less optimal self-care overall (0.57, [0.36, 0.91]). After adjustment for sociodemographic data and cholesterol, the association between high strain and lower overall self-care persisted (aOR 0.59 [0.36, 0.97].) After adjustment through all models, only the association between high strain and low medication adherence persisted (aOR: 0.52, [0.30, 0.89].)

CONCLUSIONS: These findings suggest that caregiving may interfere with caregivers' ability to take their own medications. Longitudinal studies are needed to determine the impact of this finding on health outcomes among diabetic caregivers. Additionally, increased awareness of the ramifications of caregiver strain on self-care is needed among medical providers and caregivers.

CAREMORE'S INNOVATIVE MODEL OF CARE FOR HIGH-RISK MEDICAID PATIENTS IN THE MID-SOUTH: PRELIMINARY OUTCOMES AND LESSONS LEARNED

Mary E. McBride¹; Sandeep Palakodeti²; Laura R. Spraberry¹; James E. Bailey¹. ¹University of Tennessee Health Science Center, Memphis, TN;

²CareMore Health, Memphis, TN. (Control ID #3185955)

BACKGROUND: CareMore (CM), an integrated health plan and care delivery system, is seen as an innovator in improving outcomes and patient-centered care for the Medicaid population. Their model focuses on using extensivists in hospital to clinic transitions and a care team to provide support for patients. This study documents the early impact of the model and describes strengths and weaknesses from the perspective of personnel.

METHODS: This cross-sectional mixed-methods study evaluated early experience with the CM model which uses capitated payment from one Medicaid managed care organization (MCO) to serve some Medicaid patients in Shelby Co., TN. Assignments were non-random, with purposeful assignment of high-risk patients. Claims data for March '17-April '18 were used to compare outcomes between CM and non-CM patients, stratified by eligibility (e.g. Temporary Assistance for Needy Families [TANF], Aged/Blind/Disabled Non-Dual [ABD ND], & Long-Term Supportive Services [LTSS]), age, and gender. Outcomes were: number of ED visits, hospitalizations, hospital days, and specialist visits per 1000 members per year. We employed qualitative key informant interviews to evaluate the strengths and weaknesses of the model. Interviews with staff facilitated discussion of ways CM serves patients well, achieving lower hospitalization rates, what differentiates them from other clinics, motivation for working at CM, and suggestions for improvement.

RESULTS: CM served 22.4% (N=7637) of the MCO's patients during the period. CM ED visits were lower for TANF 21-44 F (% difference [] -14.9), TANF 21-44 M (-34.5), TANF 45+ (-31.6), and ABD ND (-25.1); specialist visits were similarly lower. Hospitalizations were lower for TANF 21-44 F (-2.1), TANF 45+ (-42.4), and ABD ND (-13.6). CM had similar reductions in hospital days in these groups. Eighteen employees completed interviews. Positive themes identified include holistic approach, case management, transitions of care, relationships with patients, extensivists, and wraparound team. They identified areas in which CM performed better: holistic approach, case management, relationships with patients, and wraparound team. Employees identified areas needing improvement: wait time, transportation, walk-ins, and accessing specialists.

CONCLUSIONS: This study provides early evidence that the CM model is improving outcomes and reducing costs for Medicaid patients in Shelby Co. Despite serving sicker patients, CM generally achieved better results for TANF and ABD ND patients: less ED visits, hospitalizations, hospital days, and specialist visits, resulting in lower health care use. Other providers performed better for members ages 14-20 and for LTSS members. Staff feel they are building relationships, yielding improved outcomes and cost savings. This study suggests that the model has potential to reduce costs and improve care for Medicaid patients. Future work is needed to further assess key components of the model and its added impact on clinical outcomes.

CASCADES FOLLOWING LOW-VALUE CARE: PRE-OPERATIVE ELECTROCARDIOGRAM FOR CATARACT SURGERY

Ishani Ganguli¹; Claire Lupo¹; Alexander J. Mainor²; Stephanie Raymond²; Qianfei Wang²; E. John Orav¹; Chiang-hua Chang²; Nancy E. Morden³; Meredith Rosenthal⁴; Carrie H. Colla²; Thomas D. Sequist¹. ¹Brigham and Women's Hospital, Chestnut Hill, MA; ²The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, NH; ³The Dartmouth Institute of Health Policy and Clinical Practice, Lebanon, NH; ⁴TH Chan Harvard School of Public Health, Boston, MA. (Control ID #3183156)

BACKGROUND: Little is known about downstream health care use triggered by low-value services. Measurement of such "cascades" is essential to understanding the full impact of low-value care. We described cascades (tests, treatments, visits, hospitalizations, and new diagnoses) following a common low-value service: pre-operative electrocardiogram (EKG) for patients undergoing cataract surgery.

METHODS: We used a random 20% sample of Fee-for-Service Medicare beneficiaries age 66 years or older without known heart disease who underwent cataract surgery 2014-2015. We compared beneficiaries who received a pre-operative EKG to those who did not. Our primary outcome was cascade event rates and associated charges in the 90 days following pre-operative EKG (or in a matched timeframe for the comparison group). Among those who received a pre-operative EKG, we determined patient, physician, and area-level characteristics associated with experiencing a potential cascade.

RESULTS: Among 110,183 cataract surgery recipients, 11.3% (n=12,408) received a pre-operative EKG; of those, 14.4% (n=1,789) had at least one potential cascade event. Those who received a pre-operative EKG experienced 5.11 [95%CI, 3.96-6.25] additional events per 100 beneficiaries relative to the comparison group. This included 2.18 [95%CI, 1.34-3.02] tests, 0.33 [95%CI, 0.19-0.46] treatments, 1.40 [95%CI, 1.18-1.62] new patient cardiology visits, and 1.21 [95%CI, 0.62-1.79] new cardiac diagnoses. Payment for the additional services was \$559 per Medicare beneficiary [95%CI, \$342-\$775], or \$35 million annually, in addition to the \$3.3 million paid for the pre-operative EKGs across all Medicare beneficiaries. Among pre-operative EKG recipients, those who were older (Adjusted Odds Ratio (AOR) 1.43 for 75-84 years old vs. 66-74 years old [95%CI, 1.29-1.59]), had more chronic conditions (AOR 1.19 for each additional Elixhauser condition [95%CI, 1.15-1.23]), lived in more cardiologist-dense areas (AOR 1.06 [95%CI, 1.03-1.10]), or had their pre-operative EKG performed by a cardiac specialist (AOR 1.29 [95%CI, 1.13-1.48]) were more likely to experience a potential cascade.

CONCLUSIONS: Care cascades following pre-operative EKG for cataract surgery are infrequent but costly. We may see substantial savings from policy and practice interventions to reduce both low-

value services and the cascades that follow. Payers might incentivize beneficiaries to see clinicians with lower rates of low-value ordering while health systems might use clinical decision support or specialist e-consultations. This claims-based study is limited by clinical details that would confirm intentions behind billed services, so we used conservative estimates of cascade events relative to a comparison group. We did not capture other cascade elements such as complications from cascade procedures or psychological or financial harm to patients. Further work might explore these aspects of cascades and examine cascades following other low value events.

CASE MANAGEMENT AS A SOLUTION TO ADDRESSING HEALTH RELATED SOCIAL NEEDS: COMPETING RATIONALES AND UNINTENDED CONSEQUENCES

Elena Byhoff¹; Lauren A. Taylor². ¹Tufts Medical Center, Boston, MA; ²Harvard Business School, Boston, MA. (Control ID #3182959)

BACKGROUND: Health care systems are building capacity to address health related social needs. Community based organizations (CBOs) are strategically investing in Case Management (CM) activities to better position themselves as partners with health care systems to address health related social needs. Little is known, however, about how CBOs define CM and what consequences might be of significant investment in CM by the social service sector.

METHODS: We used mixed methods to understand how Massachusetts CBO leaders envision partnership with health care systems to address unmet social needs. We recruited executives and senior staff working in social service sectors identified as priorities by policy-makers and health care administrators. Participants completed a 15-item survey on organizational structure and scope of services, including a variety of CM services. Participants also took part in semi-structured interviews lasting 1 hour. We used a snowball sampling strategy to recruit additional participants until achieving thematic saturation. Interviews were recorded, transcribed and inductively coded to identify themes highlighting CM strategies.

RESULTS: Leadership and executive staff (n=46) from CBOs across Massachusetts represented 9 social services sectors: food, housing, community centers, legal services, transportation, workforce development, domestic violence, and early childhood education. Survey responses (response rate 87%) indicated that CM services were described as core organizational functions across nearly all participating CBOs. CM services included screening for social needs and referring to appropriate organizations, assessing eligibility for services and application assistance for services or entitlements. Qualitative data analysis suggested that CBO leadership noted several ways in which CM was seen as a high-value strategy, explaining the popularity of CM services statewide. The perceived mechanisms through which CM produced value were: (1) CM improves patient care by delivering high touch interventions for complex patients; (2) CM allows CBOs to grow their organizational footprint by increasing billable services and referral capacity; and (3) CM facilitates inter-organizational partnership to reduce overall system complexity and navigate patients more effectively to needed resources. Nevertheless, interviewees expressed explicit concern that over-investment in CM services may medicalize social service delivery and increase demand and wait-times for already limited social services. Investment in CM services by both health care and many CBOs may also create CM redundancy, thereby unintentionally overburdening patients most in need of simplified care and assistance with multiple competing CMs.

CONCLUSIONS: Without agreed upon rationales as to how CM should be provided and scaled, CM may actually add complexity and cost to the CBO ecosystem. A framework for investment in CM as a tool for brokering clinical-community linkages may be warranted.

CHALLENGES AND OPPORTUNITIES IN ENGAGING PRIMARY CARE PROVIDERS IN BRCA TESTING: EARLY RESULTS FROM THE BFOR STUDY

Lydia E. Pace¹; Nadine Tung²; Jada G. Hamilton³; Camila Gabriel⁴; Yeonsoo S. Lee¹; Sahitya Raja¹; Colby Jenkins⁴; Anthony J. Braswell⁷; Kelly Morgan³; Jeffrey Levin³; Jeremy Block³; Susan Domchek⁶; Katherine Nathanson⁶; Heather Symecko⁶; Beth Karlan⁵; Daniella Kamara⁷; Kenneth Offit³; Judy Garber⁴; Nancy L. Keating^{8, 1}. ¹Brigham and Women's Hospital, Boston, MA; ²Beth Israel Deaconess Medical Center, Boston, MA; ³Memorial Sloan Kettering Cancer Center, New York, NY; ⁴Dana-Farber Cancer Institute, Boston, MA; ⁵David Geffen School of Medicine at UCLA, Los Angeles, CA; ⁶Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; ⁷Cedars-Sinai Medical Center, Los Angeles, CA; ⁸Harvard Medical School, Boston, MA. (Control ID #3182765)

BACKGROUND: Engaging primary care providers (PCPs) in genetic testing could increase access to these services. The BRCA Founder Outreach (BFOR) study offers online education and no-cost BRCA1/2 founder mutation testing to individuals of Ashkenazi Jewish descent in 4 U.S. cities, with results review and management by participants' PCPs or genetics specialists. We sought to understand participants' interest in engaging PCPs in results disclosure, PCPs' willingness to disclose results, and PCPs' attitudes about and experience with genetic testing.

METHODS: BFOR participants were asked if they wished to receive BRCA results from their PCP or BFOR-affiliated genetics specialists; negative results with no further evaluation needed were disclosed via mail. We are surveying the first 125 invited PCPs from each city about their experiences and preferences for involvement in genetic testing and the first 100 PCPs who disclose results about their disclosure experience. We used descriptive and Chi-square statistics.

RESULTS: By December 2018, of 2497 participants enrolled, 792 (33%) requested their PCP disclose results; the others requested a BFOR genetics specialist. Of 763 invitations sent to 585 unique PCPs (some PCPs had >1 patient enrolled), PCPs agreed to disclose results 45% of the time (237 PCPs). Among 471 PCPs surveyed to date, 214 (45%) have responded. Respondents were more likely than non-respondents to agree to disclose results (59% vs. 30%, p<0.001). Most respondents (91%) had been asked by patients about BRCA testing in the past year. Overall, 76% reported feeling very or somewhat well-qualified to recommend BRCA testing, 60% felt very or somewhat well-qualified to share results, and 60% noted genetic testing was or could be easily incorporated into their practice. The most frequently identified major obstacles were genetic testing costs, lack of insurance coverage for testing, and lack of counseling experience. Most PCPs (78%) were interested in further education in BRCA risk assessment and testing. Among the 68 respondents who reported declining to share results with their patients, the most common reasons were limited knowledge and belief this should be done by a specialist. In the post-disclosure survey, of 81 PCPs who disclosed positive results or negative results requiring further evaluation, 42 (53%) have responded. Most (74%) felt very comfortable sharing results; 26% felt somewhat comfortable. Among the subset who disclosed positive results (n=5), 4 felt somewhat and 1 felt very comfortable.

CONCLUSIONS: Early BFOR results suggest challenges and opportunities for engaging PCPs in genetic testing. Only one-third of participants nominated their PCP to disclose their BRCA results, and over half of those PCPs declined. PCPs described barriers to integrating genetic testing in their practice, but most who disclosed results felt comfortable doing so. Ongoing work will examine factors associated with participants' and PCPs' preferences to guide interventions to educate and support PCPs.

CHALLENGES TO ABNORMAL MAMMOGRAM FOLLOW-UP: PERSPECTIVES FROM PRIMARY CARE PROVIDERS

Leah S. Karliner¹; Karla Kerlikowske²; Nancy Burke³; Sarita Pathak¹; Steven Gregorich¹; Jennifer Livaudais-Toman¹; Celia P. Kaplan¹. ¹University of California, San Francisco, Greenwich, CT; ²University of California San Francisco, San Francisco, CA; ³UC Merced, Merced, CA. (Control ID #3186174)

BACKGROUND: Timely follow-up of an abnormal mammogram result can help avoid a delay in breast cancer diagnosis and, in turn, a more advanced cancer. Our prior research demonstrated that facilities with longer follow-up times have the expectation that the referring provider is primarily responsible for communication of abnormal results and ensuring women undergo appropriate follow-up. We set out to understand the primary care physician (PCP) perspective on communication responsibility and abnormal mammogram follow-up.

METHODS: Survey of all PCPs in San Francisco (SF) about their experiences with communication and care coordination of abnormal mammogram results and diagnostic follow-up. We used names and emails of PCPs practicing in academic, public health, and Veterans Affairs Medical Center settings combined with searches of publicly available health plan websites to identify PCPs actively practicing in SF. PCPs completed the survey online or by mail.

RESULTS: Of 588 eligible PCPs, 300 (51%) completed the survey: 64% were general internists; 33% were in private practice, 25% public safety net, 26% academic practice, and 16% staff model HMO (Kaiser or VA). Participants graduated from medical school on average 21.9 ± 11.8 years previously. PCP patient panels had a mean of 65% (range 0-100%) minority and 33% (range 0-100%) LEP patients. Only 24% of PCPs felt they were solely responsible for notifying a woman of her abnormal mammogram result and need for follow-up, 20% felt radiology was solely responsible, and 56% felt it was a shared responsibility of the PCP with radiology. This was similar with regard to perceived responsibility for notifying a woman of her radiology-guided biopsy results (33% PCP only, 47% shared PCP & radiology; 20% radiology only). Forty-four percent reported having no formal system for tracking the need for—and completion of—diagnostic testing after an abnormal mammogram. Important barriers were cited as impacting PCPs' ability to track women for follow-up: no formal tracking system (33%), competing time demands (34%), no dedicated staff to support tracking (26%). Only 25% of PCPs felt well equipped to explain to a woman what to expect during a core biopsy; 60% reported women sometimes/very often asked questions about breast biopsy that they lacked the expertise to answer. A third (31%) of PCPs found it somewhat/very difficult to discuss abnormal mammogram or biopsy results with women who have a low education level, 23% with women from a very different cultural group from their own, and 47% with non-English speaking women.

CONCLUSIONS: Our data suggest the need for 1) standardized protocols to optimally delineate responsibilities of PCPs and radiologists, and 2) health system investment in formal tracking and dedicated staff to ensure timely, equitable care for all women after an abnormal mammogram or breast biopsy. Additionally, many PCPs would benefit from education on breast biopsy and training on communication across differences.

CHANGES IN ECONOMIC AND CLINICAL OUTCOMES UNDER CMS MANDATORY BUNDLED PAYMENTS FOR JOINT REPLACEMENTS

Derek A. Haas^{1, 2}; Xiaoran Zhang^{1, 2}; Robert S. Kaplan^{2, 1}; Zirui Song^{3, 4}. ¹Avant-garde Health, Boston, MA; ²Harvard Business School, Boston, MA; ³Harvard Medical School, Boston, MA; ⁴Massachusetts General Hospital, Boston, MA. (Control ID #3186135)

BACKGROUND: In 2016, CMS launched its first mandatory bundled payment model, the Comprehensive Care for Joint Replacement (CJR) model, through randomizing metropolitan statistical areas (MSAs) into the program.

This study evaluates changes in key economic and clinical outcomes associated with the CJR after 2 full years.

METHODS: We used a difference-in-differences model to compare Medicare spending, quality of care, utilization, and patient characteristics in episodes of lower extremity joint replacements between propensity-score matched CJR and non-CJR hospitals. The propensity score was constructed with patient and hospital characteristics. Using 100% Medicare Part A data and 5% Medicare Part B data from January, 2014 through March, 2018, we used a linear model adjusted for age, sex, risk, and hip fracture status. We used an intention-to-treat framework, in which we studied episodes in all 75 MSAs initially randomized into treatment relative to control. We also estimated the local average treatment effect among 67 MSAs that received the full CJR.

RESULTS: We identified episodes for lower extremity joint replacement beginning with 815 hospitals in MSAs that were randomly assigned to the CJR and 955 hospitals in MSAs that were randomly assigned to control. Within a joint replacement episode, Medicare Part A claims spending accounted for nearly 90% of total spending in both treatment and control. After propensity score matching, there were 157,828 primary lower extremity joint replacement episodes in the CJR group and 180,594 episodes in the control group. The CJR led to a decrease of \$582 per episode ($p<0.001$) in Medicare Part A claims spending, a 2.5% savings on claims driven by a 5.5% decline ($p<0.001$) in 90-day post-acute care spending, concentrated in skilled nursing facilities and inpatient rehabilitation facilities. No significant changes in hospital length of stay, readmissions, complications, 30-day or 90-day mortality, volume of episodes, or patient characteristics were found.

CONCLUSIONS: The CJR was associated with reduced Medicare Part A claims spending over 2 years, largely through lower post-acute spending, without detectable changes in the volume of inpatient admissions for primary hip and knee replacements, length of stay, complication rates of hip and knee replacements, 90-day readmissions, mortality out to 90 days, or characteristics of beneficiaries in whom the bundled payment was triggered. Lower episode spending was driven by a decrease in 90-day post-acute care spending, concentrated within skilled nursing facilities and inpatient rehabilitation facilities. Estimated savings on claims, while consistent with changes in provider behavior, may not have exceeded the reconciliation payments to hospitals reported by CMS to date. The CJR model is the first wide-scale mandatory bundled payment model implemented by CMS in a randomized fashion. Mandatory bundled payments may serve as a useful model for policy efforts to slow spending without harming quality.

CHANGES IN ENROLLEES' HEALTH STATUS AFTER MEDIC-AID EXPANSION

Susan D. Goold^{2, 1}; Renuka Tipimeni^{2, 1}; Edith C. Kieffer^{1, 1}; Tammy Chang^{1, 1}; Matthias Kirch¹; Corey Bryant²; Erica Solway¹; Sunghee Lee¹; Zachary Rowe^{4, 5}; Erin Beathard¹; Sarah J. Clark^{1, 1}; Jennifer Skillicorn^{1, 1}; John Z. Ayanian^{1, 2}; Jeffrey T. Kullgren^{3, 1}. ¹University of Michigan, Ann Arbor, MI; ²University of Michigan, Keego Harbor, MI; ³Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; ⁴Friends of Parkside, Detroit, MI; ⁵Urban Research Center, Detroit, MI. (Control ID #3177579)

BACKGROUND: Evidence about the impact of Medicaid expansion on health has been mixed, and has largely come from comparing expansion to non-expansion states. We assessed the impact of Michigan's Medicaid expansion, the Healthy Michigan Plan (HMP), on the health of enrollees over time.

METHODS: From January-November 2016, the *Healthy Michigan Voices* telephone survey was conducted in English, Arabic and Spanish with 4,090 HMP beneficiaries aged 19-64 with 12 months of HMP coverage and 10 months in a Medicaid health plan (RR 53.7%). Sampling was stratified by income and region. Respondents in 2016 who consented to be re-contacted (96.4%) were eligible for the 2017 HMV Follow-Up Survey, conducted from March 2017 to January 2018 (RR 83.4%). Surveys measured demographics, health status, access to and use of health care, health risks and behaviors.

Analysis included weights for sampling probability and nonresponse. Comparisons between 2016 and 2017 included only those who responded to both surveys.

RESULTS: Of 2017 HMV follow-up survey respondents (n=3,104), 76.8% were still enrolled in HMP ("current enrollees") and 23.2% were no longer enrolled at the time of the 2017 survey. Most enrollees reported that, in the past year, their physical health had improved (29.6%) or stayed the same (56.1%), their mental health had improved (28.4%) or stayed the same (58.6%), and their oral health had improved (21.0%) or stayed the same (60.7%). Over one-third (36.4%) reported in 2017 that their health was excellent or very good. The proportion of all enrollees who reported fair or poor health decreased from 30.7% in 2016 to 27.0% in 2017 (aOR=0.66, p<.001). The largest decreases in reports of fair/ poor health from 2016 to 2017 were observed in enrollees who were Hispanic (from 28.3% to 21.5%), non-Hispanic Black (from 31.5% to 26%), from the Detroit Metro area (from 30.7% to 24.9%), and with an income 0-35% FPL (from 37.6% to 32.3%). The mean number of days of poor physical health in the past month decreased from 2016 to 2017 from 6.9 to 5.7 (Coeff=-1.32, p<.001). Fewer days of poor physical health were found in both current enrollees (from 7.0 to 5.6) and former enrollees (from 6.8 to 5.8), those with a chronic condition (from 8.2 to 6.8), those with two or more chronic conditions (from 9.9 to 8.5), those with a mental health condition (from 9.5 to 8.0), and those with a substance use disorder (from 10.0 to 8.1). There was no statistically significant decrease from 2016 to 2017 in the number of days of poor mental health or the number of days of usual activities missed due to poor physical/mental health.

CONCLUSIONS: Medicaid expansion in Michigan was associated with improvements in self-reported health and days of poor physical health, including for enrollees with chronic physical and mental health conditions.

CHANGES IN HEALTH INSURANCE COVERAGE BY OCCUPATION AFTER THE AFFORDABLE CARE ACT

Sumit Agarwal¹; Anna Goldman²; Benjamin D. Sommers³. ¹Brigham and Women's Hospital, Somerville, MA; ²Cambridge Health Alliance, Cambridge, MA; ³Harvard School of Public Health, Brookline, MA. (Control ID #3185500)

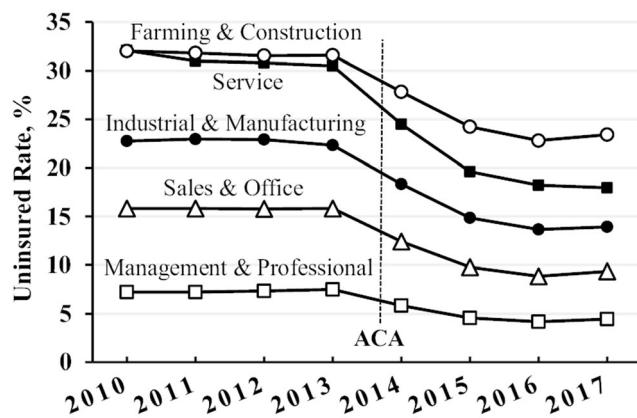

BACKGROUND: We sought to assess changes in health insurance coverage across occupations after implementation of the Affordable Care Act (ACA).

METHODS: Using data from the American Community Survey from 2010 through 2017, we examined changes in presence and type of insurance coverage before and after the ACA. We focused on five standard occupation groups: managers and professionals (e.g. chief executives, physicians), service workers (e.g. food servers, barbers), sales and office workers (e.g. cashiers, secretaries), farming and construction workers (e.g. farmers, plumbers), and industrial and manufacturing workers (e.g. machinists, truck drivers). We used a linear regression model to estimate unadjusted and adjusted changes in the following categories of coverage: uninsured, Medicaid, employer-sponsored insurance (ESI), and directly purchased insurance (includes ACA Marketplaces).

RESULTS: Uninsured rates before the ACA and coverage gains since 2014 varied significantly by occupation (Figure). Managers and professionals were the most likely to receive coverage through their employer (82.7% prior to the ACA). Those in farming and construction (56.4%) and in service (52.0%) were the least likely to receive coverage through their employer. There were modest gains in ESI among all groups, ranging from 1.9 to 3.1 percentage points. The bulk of the gains in coverage after 2014 were due to increases in Medicaid and directly purchased insurance. Service workers experienced a 4.3 percentage-point increase in directly purchased insurance and 5.8 percentage-point increase in Medicaid. There were also large gains for those in sales and office

(2.8 percentage points and 3.2 percentage points), farming and construction (2.8 percentage points and 3.0 percentage points), and industrial and manufacturing (2.8 percentage points and 3.3 percentage points). There were smaller gains for managers and professionals (0.8 percentage points and 1.3 percentage points). All p-values were <0.001.

CONCLUSIONS: The largest gains in coverage associated with the ACA occurred among non-professional workers, and these positive effects on coverage were not due to crowd-out of ESI. Policies that reduce public insurance enrollment or disrupt the ACA's health insurance Marketplaces will have adverse effects on those who have less access to employer-sponsored insurance.

CHANGES IN HOSPITAL ACQUIRED CONDITIONS AND MORTALITY ASSOCIATED WITH THE HOSPITAL ACQUIRED CONDITION REDUCTION PROGRAM

Emily Arntson^{1, 2}; Justin B. Dimick^{2, 3}; Usha Nuliyalu³; Joshua Errickson³; Tedi A. Engler¹; Andrew Ryan^{1, 3}. ¹University of Michigan School of Public Health, Ann Arbor, MI; ²University of Michigan Medical School, Ann Arbor, MI; ³University of Michigan, Ann Arbor, MI. (Control ID #3184751)

BACKGROUND: Hospital acquired conditions (HACs) are common, costly, and deadly. Despite recent reductions, HACs still occur at a rate of 121 events per 1,000 discharges. Building on previous payment reforms to reduce HACs, CMS announced the Hospital Acquired Condition Reduction Program (HACRP) in August 2013. The program - largely focused on surgical admissions - reduces Medicare payments by 1% for hospitals in the worst performance quartile of targeted hospital-acquired conditions. Penalty criteria are based on absolute performance levels for a relatively narrow set of measures. However, rates of HACs are highly sensitive to hospital coding practices. As a result, the HACRP's effect on both targeted and downstream clinical outcomes is uncertain.

METHODS: Using an interrupted time series design, we estimated models with linear splines to test for changes in hospital-acquired conditions and 30-day mortality before the Affordable Care Act (ACA), after the ACA, and after the HACRP. To assess whether improvements may be related to coding practices, we examined changes in the percentage of hospital-acquired conditions that were coded as present-on-admission. We used data from the 100% MedPAR Files for Medicare patients undergoing surgery and discharged from eligible hospitals between January 1, 2009 and August 31, 2015 (n = 8,857,877).

RESULTS: Patients experienced hospital-acquired conditions at a rate of 13.39 per 1,000 discharges (95% confidence interval {CI}, 13.1 to 13.68) in the pre-ACA period. This rate declined after the

ACA was passed and declined further after the HACRP was announced (adjusted difference in annual slope, 1.34 [95% CI, -1.64 to -1.04]). Adjusted 30-day mortality was 3.69 (95% CI, 3.64 to 3.74) in the pre-ACA period among patients receiving surgery. 30-day mortality declined after the ACA (adjusted annual slope -0.04 [95% CI, -0.05 to -0.02]) but was flat after the HACRP (adjusted annual slope -0.01 [95% CI, -0.04 to 0.02]). While the use of coding for present-on-admission slightly increased after the HACRP was announced, coding changes did not explain reductions in hospital-acquired conditions.

CONCLUSIONS: Overall, hospital-acquired conditions targeted under the HACRP declined at a greater rate after the program was announced. The HACRP was not associated with declines in 30-day mortality. This suggests that either: 1) hospitals are artificially reducing reported HAC rates and not improving downstream clinical outcomes, such as mortality, or 2) hospital-acquired conditions are not sufficiently common or mechanistically related to major harm such that improvement will drive a mortality reduction. Further investigation, especially into hospitals' HAC reduction mechanisms, is needed. Our findings are instructive to policymakers seeking to improve patient safety. CMS should continue to invest in robust systems to capture valid HAC measures and externally audit these data in order to ensure their integrity for value-based payment programs.

CHANGES IN PERCEPTIONS OF DISCRIMINATION IN HEALTHCARE: AN ANALYSIS OF THE CALIFORNIA HEALTH INTERVIEW SURVEY 2003-2017

Lucy Schulson¹; Ziming Xuan³; Michael K. Paasche-Orlow²; Alicia Fernandez⁴. ¹Boston University/ Boston Medical Center, Boston, MA; ²Boston University, Boston, MA; ³Boston University School of Public Health, Boston, MA; ⁴University of California San Francisco, San Francisco, CA. (Control ID #3185334)

BACKGROUND: Research in the early 2000s in California demonstrated that racial and ethnic minorities, immigrants, and those with limited English proficiency (LEP) experienced high rates of discrimination in healthcare. Less is known how patients' perceptions of discrimination in healthcare have changed for these groups.

METHODS: We used data from the 2003, 2005, 2015, 2016, and 2017 waves of the California Health Interview Survey (CHIS) to determine if rates of perceived discrimination in healthcare have changed. We identified those as having experienced discrimination if they responded "yes" to the question, "Was there ever a time when you would have gotten better medical care if you had belonged to a different race or ethnic group?" and reported this occurred within the last five years. Our primary exposure of interest was survey year dichotomized as combined 2003 and 2005 and combined 2015, 2016, and 2017. We used jack-knife replicate weights provided by CHIS and performed chi-square analyses comparing perceptions of discrimination in 2003-2005 vs. 2015-2017 and multivariate logistic regression comparing discrimination in late vs. early years controlling for race, poverty level, education, insurance status, usual source of care, self-reported health, and LEP. We also performed sub-analyses by racial/ethnic groups, immigrant status, and LEP status.

RESULTS: There were 84,088 participants in 2003-2005 with 5.97% of the population reporting recent discrimination in healthcare and 63,242 participants in 2015-2017 with 3.98 % of the population reporting recent discrimination in healthcare (p<.0001). Latinos and Asians experienced less discrimination in healthcare in 2015-2017 vs. 2003-2005 (6.58% vs. 12.73% p<.0001; 4.74% vs. 7.37% p=.00770). Rates were stable among whites and African-Americans (2.26% vs. 2.61% p=0.25; 13.84% vs. 13.14% p=0.75). Fewer immigrants and LEP individuals reported discrimination in healthcare

in 2015-2017 vs. 2003-2005 (6.16% vs. 12.10% $p<.0001$; 7.69% vs. 15.84% $p<.0001$). In adjusted analyses, perceptions of discrimination in healthcare decreased in 2015-2017 compared to 2003-2005 (OR 0.608, CI 0.519, 0.712, $p <.0001$). There was a significant race by year interaction for Latinos (OR 0.584, CI 0.422, 0.809, $p=.0012$), but not for Asians or African-Americans (OR 0.767, CI 0.456, 1.289, $p=0.664$; OR 1.11, CI 0.69, 1.794, $p=0.664$). There was a significant immigrant by year interaction and LEP status by year interaction (OR 0.594, CI 0.440, 0.801, $p=.0007$; OR 0.671, CI 0.499, 0.902, $p=.0083$).

CONCLUSIONS: Perceptions of discrimination in healthcare in California decreased between 2003- 2005 and 2015-2017 but only for Latinos, immigrants, and LEP individuals. African Americans reported consistently high rates of discrimination. Interventions specifically targeted at reducing discrimination are still necessary.

CHANGES IN THE COLORECTAL CANCER INCIDENCE AND MORTALITY IN NEW YORK CITY IN THE CONTEXT OF INCREASED SCREENING, 2003-2015

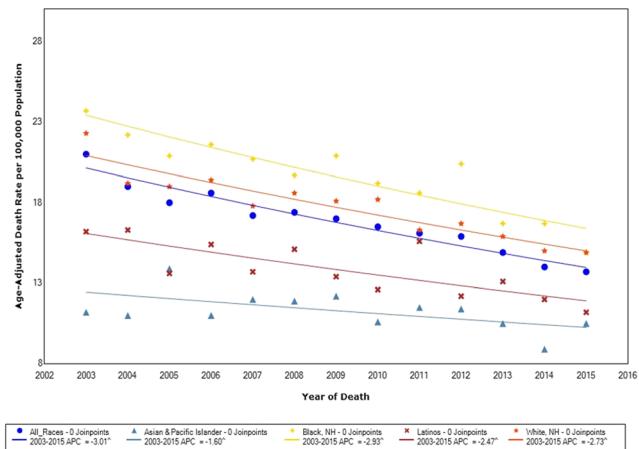

Jennifer J. Brown³; Charles Asumeng³; David Greenwald², Matthew A. Weissman^{1, 2}; Ann Zauber⁴; Jared Striplin³; Justin M. List⁵; Shannon M. Farley³; Sidney Winawer⁴. ¹Mount Sinai Beth Israel, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³New York City Department of Health and Mental Hygiene, New York, NY; ⁴Memorial Sloan Kettering Cancer Center, New York, NY; ⁵New York City Health + Hospitals, New York, NY. (Control ID #3179909)

BACKGROUND: Incidence rates for new colorectal cancer (CRC) cases have been falling 2.6% each year over the last 10 years, while mortality rates have been falling 2.4% each year over 2006-2015, nationally. CRC screening has increased nationally during this time. The New York Citywide Colon Cancer Control Coalition (C5) in partnership with the New York City (NYC) Department of Health and Mental Hygiene promoted CRC screening from 2003 to present. Here, we report rates of change and trends in CRC incidence and mortality in the context of changes in colonoscopy screening rates from 2003 to 2015 in NYC.

METHODS: Age-adjusted CRC incidence and mortality rates were calculated using the New York State Cancer Registry and NYC Vital Statistics Data. Screening rates for CRC by colonoscopy were estimated using the NYC Community Health Survey. We used the Joinpoint Regression Program to determine annual percent change (APC) for incidence and mortality and screening curves.

RESULTS: There was a 29% decrease in age-adjusted CRC incidence from 54.1 to 38.4/100,000 and a 35% decrease in the CRC mortality rate from 21.0 to 13.7/100,000, from 2003 to 2015, Figure 1. In 2015 Blacks had higher CRC mortality rates (14.9/100,000), compared to Hispanics (11.2/100,000) and Asians (10.5/100,000). In 2015 CRC mortality rates were more than twice as high in Central Harlem and the South Bronx neighborhoods compared to Chelsea and Union Square. Asian/Pacific Islanders had significantly lower CRC screening, at 58.8% compared to Blacks (63.9%), Hispanics (64.3%) and Whites (64.7%). Overall, screening rates increased from 41.7% to 69.9% from 2003 to 2015. Using single point estimates, CRC screening increased at APC = 15.65, from 2005 to 2009 APC = 3.69, and from 2009 to 2015 APC = 0.80.

CONCLUSIONS: A decreasing burden of CRC was evident from lower incidence and mortality rates from 2003 to 2015. During this time screening colonoscopy rates in NYC increased after a citywide public health effort. While these inverse trends are going in the right direction, the persistent disparities for certain NYC neighborhoods and racial/ethnic groups demonstrate a need for continued targeted public health efforts in CRC prevention.

CRC Mortality Rate per 100,000 NYC Population, 2003 to 2015, Age-Adjusted: NYC Vital Statistics Data

CHANGES IN VETERANS' COVERAGE AND ACCESS TO CARE FOLLOWING THE AFFORDABLE CARE ACT

Alan T. Kelley^{1, 2}; Renuka Tipirneni¹; Helen Levy¹. ¹University of Michigan, Ann Arbor, MI; ²VA Ann Arbor Health System, Ann Arbor, MI. (Control ID #3172950)

BACKGROUND: Insurance coverage for nonelderly veterans improved following coverage expansions of the Affordable Care Act (ACA). However, whether improvements in coverage have translated into improved access to healthcare has not been previously reported.

METHODS: Using data from the Behavioral Risk Factor and Surveillance System, self-reported insurance status and access to care among nonelderly veterans ages 18-64 were compared in the three-year periods before and after ACA coverage expansions went into effect. Measures of self-reported insurance status, general access to care (cost-related delays in receiving care), and access to primary care (report of having a usual source of care and report of having a checkup in the last 12 months) were included. Difference-in-differences analysis was used to compare changes in Medicaid expansion states to non-expansion states between the time periods. Pre-specified subgroup analyses were performed for veterans with low socioeconomic status (SES) and fair to poor health (poor health).

RESULTS: Among all nonelderly veterans, uninsurance decreased 4.4 percentage points (12.6% to 8.2%, $P<0.05$), and cost-related delays in care declined 1.9 percentage points (11.9% to 10.0%, $P<0.05$). Report of no checkup within 12 months declined slightly (28.1% to 26.7%, $P<0.05$) but there was no significant change in report of a usual source of care. Compared to all nonelderly veterans, veterans with low SES or poor health had greater declines in uninsurance and cost-related delays in care; however, differences in report of no checkup within 12 months or usual source of care were non-significant. When comparing Medicaid expansion states to non-expansion states, differences in uninsurance rates were negligible (<1%) and differences in all access measures were mixed and mostly non-significant.

CONCLUSIONS: Uninsurance and cost-related delays in care decreased, especially among nonelderly veterans with low SES and poor health. However, changes in primary care access were mixed. Additional study is needed to understand why gains in coverage among veterans did not translate into larger gains in access.

CHARACTERISTICS AND INJURY MECHANISMS OF VETERAN PRIMARY CARE SUICIDE DECEDENTS WITH AND WITHOUT DIAGNOSED MENTAL ILLNESS; 2000-2014

Joseph A. Simonetti^{1, 2}; Rebecca I. Piegari³; Charles Maynard⁴; Lisa Brenner^{1, 6}; Alaina M. Mori⁴; Edward P. Post^{7, 8}; Karin M. Nelson^{4, 9}; Ranak Trivedi^{5, 10}. ¹Veterans Health Administration, Denver, CO; ²University of Colorado School of Medicine, Aurora, CO; ³Department of Veterans Affairs, Canandaigua, NY; ⁴VA Puget Sound Healthcare System, Seattle, WA; ⁵Center for Innovation to Implementation, Palo Alto, CA; ⁶University of Colorado, Aurora, CO; ⁷VA HSRD, Ann Arbor, MI; ⁸University of Michigan Medical School, Ann Arbor, MI; ⁹University of Washington, Seattle, WA; ¹⁰Stanford University, Palo Alto, CA. (Control ID #3184627)

BACKGROUND: Suicide is the 10th leading cause of death in the United States, and rates increased among most groups from 1999-2014. Suicide prevention programs largely focus on identifying and treating mental health diagnoses (e.g., depression) because they are well-known, prevalent, and potent predictors of suicide. However, no study has assessed what proportion of suicide decedents lacked such diagnoses within a primary care population.

METHODS: We conducted a retrospective cohort study of Veterans Health Administration (VHA) primary care patients who died by suicide from 2000-2014. We identified Veterans receiving primary care using data from the VHA Corporate Data Warehouse (CDW). These records were then linked to the US Department of Veterans Affairs and Department of Defense Joint Suicide Data Repository to identify those who died by suicide (ICD-10 codes: X60-X84, Y87.0) and their mechanism of suicide (e.g., firearm injury). Using ICD-9 codes available in the CDW, we categorized suicide decedents by whether they had a history (yes/no) of any of the following mental health diagnoses: depression, post-traumatic stress disorder, anxiety disorder, substance use disorder, schizophrenia or bipolar disorder. CDW data were also used to characterize decedents' sociodemographic and clinical characteristics, including total physical health diagnoses and healthcare utilization. We compared differences between those with and without any mental health diagnosis using chi-square or Student's T-tests.

RESULTS: Of the 9,550,726 veterans identified, 28,812 (1.1%) died by suicide. Of those, 12,740 (44.2%) had no history of a mental health diagnosis. In comparison to those with mental health diagnoses, decedents with no mental health diagnoses were more likely to be older (68 vs. 57 years, p<0.01), male (98.2% vs. 95.4%, p<0.01), and married or partnered (49.4% vs. 35.9%, p<0.01), were less likely to have a service-connected disability (57.4% vs. 72.8%, p<0.01), and had a higher number of physical health diagnoses (2.63 vs. 2.59, p<0.01). In the year prior to death, decedents without mental health diagnoses had fewer primary care visits, mental health visits, emergency department visits, and hospitalizations. Those without mental health diagnoses were more likely to die by firearm injury (78.8% vs. 59.9%, p<0.01).

CONCLUSIONS: From 2000-2014, nearly half of VHA primary care patients who died by suicide did not have an antemortem mental health or substance-related diagnosis. Veterans without mental health diagnoses who died by suicide were more likely to be older, married, male, without service-related disability benefits, and had a high number of physical health diagnoses and were more likely to die by firearm injury. Suicide prevention efforts within primary care relying solely on the identification of mental health or substance-related diagnoses may be insufficient in preventing a large proportion of veteran suicides.

CHARACTERISTICS AND QUALITY OF ROTATION-SPECIFIC RESIDENT LEARNING GOALS: A PROSPECTIVE STUDY

Adam P. Sawatsky; Andrew J. Halvorsen; Paul Daniels; Sara Bonnes; Meltiady Issa; John T. Ratelle; Christopher Stephenson; Thomas J. Beckman. Mayo Clinic, Rochester, MN. (Control ID #3175489)

BACKGROUND: Identifying learning goals is part of self-directed learning, and is triggered by the revelation of gaps in knowledge. While learning goals are part of self-directed learning, residents struggle with setting learning goals. Faculty can support self-directed learning through supporting resident learning goal development. We sought to characterize the topics and quality of residents' learning goals.

METHODS: We conducted a prospective mixed-methods study of 153 internal medicine residents, assessing 455 learning goals for general medicine inpatient rotations during the 2016-2017 academic year. For each learning goal, we coded themes, competencies and learning domains, and categorized themes into topic categories. We assessed quality using the Learning Goal Scoring Rubric (LGSR), an instrument with evidence of validity for content, internal structure and relationship to other variables. It has 4 items (specific goal, important goal, realistic multisource plan, and measurable outcome), each scored from 0-3, with a total possible score of 12. We compared learning goal topic categories, competencies, learning domains, and quality between first and second months of postgraduate (PGY) 1 residents and between PGY-1 and PGY-3 residents. For PGY-1 residents, we compared mean overall and item scores between month 1 and 2 using a paired t-test. To compare PGY-1 and PGY-3 mean overall and item scores, we used an independent 2-sample t-test. We assessed factors associated with learning goal completion and coded themes regarding barriers and facilitators to learning goal completion.

RESULTS: The overall response rate was 80%. The top three learning goal categories were patient management, specific diseases related to general medicine, and teaching skills. There were no significant changes in learning goal characteristics between PGY-1 months (p 0.04). There were differences between PGY-1 and PGY-3 residents' learning goals in patient management (28% vs 6%; p<.001), specific disease conditions (19% vs 3%; p<.001), and teaching skills (2% vs 56%; p<.001). There was no difference in the LGSR score between PGY-1 months (1.63 vs. 1.67; p=0.82). The PGY-3 learning goals were of higher quality than PGY-1 learning goals for the "specific goal" item (1.38 vs. 0.98, p=0.005), but not for other items or overall (all p 0.02). Residents reported 85% (297/347) learning goal completion, with main drivers being experience (88, 28%), intentional effort (128, 41%), and external guidance (98, 31%).

CONCLUSIONS: Residents identified a broad array of topics for learning goals. While PGY-1 residents developed learning goals in medical knowledge and patient care, PGY-3 residents developed learning goals for more integrative abilities like team management and teaching skills. Residents' learning goal quality was low, reflecting the need for more guidance from faculty members and residency programs to support residents' self-directed learning.

CHARACTERISTICS OF CANCER SURVIVORS IN OUTPATIENT SAFETY NET CLINICS

Megan Hoopes¹; Teresa Schmidt¹; Nathalie Huguet²; Kerri Winters-Stone²; Heather Angier²; Miguel Marino²; Jackilen Shannon²; Jennifer DeVoe². ¹OCHIN, Portland, OR; ²Oregon Health & Science University, Portland, OR. (Control ID #3179117)

BACKGROUND: Little is known about the prevalence of cancer survivors seen in primary care settings. To provide comprehensive healthcare and care coordination, it is important for primary care providers to understand the utilization patterns, clinical complexity, and specific needs of this growing population.

METHODS: This retrospective, observational study used electronic health record (EHR) data from 586 safety net clinics, namely community health centers (CHCs), in 20 states, from 2014-2016. CHCs serve a patient population that is largely publicly insured or uninsured, and underrepresented in research. Cancer survivors were defined as adults with a visit to a CHC and a history of malignant cancer; we identified and matched these patients in a 1:3 ratio to patients without a cancer history. We characterized cancer history (primary site, age at diagnosis, time since diagnosis) and compared survivors to their matched counterparts without a cancer history on demographic characteristics, medical complexity, and healthcare utilization. Generalized estimating equation models were used to compute adjusted odds ratios and 95% confidence intervals for select utilization indicators.

RESULTS: We identified 45,779 cancer survivors from a population of 1.2 million adult CHC patients (prevalence=3.4%). Most cancer survivors were female (60.8%), with a median age of 61. The leading cancer sites were breast (28.7% of female survivors), prostate (22.9% of males), cervical (8.8% of females), colorectal (7.1% of both sexes), melanoma (5.8%), non-Hodgkin lymphoma (4.3%), and lung and bronchus (4.1%); sex-stratified rankings agreed with national statistics. The median age at diagnosis was 58 (mean=56.9, SD=14.5). Compared to matched patients without a cancer history, survivors had been established with their clinic longer (mean=3.6 years vs. 3.0), had more CHC visits per year (mean=10.8 vs. 7.8), were more likely to be assigned a primary care provider (86.6% vs. 83.2%), and were less likely to be uninsured (13.6% vs 21.6%, p<.001 for all). Cancer survivors had much higher medical complexity, including substantially higher rates of hypertension, depression, chronic obstructive pulmonary disease, diabetes, and drug/alcohol abuse disorder diagnoses (p<.001 for all). In covariate-adjusted analyses, cancer survivors had 18% higher odds of having any opioid prescribed and 22% higher odds of chronic opioid therapy, relative to matched cancer-free counterparts (p<.001 for both).

CONCLUSIONS: Cancer history is an important health factor in primary care, as it impacts screening and follow-up recommendations. We found clear differences between CHC patients with a history of cancer and those without. Recognizing and improving the identification of cancer survivors in outpatient EHRs may improve care coordination and appropriate follow-up care.

CHARACTERISTICS OF PATIENTS WITH DUAL DIAGNOSIS OF SARCOIDOSIS AND RHEUMATOID ARTHRITIS IN COMPARISON TO ISOLATED SARCOIDOSIS OR RHEUMATOID ARTHRITIS.

Lisa Zickuhr²; Ruhani Desai¹; Rula Hajj-Ali³; Ryan Incledon³; Jean Schils³. ¹Cleveland Clinic Foundation, Cleveland, OH; ²Washington University, St. Louis, MO; ³Cleveland Clinic Foundation, Cleveland, OH. (Control ID #3159949)

BACKGROUND: Sarcoidosis and Rheumatoid Arthritis (RA) uncommonly coexist. We propose to understand the features unique to patients with dual diagnosis in comparison to those with isolated sarcoidosis or RA.

METHODS: We retrospectively searched the electronic medical record at Cleveland Clinic from 2004-2017 for ICD9 and ICD10 codes pertaining to sarcoidosis and RA. Patients were included in our analysis if they had a biopsy-proven diagnosis of sarcoidosis

and/or met the 2010 American College of Rheumatology/European League Against Rheumatism criteria for RA. Patients prescribed tumor necrosis factor inhibitors (TNFi) were excluded, as TNFi can cause a granulomatous reaction and induce sarcoidosis. Age-matched controls with sarcoidosis or RA were selected randomly via retrospective chart review in a 1:1:1 ratio. Demographic, clinical, and radiographic information were collected and compared among the three groups using ANOVA, Kruskal-Wallis, Pearson's chi-square, and Fisher's exact tests.

RESULTS: 15 patients met the criteria for the dual diagnosis of sarcoidosis and RA. Patients with dual diagnosis and isolated RA were predominantly female, while patients with isolated sarcoidosis were predominantly male. Those with dual diagnosis presented with lower pulmonary stages compared to isolated sarcoidosis cases, and their Sharp scores were lower than isolated RA patients. Despite this, patients with dual diagnosis had more frequent anti-cyclic citrullinated peptide (anti-CCP) serologies than isolated RA cases.

CONCLUSIONS: We identified 15 patients carrying both diagnoses, the largest cohort described to date. Those with dual diagnosis were demographically most similar to isolated RA cases, yet they had less joint damage as demonstrated with lower Sharp scores despite more frequent anti-CCP positivity. They also presented with lower pulmonary stages based on the Siltzbach Classification System compared to patients with isolated sarcoidosis. These findings suggest that anti-CCP antibodies may play a role in the pathogenesis of overlapping sarcoidosis and RA. They also suggest that dual diagnosis may protect against severe joint and lung manifestations of the diseases. However, this retrospective study does not account for prior use of disease modifying agents, which may account for the lower disease activity in patients with both diagnoses.

CHARACTERISTICS OF PATIENTS WHO RECEIVE OPIOIDS DURING AN ACUTE MEDICAL HOSPITALIZATION

Kaitlin Keenan²; Michael B. Rothberg¹; Simon W. Lam¹; Shoshana J. Herzig³; Vicente J. Velez¹; Kathryn A. Martinez¹.

¹Cleveland Clinic, Cleveland, OH; ²Cleveland Clinic Lerner College of Medicine, Cleveland, OH; ³Beth Israel Deaconess Medical Center, Brookline, MA. (Control ID #3184213)

BACKGROUND: Patients often report pain during medical hospitalizations, yet few guidelines exist regarding recommended use of opioids. Nearly half of medical inpatients receive opioids, however little is known about who receives them. The objective of this study was to identify characteristics associated with opioid receipt during an acute medical hospitalization.

METHODS: This is a retrospective observational study of patients at Cleveland Clinic Hospitals in 2016. The sample included patients with an acute medical hospitalization between 2-30 days who reported pain and excluded ICU stays and pre- or post-operative hospitalizations. For patients with multiple hospitalizations in 2016, one admission was randomly selected. All data came from the electronic health record. Prior opioid use was defined as any opioid prescription in the 30 days before hospitalization. Opioid receipt was defined as any opioid prescription during the hospitalization and analyzed dichotomously. Patient characteristics included age, gender, race, and smoking status. Clinical characteristics included maximum pain score during hospitalization, history of chronic pain or psychiatric diagnosis, length of stay and prior opioid use. Differences in the odds of opioid receipt were assessed using mixed effects logistic regression, accounting for clustering by discharging physician. The model was then stratified by prior opioid receipt.

RESULTS: The sample included 15,201 patients; 56% female, 70% white and mean age was 70 years (Standard Deviation (SD):16); 54% had a history of chronic pain, 38% had a history of a psychiatric diagnosis, and 16% had prior opioid use. The average maximum pain score was 6.3 (SD=3.7). Overall, 66% of patients received opioids during their hospitalization. In the overall mixed effects model, opioid receipt was associated with male gender (OR: 1.16, 95% CI: [1.08 - 1.25]), maximum pain score (OR per point: 1.31, CI: [1.29 - 1.33]), history of chronic pain (OR: 1.45, CI: [1.25 - 1.68]), and prior opioid use (OR: 1.84, CI: [1.58 - 2.14]). Black patients were less likely to receive opioids than whites (OR: 0.67, CI: [0.59 - 0.77]) and patients 65 years and over were less likely to receive opioids than those under 50 years (OR: 0.76, CI: [0.66 - 0.86]). Patients with a history of a psychiatric diagnosis were less likely to receive opioids than without (OR: 0.78, CI: [0.72 - 0.84]). In the model stratified by prior opioid use, there was no difference by race in the odds of opioid receipt for those with prior use, but among those without prior use, black patients were less likely to receive opioids than whites (OR:0.55, CI: [0.49 - 0.63]).

CONCLUSIONS: Receipt of opioids during an acute medical hospitalization varies by clinical and patient characteristics, including race and gender. Guidelines to support evidence-based opioid prescribing during medical hospitalizations are needed to promote appropriate pain management for all patients.

CHARACTERISTICS OF PHYSICIAN PRACTICES AND HOSPITALS IN MEDICARE'S NEW VOLUNTARY BUNDLED PAYMENT PROGRAM

Joshua M. Liao^{3, 1}; Joseph R. Martinez^{1, 1}; Eric Z. Shan¹; Jack Huang¹; Claire T. Dinh¹; Qian Huang¹; Amol S. Navathe^{1, 2}. ¹University of Pennsylvania, Philadelphia, PA; ²CMC VA Medical Center, Philadelphia, PA; ³University of Washington, Seattle, WA. (Control ID #3179531)

BACKGROUND: Medicare reinforced its commitment to voluntary bundled payments via the new Bundled Payments for Care Improvement (BPCI)-Advanced program. Since launching in October 2018, BPCI-Advanced has enrolled 1,547 hospital and physician group practice (PGP) participants, making it the largest voluntary bundled payment program to date. Therefore, it is important for policymakers and health care organizations to understand characteristics of BPCI-Advanced participants, particularly those "newly" attracted to bundled payments (i.e. those that did not previously participate in BPCI). Given little existing information about physician practices in bundled payments, such insight is particularly important for the PGPs that comprise nearly half of all BPCI-Advanced participants.

METHODS: We used Medicare data to identify PGPs and hospitals that participated in BPCI Model 2 or BPCI-Advanced as of October 1, 2018. We categorized participants as those continuing participation from BPCI into BPCI-Advanced ("continuing") and those newly participating in bundled payments via BPCI-Advanced ("new"). We evaluated the distribution of 557 (408 new, 149 continuing) BPCI-Advanced PGPs and 832 (662 new, 170 continuing) BPCI-Advanced Hospitals across markets nationwide, defining "new markets" as those with new, but no continuing or BPCI only, participants. Data from Physician Compare, Hospital Compare, and the American Hospital Association were used to compare characteristics of PGPs and hospitals, respectively, by continuing versus new participation status. Categorical variables were compared using Chi squared tests and continuous variables were compared using *t* tests, Kruskal-Wallis, and Wilcoxon rank sum tests. Statistical tests were 2-tailed and significant at an =0.05.

RESULTS: There was geographic variation in participation, with BPCI-Advanced engaging 66 new markets. Most were located in central rather than coastal US regions. New and continuing PGP participants differed with respect to several characteristics. New groups were less likely to be multispecialty (96.9% versus 99.9%), hospital-affiliated (91.2% versus 97.3%), and urban (96.4% versus 98.1%) ($p<0.001$ for all). New PGPs also employed different and more diversely represented specialty types than continuing groups. Among BPCI-Advanced hospitals, new participants were smaller (mean hospital beds 276 versus 341, $p=0.001$), lower volume (mean annual Medicare admissions 4,740 versus 6,861, $p<0.001$), and less likely to be not-for-profit (62.1% versus 71.6%, $p=0.04$) and teaching (58.7% versus 76.9%, $p<0.001$) (Table). New and continuing hospitals did not vary with respect to safety-net status, financial measures, or readmission rates.

CONCLUSIONS: Differences between new and continuing PGP and hospital participants suggests that BPCI-Advanced at least in part prompted some new organization types to engage in Medicare bundled payments rather than only attracting "more of the same".

CHARACTERISTICS OF USE OF SELF-MONITORING OF BLOOD GLUCOSE IN PATIENTS WITH NON-INSULIN DEPENDENT TYPE 2 DIABETES

Kaitlin Keenan; Elizabeth Pfob; Anita D. Misra-Hebert; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #3185182)

BACKGROUND: For patients with Type 2 Diabetes (T2D) not on insulin, self-monitoring of blood glucose (SMBG) does not reduce HbA1c, and has been identified by SGIM as low value care. Knowing which patients are using SMBG and whether rate of use differs across physicians can inform interventions to reduce its use.

METHODS: This retrospective study included adults with T2D who had a primary care visit at an integrated health center between 2013 and 2015. Patients were excluded in years they received an insulin prescription. Each year, we defined SMBG use based on receiving 1 prescription for blood glucose strips. We calculated the number of strips prescribed per day by multiplying the quantity of strips by the number of refills and dividing by 365. A hierarchical multivariate logistic regression clustered within patient and physician tested the relationship age, sex, race, smoking status, insurance, duration of diabetes, HbA1c value, Charlson comorbidity index and use of SMBG. To assess provider variation, we calculated the mean and 95% confidence interval (CI) for the rate of SMBG prescriptions for each provider with 30 patients. Physicians were classified as low prescribers if their 95% CI was below the mean prescribing rate and high prescribers if their 95%CI was above.

RESULTS: Our sample included 41,257 people who had a mean age of 63, were 51% female and 75% white. Use of SMBG increased slightly from 26% in 2013 to 29% in 2015 ($p<0.01$). In 2015, 48% of SMBG users were prescribed less than one strip per day. SMBG users had a higher HbA1c than non-users (7.2 vs 6.7, $p<0.01$) but had been diagnosed with diabetes for a similar number of years (3.6 vs 3.5). In the regression model government insurance (vs private adjusted odds ratio (AOR) 1.52, 95%CI:1.39-1.65), years with diabetes (AOR: 1.03, 95%CI: 1.02-1.04 per 1 year), increased HbA1c (AOR: 1.50, 95%CI: 1.46-1.52 per 1 point) and higher Charlson comorbidity index (AOR: 1.08, 95%CI: 1.05-1.11 per 1 point) were significantly associated with SMBG. Among patients with newly diagnosed with T2D in 2013, SMBG use was similar in 2013 and 2015 (26% vs 28%, $p=0.12$). SMBG users had higher HbA1c values than nonusers (difference = 0.42 in 2015, $p<0.01$). On average, physicians prescribed SMBG to 29% of their T2D patients not using insulin (range: 0.03% to 73%); 30% of physicians were high

prescribers and 25% were low prescribers. Fifty-three percent of patients of high prescribers had T2D more than five years compared to 38% of patients of low prescribers ($p < 0.01$).

CONCLUSIONS: There is substantial variation in rates of SMBG by physicians. The association of HgA1C with SMBG suggests physicians may believe that SMBG will lower HgA1C. Private insurance co-pays may discourage SMBG.

CHARACTERIZING FATIGABILITY IN HOSPITALIZED PATIENTS WITH ANEMIA

Micah T. Prochaska; Cyrus Alavi; Sarah Bradbury; David Meltzer. University of Chicago, Chicago, IL. (Control ID #3161008)

BACKGROUND: Fatigability describes how fatigued a patient is at any given level of activity, and is measured as the degree of fatigue a patient experiences after performing a specific amount of activity. The National Institute of Aging has suggested that fatigability is an important measure in patients with conditions where fatigue is a prominent symptom, such as hospitalized patients with anemia. This is because fatigue is the primary symptom of anemia, and both hospitalization and anemia-related fatigue are associated with declines in activity and functional capacity. As such, measuring fatigability in hospitalized patients with anemia could provide hospitalists information about the severity of patients' fatigue, and how fatigue may be interfering with their functional capacity. Moreover, fatigability could be used to predict future functional decline or disability post hospitalization. However, fatigability has not been previously described in hospitalized patients with anemia. The purpose of our study was to establish the clinical reliability of fatigability, by characterizing the association between fatigability and patient's clinical (i.e. Hb, comorbidities) and demographic characteristics.

METHODS: From 6/2017-1/2018, hospitalized general medicine patients with a Hb<10g/dL were approached for an inpatient interview at hospital admission. Fatigability was measured using the Pittsburgh Fatigability Scale (PFS). The PFS contains 10 questions that measure fatigue in the context of specific activities. PFS scores range from 0-50, with higher scores indicating greater fatigability (higher fatigue at lower activity). Patients' hemoglobin (Hb) values and clinical data were abstracted from hospital administrative data. Patients who received a transfusion prior to the PFS measurement were analyzed separately since transfusion affects Hb and could confound the association with fatigability. Linear regression was used to test the association between fatigability (PFS) as the dependent variable, and patient Hb and Charlson Comorbidity score (CCS) as predictor (independent) variables, controlling for age, race, and gender.

RESULTS: 467 patients completed the inpatient PFS. The median age of the sample was 55 (IQR 39-68) years old, 61% (n=293) were female, 77% (n=360) were African American, with a median CCS of 2 (IQR 1-5). The median PFS score of the sample was 33 (IQR 25-38), and the median Hb was 8.9g/dL. In regression models, a Hb 7-8g/dL ($b=2.7$, $p=0.04$) compared to Hb 9-10, and higher CCS ($b=0.8$, $P<0.001$) were associated with increased fatigability.

CONCLUSIONS: Severity of anemia and number of comorbidities are predictive of higher fatigability (higher fatigue at lower activity) during hospitalization. This suggests that fatigability is reliably associated with expected clinical characteristics during hospitalization, and could be measured and used by hospitalists to clinically evaluate the severity of a patient's fatigue, and how that fatigue may be affecting their functional capacity.

CHARACTERIZING GENDER-BASED DIFFERENCES IN BURNOUT AMONG PHYSICIANS IN AN ACADEMIC MEDICAL CENTER

Lisa Rotenstein¹; Elizabeth Harry¹; Paige Wickner¹; Anu Gupte¹; Bridget Neville¹; Stuart R. Lipsitz¹; Elizabeth Cullen¹; Ronen Rozenblum¹; Thomas D. Sequist²; Jessica Dudley^{1, 1}. ¹Brigham and Women's Hospital, Boston, MA; ²Partners Healthcare System, Boston, MA. (Control ID #3185855)

BACKGROUND: Burnout, a syndrome that develops in response to chronic job-related stressors, is a critical issue affecting modern physicians. Burnout has negative effects on healthcare practice and workforce availability. We sought to characterize gender-based differences in burnout among physicians at an academic medical center and to understand contributors to burnout in this population.

METHODS: In Spring 2017, an adaptation of the Stanford Physician Wellness Survey was administered to all clinical faculty (defined as actively practicing medicine) at Brigham and Women's Hospital, an academic medical center affiliated with Harvard Medical School. This survey was designed by the Physician Wellness Academic Consortium. It included validated measures of aggregate burnout (defined as a combination of emotional exhaustion and interpersonal disengagement) and professional fulfillment, as well as a single question on self-defined burnout. Demographics and data regarding previously characterized burnout drivers were also collected. Generalized estimating equations clustered by department (chi-squared or t-tests) were used to compare demographics, drivers, and outcomes between gender, while content analysis was used to analyze free-text comments.

RESULTS: Our population included 1,145 clinical faculty (610 (53.2%) men and 535 (46.8%) women; 65% response rate). A majority were under age 50. The largest departments represented were medicine (26.9%) and general surgery (10.6%). Female physicians were younger than male counterparts ($p=0.02$) and trended towards lower academic ranks ($p=0.06$). They were significantly more likely to report burnout than male physicians (227 (43.3%) vs. 199 (33.5%); $p=0.02$). This finding held for self-defined burnout (45.8% of females vs. 32.3% of males; $p<0.01$). Female physicians were less likely to report professional fulfillment (183 (34.5%) vs. 298 (49.7%); $p<0.01$). They had lower ratings of perceived appreciation ($p<0.01$), schedule control ($p<0.01$), work environment diversity ($p=0.01$), diversity and quality of departmental recruiting ($p=0.02$), and salary/benefits ($p=0.02$). Although there was not a difference in female vs. male physicians' intention to leave the institution within two years, females were more likely to report a departure would be driven by considerations around mentoring/leadership, schedule flexibility, workload expectations, and dual careers (all $p<0.05$); qualitative analysis of free-text comments furthered these conclusions.

CONCLUSIONS: Female physicians practicing in an academic medical center experience higher levels of burnout and lower professional fulfillment than their male counterparts. They perceive lower levels of appreciation, schedule control, and diversity, and have decreased satisfaction with compensation practices. Further research is needed to understand which factors most robustly predict burnout, and which interventions can mitigate these phenomena in an academic medical population.

CHARACTERIZING HIGH RISK ATRIAL FIBRILLATION PATIENTS IN A SAFETY NET INSTITUTION TO IDENTIFY TRENDS THAT MAY HELP IMPROVE ANTICOAGULATION GUIDELINE ADHERENCE AND STROKE PREVENTION

Benjamin Leon⁵; Carlos Irwin Oronce²; Joel C. Marrs³; Sarah L. Anderson⁴; Tara B. Vlasimsky¹; Samuel D. Richesin¹; Carolyn A. Valdez¹; Rebecca Hanratty¹. ¹Denver Health, Denver, CO;

²University of Rochester Medical Center, Rochester, NY; ³University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; ⁴University of Colorado Skaggs School of Pharmacy & Pharmaceutical Sciences, Aurora, CO; ⁵University of Colorado, Denver, CO. (Control ID #3179221)

BACKGROUND: Atrial fibrillation (a-fib) is associated with significant morbidity and mortality, particularly due to stroke risk. Oral anticoagulation (OAC) has been shown to reduce the risk of stroke and mortality in patients with a-fib. However, the use of OAC remains underutilized, as nearly 40% of eligible patients are not on OAC. Little has been published characterizing OAC utilization in the highest risk groups, particularly in underserved populations. The objective of this evaluation is to assess utilization of OAC among patients with a-fib in a safety net health system and characterize the highest risk groups to identify trends that may help improve anticoagulation guideline adherence.

METHODS: ICD-9 codes were used to identify patients with a-fib and at least one visit with a primary care provider from July 2012 through June 2014. CHA2DS2VASc and HAS-BLED scores were calculated using ICD-9 codes, medication lists, recent vital signs and demographics. High risk patients were defined as CHA2DS2-VASc score > 2. Among patients at the highest risk of stroke, clinical characteristics of those not on OAC were compared to those who were on OAC in a cross sectional design.

RESULTS: A total of 867 patients with a-fib were identified, a large proportion of whom were at high risk for stroke with a CHA2DS2VASc score > 2 (85% of total a-fib population). Of this high-risk group, 35% of patients were not on OAC. When comparing the high-risk groups based on OAC status, there was no significant difference between the two groups based on many baseline characteristics including age, race, gender, renal function or liver function. In addition, average HAS-BLED scores were similar between the two groups. High-risk patients who were not on OAC were less likely to have heart failure and more likely to be prescribed an anti-platelet agent (both p<0.05). There were a significantly greater proportion of patients with a CHA2DS2VASc score of 2 not on OAC. However, no significant difference was seen in OAC status between CHA2DS2VASc scores for those with higher scores (CHA2DS2VASc > 3).

CONCLUSIONS: Despite high-risk status, over one-third of these patients were not on OAC. Patients not receiving OAC were more likely to be prescribed an anti-platelet agent and less likely to have heart failure, but bleeding risk as assessed by the HAS-BLED score was not associated with OAC status. More patients with CHA2DS2VASc scores of 2 were not anti-coagulated, which may be due to patients recently entering that risk category, either by age or other comorbidities, and not having their risk re-evaluated. There may be unmeasured factors that explain why these patients were not on OAC, which could guide future interventions to help improve guideline adherence.

CHARACTERIZING INPATIENT ADMISSIONS FOR NATIVE AMERICANS CARED FOR OUTSIDE THE INDIAN HEALTH SERVICE

Joshua N. Wadlin¹; Matthew Tobey²; Scott Wright³. ¹Johns Hopkins School of Medicine, Baltimore, MD; ²Massachusetts General Hospital, Boston, MA; ³jhusom, Baltimore, MD. (Control ID #3179541)

BACKGROUND: Native Americans (NAs) in the US experience substantial health disparities such as the highest prevalence of type 2 diabetes of any racial or ethnic group and a lower life expectancy than the general population. Out of estimated 5.2 million NAs in the US, 3.7 million qualify for Indian Health Service (IHS) benefits, but only 2.2 million receive care from IHS. The IHS periodically publishes data on health trends which helps to identify areas of need and targets for future interventions. These data do not include NAs who do not receive care at the IHS. The remaining millions of NAs represent a cohort whose healthcare data are poorly understood. We

sought to describe reasons for admissions and related outcomes for NAs compared to whites in the US.

METHODS: We used data from the 2014 National Inpatient Sample (NIS), a representative sample of hospital discharges across the US which excludes episodes of care at federal hospitals including IHS. We conducted a descriptive analysis, exploring the most common diagnoses for inpatient admission for NAs and compared differences in outcomes for NAs with those of whites. We identified the 10 most common reasons for adult, non-obstetric admissions for NAs, stratified by age (adults 18 to 64 and 65 or older), and compared these to results for whites, exploring differences in reasons for admission. We then evaluated the outcomes of in-hospital mortality, length of stay (LOS), and hospital charges for admissions with one of the 10 most common diagnoses for NA. We compared outcomes between NAs and whites using univariate regression for LOS and charges and chi-squared tests for mortality, each stratified by age group.

RESULTS: The most common diagnoses for NAs <65 were septicemia, alcohol-related, complication of diabetes, mood disorder, and skin/soft tissue infection. The most common diagnoses for 65 and older were septicemia, pneumonia, CHF, osteoarthritis, and COPD. In an unadjusted model for those <65 with one of the top 10 diagnoses, compared to whites (n=1,704,805), NAs (n=20,124) had a higher mortality (2.33% v 1.59%, p<0.001), a longer mean LOS (5.25 v 5.03 days, p=0.01), and lower mean total charges \$40,416 v \$43,032, p=0.007). For those 65 or older, mortality was not significantly different between NAs (n=9,768) and whites (n=1,836,672), but NAs had a longer mean LOS (5.21 v 4.89 days, p <0.001) and lower mean total charges (\$45,357 v \$48,792, p=0.002).

CONCLUSIONS: This analysis identified the top reasons for adult, non-OB admission among NAs receiving care outside the IHS. It also identified differences in outcomes for NAs compared to whites with the same primary diagnosis. Because length of stay is a critical driver of hospital charges, it is noteworthy that NAs had longer LOS yet lower charges. The higher mortality for NA adults <65, suggests a particularly vulnerable population. Poor access to care and other social determinants of health may explain some of these variations, but more research is needed to understand these differences.

CHARACTERIZING TRENDS IN PRIMARY CARE VISITS USING NAMCS 2007-2015

Aarti Rao¹; Zhuo Shi²; Kristin N. Ray³; Ateev Mehrotra^{2, 5}; Ishani Ganguli⁴. ¹Icahn School of Medicine, New York, NY; ²Harvard Medical School, Boston, MA; ³University of Pittsburgh, Pittsburgh, PA; ⁴Brigham and Women's Hospital, Chestnut Hill, MA; ⁵Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #3162916)

BACKGROUND: Supporting primary care has been a focus of policy reforms in the United States. However, recent evidence suggests a decline in primary care visits per capita. We examined factors underlying the decline and in particular, the role of changing physician practice.

METHODS: Using 2007-2015 National Ambulatory Medical Survey (NAMCS) data, we examined visits to a primary care physician (PCP) (i.e. internal medicine, family practice, or pediatrics) by patients 18 years old. We calculated visits per capita by dividing number of visits by annual US Census estimates for each population subgroup and used rolling averages to minimize yearly fluctuations (e.g. 2008 estimate included 2007-2009 data). We estimated visit rates stratified by patient demographic groups. We examined visit duration and the number of diagnoses and medications addressed per visit. We also examined visit disposition and the percentage of PCPs using email consults. For each outcome, we used ordinary least-squares regression to estimate linear time trends and assessed statistical significance at p<0.05. Analyses were performed using Stata version 14.1.

RESULTS: Our weighted sample represented 2.2 billion PCP visits. Over 9 years, visit rates declined by 18.9 visits per 100 patient years (-0.04 per year; 95% CI -0.05,-0.02) with similar declines across sex and age groups. We

found increases in visit duration (0.41 min per year; 95% CI 0.20,0.64) and in number of diagnoses (0.04 per year; 95% CI 0.01,0.06) and medications (0.12 per year; 95% CI 0.06,0.16) addressed. We found a decline in visits per capita in which PCPs recommended follow-up (-0.03 per year; 95% CI -0.04,-0.02). A larger proportion of PCPs reported using email consultations over time (1.7% per year; 95% CI 1.2,2.2).

CONCLUSIONS: Over time PCP visits were longer, more issues were addressed per visit, and physicians were less likely to suggest follow-up. These findings suggest that the declining PCP visit rate may be partially explained by PCPs providing more comprehensive in-person care and using more non-face-to-face care such as email. Our findings are limited by physician self-report and potential changes in billing practice that may contribute to a rise in self-reported diagnoses.

CHRONIC CONDITIONS AND PHYSICAL FUNCTIONING: DEVELOPMENT OF A NEW ICD-CODED MULTIMORBIDITY INDEX FOR USE IN ADMINISTRATIVE CLAIMS DATA

Melissa Y. Wei^{1, 2}; Jamie Luster¹; David Ratz³; Kenneth Lang^{1, 2}. ¹University of Michigan, Ann Arbor, MI; ²Institute for Healthcare Policy and Innovation, University of Michigan, Ann Arbor, MI; ³Veterans Affairs Ann Arbor Healthcare System, Ann Arbor, MI. (Control ID #3179958)

BACKGROUND: Most older adults have multimorbidity, the co-existence of multiple chronic conditions, that profoundly affect physical functioning. Physical functioning is a universal health value that strongly predicts poor health outcomes and is linked to multimorbidity in aging adults. However, it is not consistently available in administrative data. We previously developed and validated a multimorbidity index that weights self-reported physician-diagnosed diseases by physical functioning. Although the multimorbidity-weighted index (MWI) has been extensively validated, its use is currently limited to self-reported conditions. Herein, we aimed to develop an ICD-coded MWI (MWI-ICD) for use in administrative claims data and compare its performance with traditional multimorbidity metrics.

METHODS: We linked Health and Retirement Study (HRS) and Medicare claims to develop a multimorbidity index of ICD-coded conditions (MWI-ICD) for administrative data. Medicare-eligible HRS participants with at least two outpatient claims or one inpatient claim within two years contributed repeated measures of ICD-9-Clinical Modification chronic conditions and a modified Short Form-36 10-item physical functioning scale between 2000-2012. Mixed effects models adjusted for age and all other ICD-coded chronic conditions were used to obtain regression coefficients for conditions on physical functioning. Conditions that were inversely associated with physical functioning and stably estimated were retained in the final model. MWI-ICD was calculated by summing the physical functioning-weighted conditions for each participant. We compared the distribution and performance of MWI-ICD with a simple (i.e., unweighted) disease count.

RESULTS: We included 71,756 observations from 17,478 participants with mean age 70.3 (SD 7.2) years and 56.0 (SD 30.3) physical functioning units. We considered 409 ICD-coded chronic diseases and conditions in the initial analysis and narrowed this to 143 in the final model. Diseases varied several-fold in their impact on physical functioning (median 1.3, range 0.03-17.3). The top prevalent conditions were hypertensive disease (73%), osteoarthritis (43%), other disorders of kidney and ureter, urethra and urinary tract, and bladder (41%), and coronary atherosclerosis (36%). ALS, allergic arthritis, female genitourinary cancers, hemiplegia/paraplegia, and Parkinson disease had the greatest impact on physical functioning. The mean MWI was 14.0 (median 10.3, range 0-100.1) and mean simple disease count was 8.3 (median 6, range 0-40).

CONCLUSIONS: ICD-coded chronic conditions from Medicare claims had wide-ranging associations with physical functioning. MWI had a

wider distribution than simple disease count, suggesting that a simple disease count is unlikely to capture the full impact of multimorbidity on physical functioning. A newly-developed multimorbidity index based on ICD-coded chronic conditions is feasible and readily implemented in administrative claims data.

CLINICAL ARCHITECTURE INTERVENTION INCREASES TOBACCO CESSATION IN PRIMARY CARE

Richard Altman²; Melanie D. Whittington³; Lauren Drake²; Hillary Chrastil³; Carmen L. Lewis¹. ¹University of Colorado, Denver, CO; ²University of Colorado, Lone Tree, CO; ³University of Colorado, Aurora, CO. (Control ID #3180280)

BACKGROUND: Tobacco cessation is a high value intervention but clinician counseling in primary care practices is suboptimal. Our goal was to determine whether a clinical architecture intervention that includes reliable medical assistant (MA) tobacco data sent to clinicians' notes at the point of care is associated with an increase in tobacco cessation in primary care.

METHODS: We implemented the clinical architecture intervention in one internal medicine clinic and compared outcomes to two other primary care practices in the same health care system. The clinical architecture intervention paired MA data collection on current tobacco status with a clinician "action" tool. The clinician action tool pushed MA information to the assessment and plan section of the clinician's note, acting as a prompt for the clinician during the visit. The action tool had a drop-down menu with documentation for 1) tobacco cessation addressed and plan description 2) tobacco use not addressed, and 3) "wildcard" so that clinicians could provide their own documentation. Using electronic health record data, we identified patients who had an index visit within the practices from 4/2017 to 4/2018 and who reported tobacco use. We compared self-reported tobacco use for these patients at follow up visits between 90 -179 days and 180 to 359 days from the index visit in intervention and control practices. Propensity score matching (on age, gender, zip code, and duration of follow-up) was used to match patients at the intervention practice to comparable patients in the two control practices. Logistic regression was used to estimate the association between the intervention and tobacco use at the first follow-up visit (90-179 days) and the second follow-up visit (180-360 days). A difference in differences specification was used to control for temporal trends. Standard errors were clustered at the provider level.

RESULTS: We identified 538 patients that used tobacco at the index visit in the intervention practice and 1,647 tobacco users in the control practices. One hundred sixty-six patients (31%) in the intervention and 500 patients (31%) in the control practices had a first follow up visit. For the second follow up visit, 142 (26%) and 388 (24%) patients had a follow up visit in the intervention and control practices, respectively. The intervention was associated with a 10% ($p=0.006$) reduction in tobacco use at the first follow-up visit and a 6% reduction at the second follow-up visit ($p=0.121$).

CONCLUSIONS: Our clinical architecture intervention was associated with a statistically significant reduction in reported tobacco use at the first follow-up visit. A reduction, although not quite significant, was also observed at the second follow-up visit. Having actionable tobacco data for clinicians within the assessment and plan at the point of care may help to facilitate tobacco cessation for primary care patients.

CLINICAL IMPACT OF LAUNCHING A NEW PALLIATIVE CARE SERVICE AT A REGIONAL HOSPITAL: THE GRAND STRAND MEDICAL CENTER EXPERIENCE

DR. TYLER KILGORE; DR. ELIJAH ENGWALL; DR. VINOD NAMBUDIRI

Tyler Kilgore; Elijah Engwall; Vinod E. Nambudiri. Grand Strand Medical Center, Myrtle Beach, SC. (Control ID #3182877)

BACKGROUND: Inpatient Palliative Care (PC) services have been shown to reduce cost and increase patient satisfaction in cases that vary in clinical nature and course. However, data suggests that PC teams are underutilized, whether by delays in appropriate consultation or lack of involvement entirely. We sought to characterize the clinical impact of a PC service team in the first months of introduction at a regional medical center by examining timing of consultations, changes in patient code status, and patient destination at discharge.

METHODS: We conducted a retrospective, descriptive chart review analysis of all cases on which PC was consulted from its introduction in 3/2016 through 12/2016. 213 cases were reviewed. Patient demographics, diagnoses, length of stay (LOS), LOS prior to PC consultation, code status and destination at discharge were reviewed. Information was compared to national data available from the National Palliative Care Registry.

RESULTS: 82% of patients consulted were Caucasian and 13% African American, similar to the overall demographics at our institution. 40% of all patients who received an inpatient PC consult expired during hospitalization; 37% were discharged to home or hospice, and 22% were discharged to another medical facility. The most common primary diagnoses for individuals who received PC consults were Hematologic/Oncologic disease (25%), Neurologic disease (23%), Cardiopulmonary disease (17%), Infectious disease (11%), and Trauma/Overdoses (9%). Change in code status was observed frequently; nearly 25% of patients who received a PC consultation had their code status changed to DNR and over 50% of individuals had DNR statuses prior to consultation. In no case was a DNR patient changed to Full Code. Following PC consultation, the vast majority of patients (86%) did not undergo any further life prolonging procedures such as intubation, blood transfusion, paracentesis, PEG tube, or cardiac catheterization.

CONCLUSIONS: Our data demonstrates the multifaceted impact of a new PC consult team in a regional hospital. Palliative care consultation was associated with marked reductions in life prolonging procedures and frequent change of code status to DNR. During the study period, the inpatient mortality rate of the PC service was twice that reported in national registries. This likely indicates a tendency for a new PC service to be consulted later in the course of care than the national average, and speaks to ongoing needs to address underutilization of PC services for end of life care. Finally, nearly 10% of consults at our center were for trauma/overdose, a category not featured in the national palliative care registry, and may speak to local demographics and the profound impact of the opioid crisis on shaping care delivery locally.

CLINICAL TRIAL EVIDENCE SUPPORTING FDA APPROVAL OF NEW DRUGS OVER THREE DECADES, 1995-2017

Audrey Zhang³; Jeremy Puthumana¹; Nilay Shah²; Joseph S. Ross¹. ¹Yale University School of Medicine, New Haven, CT; ²Mayo Clinic, Rochester, MN; ³New York University School of Medicine, New York, NY. (Control ID #3183972)

BACKGROUND: The US Food and Drug Administration (FDA) possesses regulatory flexibility in determining the evidence necessary to support new drug approval. This has increasingly been exercised through special regulatory programs, such as Accelerated Approval and Breakthrough Designation. These permit the use of different clinical evidentiary standards to support approval, such as surrogate markers of disease (e.g. biomarkers) rather than clinical (e.g. overall survival) endpoints. This study examined whether clinical trial evidence supporting FDA approval of new drugs has changed over three decades.

METHODS: We performed a cross-sectional analysis of all new drugs (small molecule and biologic) approved by the FDA between 1995-1997, 2005-2007, and 2015-2017. Using the publicly-available Drugs@FDA database, we identified drug approvals and classified them by therapeutic area and use of special regulatory programs. Next, we identified the pivotal efficacy

trials supporting each drug's approval, and characterized use of randomization, double-blinding, choice of comparators and endpoints, number of participants, and trial duration. Comparisons between time periods were performed using chi-square and Kruskal-Wallis tests. Analyses were repeated aggregated by indication and stratified by product therapeutic area and use of special regulatory programs.

RESULTS: We identified 273 new drugs approved by the FDA in these 3 periods, representing 339 indications supported by 802 pivotal efficacy trials. The proportion of approvals receiving priority review increased from 1995-1997 to 2015-2017 (34% vs. 61%; p<0.001), as did those receiving an orphan designation (13% vs. 38%; p<0.001). Rates of accelerated approval did not differ (11% vs. 17%; p=0.23). The most common therapeutic area for approvals differed over time (infectious disease [34%] in 1995-1997 vs. oncology [27%] in 2015-2017; p=0.002). The median number of pivotal trials supporting an indication decreased from 2 (IQR 2-3) to 1 (IQR 1-3; p<0.001). The proportion of indications based on at least one pivotal trial using an active comparator decreased (57.3% vs. 30.2%; p<0.001), whereas use of only single-arm trials increased (4.0% vs. 17.0%; p=0.005). The median number of enrolled patients per indication remained steady (774 [IQR, 464-1314] vs. 816 [IQR, 199-2112]; p=0.47). The proportion with at least one pivotal trial of at least 6 months' duration increased (25.8% vs. 46.2%; p=0.006). Differences in pivotal trial characteristics over time were consistent in analyses stratified by therapeutic area and use of special regulatory programs.

CONCLUSIONS: Clinical trial evidence supporting new drugs at the time of approval has changed over time, in part reflecting increasingly flexible evidentiary standards. This was consistent regardless of use of special regulatory programs. Diminished quantity and quality of premarket evidence suggests an increasing need for continued evaluation after market approval.

CLINICIAN-EDUCATOR CAREER PATHS: THE IMPACT OF ADVANCED EDUCATION TRAINING ON ACADEMIC SUCCESS AND CAREER SATISFACTION

Daniella A. Zipkin¹; Subha Ramani²; Corrie A. Stankiewicz³; Margaret C. Lo⁴; Alia Chisty⁵; Irene Alexandraki⁶; Maria A. Wamsley⁷; Scott D. Rothenberger⁸; Kwonho Jeong⁸; Carla Spagnoli⁸. ¹Duke University, Durham, NC; ²Brigham and Women's Hospital, Harvard Medical School, Boston, MA; ³University of Pennsylvania SOM, Narberth, PA; ⁴University of Florida College of Medicine, Gainesville, FL; ⁵Temple, Philadelphia, PA; ⁶Florida State University College of Medicine, Tallahassee, FL; ⁷University of California, San Francisco, San Francisco, CA; ⁸University of Pittsburgh, Pittsburgh, PA. (Control ID #3184925)

BACKGROUND: Clinician-educator career paths are varied. Some faculty pursue additional training in medical education through programs offered by professional medical organizations, certificate programs, clinician-educator fellowships, or advanced degrees in education. It is unclear whether such preparation impacts academic advancement, job satisfaction, or leadership opportunities.

METHODS: Using a mixed-methods approach we explored the impact of medical education training on subsequent academic achievements, leadership, and job satisfaction among clinician-educators in internal medicine. We distributed an online survey to the Society of General Internal Medicine (SGIM) membership in the fall of 2017, and conducted two in-person focus groups of a subset of survey respondents at the 2018 SGIM Annual Meeting. We used multivariate analysis for quantitative data and thematic analysis of qualitative data. We created an "intensity of training" metric to categorize the type of additional training, with clinician-educator fellowships and Master's in medical education considered to be highest intensity, longitudinal training courses as intermediate intensity, and local faculty development as low intensity.

RESULTS: 198 clinician-educators completed the survey. 64% were female with 59% in the 36-55 year age range. 16% had a Masters degree in medical education. 42% had completed fellowship with 67% of those being in

education, and 87% percent had participated in some faculty development in education, with the majority reporting local training opportunities. Women were more likely than men to have completed a fellowship and/or Master's degree in medical education.($p=0.029$). Advanced training was associated with more publications ($p=0.002$), lectures or workshops at the regional, national or international level ($p=0.001$), and regional or national committee memberships ($p=0.04$). Having an education leadership role was not associated with additional training, with the exception of a Dean's office role ($p=0.029$). Over 70% of respondents indicated a positive impact of additional training on career achievement and job satisfaction, with greater positive perception in those with higher levels of additional training ($p<0.001$). Qualitative data exploring factors viewed as influencing clinician-educators' career advancement were grouped under the major thematic categories of: (1) passion for teaching, (2) institutional culture and (3) advanced training and its impact. Themes within these categories suggest variation in institutional and generational expectations regarding carving out time for education, promotion, and obtaining leadership roles. Detailed description of themes will be provided in the full abstract.

CONCLUSIONS: Clinician-educators participate in a wide array of additional training opportunities. Advanced training is associated with scholarly productivity and perceived job satisfaction, but not acquisition of most leadership roles. Variations in institutional culture may explain this discrepancy.

CLINICIAN-LEVEL VARIATION IN THREE MEASURES REPRESENTING OVERUSE BASED ON THE AMERICAN GERIATRICS SOCIETY CHOOSING WISELY STATEMENT

Theresa A. Rowe¹; Ji Young Lee¹; Tiffany Brown²; Stephen Persell³. ¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³Northwestern University, Evanston, IL. (Control ID #3173753)

BACKGROUND: The extent of clinician-level variation in the overuse of testing or treatment in older adults is not well understood. The objective is to examine the clinician-level variation on three measures of overuse in older adults.

METHODS: The study was a retrospective analysis of two process and one outcome measures in adults aged 65 years and older evaluated in outpatient primary or immediate care within a health system affiliated with an academic medical center between July 1, 2016 and June 30, 2017. Subjects: Clinicians: Primary or immediate care clinicians caring for adults aged 65 years and older. Patients: Women and men aged 65 years and older being seen in a primary or immediate care clinic. Measures: The primary outcomes of interest were three electronic clinical quality measures taken from electronic health record data representing potentially inappropriate use of medical services in older adults: prostate specific antigen screening in men age 76 and older (PSA), urine culture or urinalysis for non-specific reasons in women age 65 and older (UC/UA), and hemoglobin A1c less than 7.0 in adults age 75 and older with diabetes treated with insulin or oral hypoglycemic medication (DM). Physicians, advanced practice nurses and physician assistants with at least 10 eligible cases were included in the analysis.

RESULTS: There were 42 to 144 clinicians (mostly physicians) and 665 to 5933 patients included in the analysis per measure. Variation at the physician level was highest for PSA (intraclass correlation coefficient [ICC] = 0.27), followed by UC/UA (ICC = 0.18), and lowest for DM (ICC = 0.024). The percentage of patients with overuse attributed to the lowest and highest overusing quartile of clinicians were: 8% and 54% for PSA, 3% and 35% for UC/UA and 13% and 49% for DM, and the odds ratio of overuse in highest quartile compared to the lowest were 99.3 (95% CI 43 to 228), 15.7 (10 to 24), and 6.0 (3.3 to 11), respectively.

CONCLUSIONS: Within the same health system, overuse of testing and treatment in older adults varied greatly across clinicians, particularly for the process measures examined.

COLLECTIVE VULNERABILITY IS ASSOCIATED WITH HIGHER PERCEIVED DISCRIMINATION, PAIN, AND DEPRESSION IN VETERANS WITH OSTEOARTHRITIS

Utile R. Essien^{1, 2}; Ada O. Youk^{3, 2}; Said Ibrahim⁴; Leslie R. Hausmann². ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA; ⁴Weill Cornell Medicine, New York, NY. (Control ID #3177582)

BACKGROUND: Perceived discrimination is associated with physical and mental health outcomes, including chronic pain and depression, and plays a role in racial health disparities. However, little is known about how the intersection of race and other factors for which one might experience discrimination (collective vulnerability), such as gender, education, income, weight, or disability, impact health. Our aim was to examine the additive effects of six vulnerable group memberships on perceived discrimination, pain, and depression and to test whether perceived discrimination mediates the impact of collective vulnerability on pain and depression.

METHODS: Our sample included patients at two large VA medical centers who enrolled in a randomized controlled trial testing a positive psychological intervention for chronic pain. Participants were white and African American Veterans aged 50 years reporting symptomatic knee osteoarthritis (OA). At baseline, we measured perceived discrimination using the Everyday Discrimination Scale; severity of pain using the pain subscale of the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC); depression severity using the Personal Health Questionnaire Depression Scale (PHQ-8); and demographic variables (self-reported gender, age, race, income, education, and employment). We abstracted body mass index (BMI) from medical records. We assigned binary indicators of vulnerability to participants with each of the following characteristics: African American race, female gender, high school education or less, <\$20,000 income, disabled employment status, and morbid obesity (BMI>40). We then summed individual indicators to capture each participant's number of vulnerabilities. We conducted separate linear regression models to assess the relationship between the number of vulnerabilities and measures of perceived discrimination, pain, and depression. Lastly, we used Sobel's test of mediation to examine perceived discrimination as a mediator of the relationships between collective vulnerability and pain and depression.

RESULTS: Among the 517 participants (47.8% white, 52.2% African American), the average number of vulnerabilities was 1.66 (SD=1.17). Number of vulnerabilities was significantly associated with perceived discrimination (Coef = 0.41, 95% CI 0.18, 0.65), pain (Coef = 4.14, 95% CI 2.92, 5.37) and depression severity (Coef = 1.13, 95% CI 0.74, 1.51). Although perceived discrimination significantly explained 16.9% of the association between vulnerabilities and depression (p -value <0.01), it did not mediate the association with pain (p -value =0.10).

CONCLUSIONS: Among Veterans with chronic pain from OA, collective vulnerability is associated with higher levels of perceived discrimination, pain, and depression. Perceived discrimination also partially mediates the relationship between vulnerabilities and depression. Further understanding of how vulnerabilities combine to worsen physical and mental health outcomes is warranted.

COLORECTAL CANCER SCREENING: IMPACT OF PROVIDER FACTORS AND STATE-LEVEL COLORECTAL CANCER SCREENING RATES ON MULTI-TARGET STOOL DNA TESTING COMPLIANCE AMONG MEDICARE BENEFICIARIES

Rebecca Swartz¹; Emily Weiser¹; Philip Parks¹; Jack Van Thomme¹; Paul Limburg^{1, 2}; Barry M. Berger¹. ¹Exact Sciences, Madison, WI; ²Mayo Clinic, Rochester, MN. (Control ID #3180325)

BACKGROUND: The multi-target stool DNA (mt-sDNA) test is a noninvasive colorectal cancer (CRC) screening test included in United States Preventive Services Task Force, American Cancer Society, and Multi-Society Task Force guidelines for average-risk adults ages 50 years and older. Mt-sDNA testing is performed by a single national reference laboratory (Exact Sciences Laboratories LLC [ESL], Madison, WI) and has an embedded patient navigation system (compliance program) supporting test completion through patient education, reminders, outreach, and multilingual support. Provider specialty and state-level CRC screening rate associations with mt-sDNA test compliance in the Medicare population is reported here. Medicare covers mt-sDNA screening with no out-of-pocket expenses, mitigating the potential impact of financial barriers on compliance.

METHODS: Medicare beneficiaries ages 65-85 years with a valid mt-sDNA order from September 1, 2016-August 31, 2017 were identified from the ESL database. Compliance was defined as completion of mt-sDNA testing (positive or negative result) within 365 days of order date. Time to compliance (TTC) was days from order date to completion of mt-sDNA testing. Associations between compliance and provider specialty were evaluated using descriptive statistics. Mt-sDNA compliance was compared for providers in states having the highest (ME [75.9%], CT [75.8%], and MA [75.3%]) and lowest (MS [59.9%], OK [58.8%], and NM [58.5%]) overall CRC screening rates.¹

RESULTS: The mt-sDNA test compliance rate was 71.1% for the study population (N=368,494). Internal medicine (IM) and family medicine (FM) practitioners ordered 74.6% of mt-sDNA tests, with a TTC of 27 days for both specialties. IM practitioners had a 70.7% compliance rate, and FM practitioners had a 71.4% compliance rate. Compliance was highest (78.4%) and median TTC was lowest (25 days) for mt-sDNA tests ordered by gastroenterologists. Compliance in states with high (>75%) and low (<60%) CRC screening rates were similar. Mt-sDNA test compliance rates for ME, CT, and MA, respectively, were 73.7%, 68.2%, and 68.3% (median TTC of 28, 28, and 29 days). The mt-sDNA test compliance rates for MS, OK, and NM, respectively, were 70.1%, 72.3%, and 72.6% (median TTC of 25, 26, and 28 days).

CONCLUSIONS: These data suggest that provider specialty is associated with mt-sDNA test compliance. Gastroenterologists had higher compliance rates than IM and FM practitioners, possibly due to differences in patient factors (eg, patients completing gastroenterology referrals may have more motivation to complete CRC screening or a greater sense of urgency) and/or provider factors (eg, patient appreciation of specialty knowledge). Mt-sDNA test compliance was similar in states with both high and low overall CRC screening rates. Broader adoption of mt-sDNA testing may help improve participation among Medicare beneficiaries, especially in states with lower than average screening rates.

COMBINED PATIENT - PROVIDER ENGAGEMENT SYSTEM AND MHEALTH INTERVENTIONS IMPROVED MEDICATION ADHERENCE FOR MINORITY AND LOW-INCOME PATIENTS WITH DIABETES COMPARED TO MHEALTH ONLY: THE OFFICE-GUIDELINES APPLIED TO PRACTICE PROGRAM

Khader Herzallah; Amari Ellsworth; Zane Alroshood; Ngoc Nguyen; Karen Kelly-Blake; William Hart-Davidson; Ling Wang; Sherif Elkinany; Ade B. Olomu. Michigan State University, East Lansing, MI. (Control ID #3183109)

BACKGROUND: Approximately 21-42% of patients with diabetes (DM) do not take their medications as prescribed. Current implementation studies suggest that mHealth interventions alone may not be enough to improve patient health outcomes. Our objective was to determine the impact of a combined patient activation program

(Office-Guidelines Applied to Practice {Office-GAP}) + mHealth in improving medication adherence compared to mHealth alone for minority and low-income populations.

METHODS: Office-GAP intervention included: 1) Patient activation group visit 2) Physician training for patient activation, and 3) Decision support checklist used in real time in the office. mHealth intervention was teaching patients to send and receive text messages; patients received daily messages appropriate to their diagnosis and medications for 14 weeks along with appointment reminders. Diabetic patients with A1c >8 or with uncontrolled hypertension (BP > 130/80) attending Internal Medicine Residency Clinics were recruited into the study. Patients were consecutively assigned to combined Office-GAP + mHealth group (Green) or mHealth only group (White) based on the resident clinic designation. After a group visit, patients followed up with two physician visits over a 4-month period. Medication adherence was compared at baseline and follow-up by two validated adherence scales: 1) Adherence to Refills and Medications Scale (ARMS), a 14-item scale with two subscales for taking medications as prescribed and refilling medications on schedule, and 2) Morisky Medication Adherence Scale (MMAS), a 4-item self-report measure of adherence to all prescribed medications.

RESULTS: Seventy-one patients enrolled in the pilot study; 37 were Office-GAP + mHealth (Green) arm and 34 mHealth alone (White) arm at baseline. At 4 months follow-up, 20 patients from Green and 18 patients from White completed ARMS. Nineteen from Green and 19 from White completed MMAS. Regression analysis for ARMS show that after adjusting for relevant clinical variables, from baseline to 4 months follow-up, ARMS in Green group decreased significantly with 1.74 points on average (P-value=0.008) signifying better adherence to refills and medications. In White group, ARMS increased by 0.256 points (P-value=0.80). Compared with White group, ARMS in Green group are 2.0 points lower from baseline to follow-up (P-value=0.09). Poisson regression results for MMAS show that from baseline to follow-up, the Incident Rate Ratio (IRR) of MMAS in Green group is 0.762 (P=0.05), while IRR in White group is 1.09 (P=0.44). Compared with White group, IRR of MMAS in Green group from baseline to follow-up is 0.72 (P=0.045) indicating improved medication adherence.

CONCLUSIONS: Combined Office-GAP + mhealth significantly improved adherence to refills and to all prescribed medications compared to mhealth alone. Our study suggests that the combined intervention shows promise to improve health outcomes for patients with diabetes.

COMMUNICATING CARDIOVASCULAR RISK TO HIGH RISK CANCER SURVIVORS: A MIXED METHODS PILOT STUDY OF A STATIN RISK COMMUNICATION TOOL

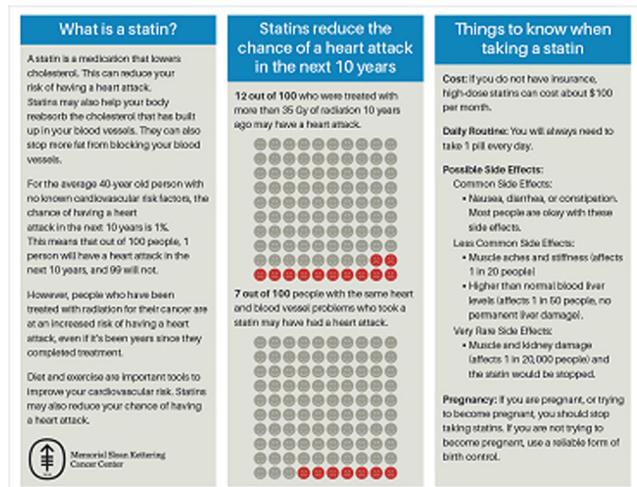

Nirupa J. Raghunathan²; Emily Zabor³; Kevin Oeffinger¹; Emily S. Tonorezos²; Deborah R. Korenstein². ¹Duke University, Durham, NC; ²Memorial Sloan-Kettering Cancer Center, New York City, NY; ³Memorial Sloan Kettering Cancer Center, New York, NY. (Control ID #3182633)

BACKGROUND: Over a million survivors of childhood, adolescent, and young adult cancer live in the US; many were treated with radiation therapy (RT). RT with fields including the coronary arteries is a risk factor for cardiovascular disease (CVD). Survivors may be unaware of their high CVD risk or how to mitigate it; tools are needed to improve understanding. The Institute of Medicine recommends decision aids to optimize patient discussions of therapies. We developed and pilot tested a risk communication tool to improve shared decision making in high-risk survivors regarding CVD risk reduction with statin therapy. We included quantitative and qualitative arms to inform development and testing of the tool.

METHODS: The statin risk communication tool was adapted from a previously validated tool. Participants were recruited from Memorial Sloan Kettering Cancer Center into two arms: control CVD risk discussion vs. tool-facilitated discussion. All patients were at increased risk for CVD due to history of chest RT. The post-visit survey used Likert-like scales to explore patient perceptions of statins and included knowledge questions and a decisional conflict scale. This feasibility and acceptability study used descriptive statistics and was not powered for significance. Semi-structured interviews with intervention arm participants explored the shared decision-making process.

RESULTS: Median participant (n= 46) age was 45. Most intervention patients (22/24, 92%) and 50% (11/22) of controls found statin information acceptable while 31% (7/22) of the control arm selected "not applicable" regarding information acceptability. Most participants were unaware of their CVD risk or statin side effects. In semi-structured interviews participants found the tool helpful to visualize risk and aid physician conversations; they expressed apprehension at starting a statin and comfort in decision-making.

CONCLUSIONS: This risk communication tool was acceptable. Many receiving usual care often not recall a conversation, suggesting an absent or forgettable discussion. Knowledge of CVD and statins was poor. Qualitative data suggested the tool improved decisional clarity and comfort.

Statin Risk Communication Tool

COMMUNITY PHARMACY MEDICATION REVIEW, DEATH AND READMISSIONS AFTER HOSPITAL DISCHARGE

Lauren Lapointe-Shaw^{1, 1}; Chaim M. Bell^{1, 2}; Peter C. Austin^{3, 1}; Petros Pechlivanoglou^{1, 6}; Lusine Abrahamyan^{1, 4}; Ping Li³; Noah M. Ivers^{1, 5}; Donald Redelmeier^{1, 7}; Lisa Dolovich¹. ¹University of Toronto, Toronto, ON, Canada; ²Sinai Health System, Toronto, ON, Canada; ³ICES, Toronto, ON, Canada; ⁴Toronto Health Economics and Technology Assessment (THETA) Collaborative, Toronto, ON, Canada; ⁵Women's College Hospital, Toronto, ON, Canada; ⁶SickKids Research Institute, Toronto, ON, Canada; ⁷Sunnybrook Health Sciences Centre, Toronto, ON, Canada. (Control ID #3180233)

BACKGROUND: In-hospital medication review has been linked to improved outcomes after hospital discharge, yet there is little evidence to support the use of community pharmacy-based interventions as part of transitional care. MedsCheck, a program of medication reconciliation and review by community pharmacists, was introduced

throughout the province of Ontario in 2007. Our objective was to determine if discharged patients receiving MedsCheck had lower rates of subsequent death or readmission than patients not receiving it.

METHODS: This was a population-based retrospective cohort study of eligible patients discharged home from an Ontario hospital from April 1st 2007 to September 16th 2016. Eligible patients were at least 66 years of age on the day of hospital discharge and filled a prescription at a community pharmacy within 7 days of discharge. Propensity score matching was used to ensure comparability of groups with respect to demographics, comorbidities, previous healthcare usage, hospitalization, hospital and pharmacy characteristics. The exposure of interest was receipt of MedsCheck, a publicly-funded medication reconciliation and review encounter provided by community pharmacists. The primary outcome was time to death or readmission, with the latter defined as an emergency department visit or urgent re-hospitalization, within 30 days of MedsCheck receipt. Secondary outcomes were time to adverse drug event and the 30-day count of outpatient physician visits.

RESULTS: Of 879,497 unique patients discharged, 77,459 (8.8%) received a MedsCheck. Of these, 67,163 patients (86.7%) were propensity score-matched 1:1 to patients who did not receive a MedsCheck. Patients who received MedsCheck had a lower risk of 30-day death or readmission than controls (23.4% vs 23.9%, HR 0.97, 95% CI 0.95-1.00, p=0.02), driven by a decreased risk of death (1.7% vs 2.1%, HR 0.79, 95% CI 0.73-0.86) and re-hospitalization (11.0% vs 11.4%, HR 0.96, 95% CI 0.93-0.99). There was no significant difference in 30-day return to the emergency department (22.5% vs 22.8%, HR 0.99, 95% CI 0.96-1.01). There was no difference in adverse drug events associated with MedsCheck status (1.5% vs 1.5%, HR 1.03, 95% CI 0.94-1.12). MedsCheck recipients had more outpatient visits than controls (mean 2.11 vs 2.09, RR 1.01, 95% CI 1.00-1.02, p=0.02).

CONCLUSIONS: Among older adults filling a prescription after hospital discharge, receipt of a pharmacy-based medication reconciliation and review encounter was associated with a reduced risk of death or readmission in the following 30 days. Due to the possibility of unmeasured confounding in this observational study, experimental studies are needed to confirm this finding.

COMPARING MEDICAID AND MARKETPLACE COVERAGE: EFFECTS ON HEALTH CARE UTILIZATION, OUT-OF-POCKET SPENDING, AND COSTS

Heidi Allen³; Sarah Gordon⁴; Dennis Lee⁵; Benjamin D. Sommers^{1, 2}.

¹Harvard School of Public Health, Brookline, MA; ²Brigham & Women's Hospital, Boston, MA; ³Columbia University, New York, NY; ⁴Brown University, Providence, RI; ⁵Harvard University, Jamaica Plain, MA. (Control ID #3185045)

BACKGROUND: After the 2018 election, several states appear poised to expand Medicaid under the Affordable Care Act. The Trump administration is encouraging states to prioritize expanding private insurance instead, and some states have proposed moving Medicaid beneficiaries to private coverage. In this context, understanding the tradeoffs between these coverage types is critical. We leverage a unique dataset from Colorado's Medicaid and Marketplace agencies to compare the effects of insurance type on coverage duration, utilization, and health care costs.

METHODS: Using income data provided at the time of application for Medicaid or Marketplace coverage, merged with Colorado's All Payer Claims Database from 2014, we examined utilization, out-of-pocket spending, and total costs using a regression discontinuity (RD) approach. Our sample contained non-pregnant individuals ages 19-64, with incomes between 75% and 400% of the Federal Poverty Level (FPL), enrolled in Medicaid or Marketplace coverage in 2014 (N=206,810). Comparing individuals just below versus just above the eligibility threshold of 138% of FPL, we assessed the impact of coverage type on these health-care related outcomes.

RESULTS: Our preliminary findings are threefold. First, income just below the Medicaid eligibility threshold led to 6.9 months of additional Medicaid coverage per year, while those just above the threshold experienced 6.3 months more of Marketplace coverage. Second, utilization patterns differed significantly. Those eligible for Medicaid were 3.4 percentage-points more likely to visit the Emergency Department (ED) each year (sample mean 24%) than those eligible for Marketplace coverage, but were 6.3 percentage-points less likely to have an outpatient visit (sample mean 60%). Medicaid also led to a 4 percentage-point decrease in the likelihood of a prescription fill (sample mean 58%). We found no statistically significant differences in hospitalization rates. Third, costs were significantly higher in Marketplace coverage, despite the slight reduction in months covered. Annual spending per person was \$707 higher in Marketplace coverage than Medicaid, representing a 35% increase compared to the sample mean (\$2034). After standardizing prices to Medicaid rates, costs were similar in the two groups, indicating that different prices (not volume) were responsible for the cost difference between the two coverage types. Out-of-pocket spending (not including premiums) was even more disparate. Marketplace beneficiaries spent \$105 more per person than Medicaid enrollees, more than a fourfold increase compared to the Medicaid average (\$25.50).

CONCLUSIONS: Medicaid results in higher coverage rates than Marketplace insurance, but less outpatient care and more ED care. However, Medicaid coverage is substantially less costly both to enrollees and to society. These results have important implications for policymakers considering alternative approaches to coverage expansion.

COMPARING THE NATIONAL COST-EFFECTIVENESS OF ALTERNATIVE DIABETES SCREENING STRATEGIES

Rahul Dadwani¹; Mohammed Reza Skandari³; Lawrence Phillips²; Mary Rhee²; Neda Laiteerapong¹. ¹University of Chicago, Chicago, IL; ²Emory University School of Medicine, Atlanta, GA; ³Imperial College of London, London, United Kingdom. (Control ID #3168022)

BACKGROUND: With the high costs of diabetes in the United States, it is important to identify cost-effective strategies for Diabetes Mellitus screening. Currently, the American Diabetes Association (ADA) recommends the use of two of the following four tests to screen for diabetes: fasting plasma glucose (FPG), glycated hemoglobin (HbA1c), oral glucose tolerance test (OGTT) or random plasma glucose (RPG) if symptoms of hyperglycemia are present. However, recent studies have suggested that RPG values at lower screening thresholds than recommended by the ADA, and the glucose challenge (GCT) that is currently utilized for gestational diabetes screening, can be used for Type 2 diabetes screening. To assess the utility of these tests, this study models a one-time universal diabetes screening of the U.S population using alternative screening strategies.

METHODS: Using a lifetime Markov Monte Carlo simulation model (US Type 2 Diabetes Policy Model), this study examined the cost-effectiveness of all 16 combinations of two of five possible tests [FPG (>125 mg/dl), HbA1c ($>6.4\%$), OGTT (>199 mg/dl), GCT (>160 mg/dl) and RPG (>120 mg/dl) values collected for clinical purposes besides diabetes screening (opportunistic screening)]. We estimated lifetime costs and quality adjusted life years (QALYs) for each combination of screening tests for a nationally-representative sample of U.S adults (National Health and Nutrition Examination Survey 2013-2014) at high risk of developing diabetes according to United States Preventative Services Task Force criteria.

RESULTS: There was no statistically significant difference in either lifetime costs or QALYs between any of the 16 screening strategies. Lifetime costs ranged from \$78,333 (FPG followed by HbA1c) to \$82,059 (RPG followed by GCT) per person screened. QALYs ranged from 19.6274 (OGTT followed by GCT) to 19.6287 (HbA1c followed by OGTT or FPG).

CONCLUSIONS: This study suggests that diabetes screening strategies that utilize opportunistic RPG values at a lower threshold (>120 mg/dl) than currently recommended by the ADA (>200 mg/dl and symptoms of hyperglycemia) or the GCT may be comparable in effectiveness to current screening modalities. This is important because RPG values may already be clinically available for certain patients and, thus, a more convenient initial diabetes screening tool compared to tests that require the provider to make a conscious decision to screen his or her patient. Future studies that model the effect of diabetes screening should examine the impact of early intensive glycemic control and the subsequent "legacy effect" of early diabetes diagnoses.

COMPARING THE PERFORMANCE OF SELF-REPORT MEDICATION ADHERENCE MEASURES AMONG PATIENTS WITH LIMITED LITERACY AND ENGLISH PROFICIENCY

Lauren Opsasnick; Scott Hur; Laura M. Curtis; Stephanie Batio; Guisselle Wismer; Michael S. Wolf. Northwestern University, Chicago, IL. (Control ID #3185776)

BACKGROUND: Recent debates have ensued with regard to the use of certain self-report measures of medication adherence. Despite valid criticisms concerning social desirability of patient self-report, concerns around the validity of such assessments among lower literate, and more limited English proficient adults have also been raised by health services researchers. We sought to examine the concordance of different types of available self-report, medication adherence tools, and compare their construct validity within a sample of these more vulnerable, at-risk patient populations.

METHODS: 314 English and Spanish-speaking patients with type 2 diabetes, ages 32-80 at baseline, were recruited from 11 primary care clinics across Chicago. The study population was 92% low health literate (measured by the Newest Vital Sign), and 54% of patients had limited English proficiency. At baseline, patients underwent a structured interview where they were administered a measure intentionally designed for lower literate audiences (Patient Medication Adherence Questionnaire, PMAQ), as well as the Morisky Scale, and a demonstrated proper use task based on the prescription sigs. At a 6 month follow-up interview, an objective assessment of adherence was performed via pill count for each of the patients' diabetes and hypertension medicines. Additionally, the proportion of days covered (PDC) was obtained for a subset of patients who used a partnering national retail pharmacy (Walgreens). For this analysis, agreement and Kappa statistics were calculated between the three self-report adherence measures. Logistic regressions were conducted to assess if the baseline self-report measures predicted PDC or pill count. Additionally, a generalized linear model was performed to measure the impact of self-report adherence on glycemic control (HbA1c).

RESULTS: Agreement between PMAQ and proper use was measured at 56% (Kappa=0.10), whereas agreement between PMAQ and Morisky was 17% and agreement between proper use and Morisky was 23% (Kappa= -0.15 & -0.03, respectively). In multivariable analyses modeling pill count adherence and controlling for relevant covariates, PMAQ was associated with significantly higher odds of pill count adherence (OR=2.8; 95% CI: 1.4, 5.7; p<0.01). Proper use and Morisky had no significant associations with pill count. Additionally, multivariable analyses examining HbA1c as the outcome showed that PMAQ was significantly associated with a decline in HbA1c ($= -0.68$; 95% CI: $-1.09, -0.24$; p<0.01). Again, proper use and Morisky had no significant associations with HbA1c. Further multivariate modeling of PDC adherence was conducted on the Walgreens sub-sample, but results were insignificant due to the small sample size.

CONCLUSIONS: In a primarily low literate patient population, the PMAQ performed well as a means to predict pill count adherence, as well as clinical outcomes such as HbA1c. Conversely, the Morisky scale and demonstrated proper use task were found to lack construct and predictive validity.

COMPARISON OF ELECTRONIC CONSULTATION RECOMMENDATIONS FROM A COLLECTIVE OF CLINICIANS VERSUS BOARD-CERTIFIED SPECIALISTS

Elaine C. Khoong¹; Sarah Nouri¹; Delphine Tuot²; Valy Fontil¹; Urmimala Sarkar¹. ¹University of California - San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA. (Control ID #3185062)

BACKGROUND: Electronic consultations (e-consults) have improved timely access to specialists, but adoption remains incomplete. In areas with inadequate number of specialists, primary care providers may have limited access to e-consults/in-person specialty consultations. Preliminary studies suggest that leveraging the collective intelligence (CI) of multiple clinicians, or the shared intelligence that emerges from collaboration, may provide similar benefits to e-consults. We assessed the accuracy and harm of CI recommendations vs. specialist recommendations in e-consult cases.

METHODS: We collected actual endocrinology, neurology, gynecology e-consult cases from a single, integrated healthcare system. Case information was placed on an electronic CI platform, where a board-certified specialist then responded. If cases had gold-standard recommendations (defined as recommendations agreed upon by both the e-consult and CI platform specialists), we then identified a CI by soliciting responses from non-specialty clinicians through the CI platform. The platform aggregated responses into a CI output, which ranked all recommendations. We analyzed the CI output after at least five clinicians responded. The primary outcome was accuracy of CI output against gold-standard recommendations. Accuracy was defined at four levels: focused (all gold-standard recommendations ranked highest); expanded (all gold-standard recommendations ranked high); partial (some gold-standard recommendations ranked high); or none. For the top ten recommendations in the CI output, we assessed as a binary outcome the potential for meaningful harm among non-gold standard recommendations. Two research team clinicians independently assessed accuracy and harm and reached agreement.

RESULTS: At total of 227 clinicians answered 33 cases (11 endocrine, 10 neurology, 12 gynecology). A median of 11 clinicians (interquartile range [IQR]: 8-15) responded to each case. Table 1 shows accuracy of the CI output. The number of potentially harmful recommendations per case was: endocrinology (median 1, IQR 1-3); neurology (median 2, IQR 1-2); gynecology (median 2, IQR 1-3).

CONCLUSIONS: The CI of multiple clinicians is not equivalent to board-certified specialist recommendations, but it can provide useful recommendations. Some CI recommendations have potential for harm, and clinicians should be wary of higher-risk diagnostic tests/therapies. Future research should address refining CI to safely meet gaps in specialist access.

| Level of Accuracy | Endocrine | Neurology | Gynecology |
|-------------------|--------------|--------------|--------------|
| Focused | 0 / 11 (0%) | 2 / 10 (20%) | 4 / 12 (33%) |
| Expanded | 2 / 11 (18%) | 1 / 10 (10%) | 4 / 12 (33%) |
| Partial | 3 / 11 (27%) | 4 / 10 (40%) | 2 / 12 (17%) |
| None | 6 / 11 (55%) | 3 / 10 (30%) | 2 / 12 (17%) |

Table 1: Accuracy of Collective Intelligence Recommendations vs Specialist Recommendations for Electronic Consultation Cases

CONCORDANCE OF BELIEFS ABOUT CHRONIC OBSTRUCTIVE PULMONARY DISEASE, HYPERTENSION, AND DIABETES AMONG PATIENTS WITH MULTIMORBIDITY

Grace McInerney¹; Rachel O'Conor²; Michael S. Wolf²; Juan P. Wisnivesky³; Alex Federman¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Northwestern University, Chicago, IL; ³Mount Sinai School of Medicine, New York, NY. (Control ID #3184189)

BACKGROUND: Beliefs about chronic obstructive pulmonary disease (COPD) and its treatments are important because they influence COPD medication adherence. Comorbidities are common among COPD patients, but it is unknown whether health and medication beliefs for COPD are associated with beliefs for comorbid chronic diseases. Identifying common belief patterns would potentially provide efficient targets for promoting better self-management behaviors for patients with multimorbidity.

METHODS: To test the association of COPD illness and medication beliefs with illness and medication beliefs specific to hypertension or diabetes in patients with multimorbidity, we performed a cross-sectional analysis of data collected from COPD patients with comorbid hypertension or diabetes. A sample of 282 adults ages 40 years and older with COPD were recruited from primary care practices in New York, NY, and Chicago, IL. Beliefs about COPD, hypertension, and diabetes were measured using the Brief Illness Perception Questionnaire (BIPQ), with wording adapted to each condition. Higher scores indicate a more threatening view of the illness. Beliefs about COPD, hypertension, or diabetes medications, were measured in two domains (necessity, concerns) using the 10-item Beliefs about Medicines Questionnaire (BMQ). Correlation coefficients were calculated for the associations of beliefs (COPD and hypertension, or COPD and diabetes).

RESULTS: The mean age was 68 (SD 9), 59% were female, 38% were black and 17% were Hispanic; 98% had hypertension and 35% had diabetes, and 33% had both comorbidities. Beliefs about illness threat were highly correlated for COPD and hypertension ($r=0.52$, $P<0.0001$), and COPD and diabetes ($r=0.45$, $P<0.0001$). The correlation was similarly high for COPD and hypertension medication concerns ($r=0.64$, $P <0.0001$), COPD and diabetes medication concerns ($r=0.61$, $P<0.0001$), and COPD and hypertension medication necessity beliefs ($r=0.56$, $P<0.0001$), but less so for COPD and diabetes medication necessity beliefs ($r=0.31$, $P=0.004$).

CONCLUSIONS: Patients with COPD and comorbid hypertension or diabetes have mostly consistent beliefs about their diseases and the medications used to treat them. This consistency may provide opportunities to utilize patients' illness perceptions and medication beliefs to find strategies that facilitate improved self-management of multiple chronic illnesses.

CONCURRENT USE OF SULFONYLUREAS AND INTERACTING ANTIMICROBIALS IN THE UNITED STATES: NAMCS 2006-2015

Scott J. Pilla; Nisa Maruthur. Johns Hopkins University, Baltimore, MD. (Control ID #3162727)

BACKGROUND: Hypoglycemia is the most common serious adverse effect of diabetes treatment and is associated with significant morbidity and mortality. Sulfonylureas, the most common oral diabetes treatment after metformin, have interactions with a number of antimicrobials which substantially increase the risk of hypoglycemia when prescribed together. In this study, we provide the first nationally representative estimates of the concurrent use of sulfonylureas and interacting antimicrobials, and the indications for interacting antibiotic prescriptions.

METHODS: We used the 2006-2015 National Ambulatory Medical Care Survey (NAMCS), an annual sample of visits to office-based physicians, and National Hospital Ambulatory Medical Care Survey (NHAMCS), an annual sample of visits to hospital emergency departments, and outpatient departments through 2011. Together, these provide nationally representative estimates of U.S. physician visits. At each visit, physicians reported the patient's chief complaint and up to four additional reasons for the visit, as well as the medications ordered, supplied, administered, or continued. This study included visits for adults aged 18 years or older with concurrent use of a sulfonylurea and antimicrobial (excluding topical therapies). The primary outcome was use of antimicrobials interacting with sulfonylureas: clarithromycin, fluconazole, fluoroquinolones, metronidazole, or sulfamethoxazole-trimethoprim. We also examined whether the

reason for visit included diagnoses for which antibiotics (i.e. excluding antifungals) are almost always indicated (Tier 1), sometimes indicated (Tier 2), or not clearly indicated (Tier 3) using the algorithm developed by Fleming-Dutra et al. (JAMA 315(17): 1864-1873, 2016). Results are national estimates of patient visits (presented as the yearly average) or proportions.

RESULTS: Between 2006-2015, there were 2.6 million yearly visits (95% CI 2.2-3.0) for patients using sulfonylureas and antimicrobials, of which interacting antimicrobials were used in 38.9% (95% CI, 32.9-45.2) or 1.0 million visits (95% CI 0.8-1.2). Most visits with use of interacting antimicrobials occurred in ambulatory care offices (0.9 million, 95% CI 0.7-1.2); a minority occurred in other care settings. The most commonly used interacting antimicrobials were fluoroquinolones (60.3% of interacting antimicrobials, 95% CI 51.3-68.7) and sulfamethoxazole-trimethoprim (20.9%, 95% CI 14.8-28.7). Among visits using interacting antibiotics, 69.0% (95% CI 55.1-80.1) had no appropriate indication for antibiotic use (Tier 3); 9.1% (95% CI 6.0-13.7) and 21.9% (95% CI 11.3-38.2) had Tier 1 and Tier 2 indications, respectively. The most common Tier 1 indication was urinary tract infection (6.8% of interacting antibiotic visits, 95% CI 4.3-10.4).

CONCLUSIONS: Concurrent use of sulfonylureas and interacting antimicrobials is common in U.S. ambulatory practice and likely contributes to hypoglycemic events. Reducing inappropriate antibiotic prescribing may help alleviate this problem.

CONSOLIDATION IN THE DIALYSIS INDUSTRY AFTER BUNDLED PAYMENT REFORM

Caroline Sloan^{1, 2}; Abby Hoffman^{1, 3}; Matthew Maciejewski^{2, 1}; Cynthia Coffman^{1, 2}; Linda L. Sanders¹; Richard Hirth⁴; Shou-Yih D. Lee⁴; Virginia Wang^{1, 2}. ¹Duke University, Durham, NC; ²Durham VA Medical Center, Durham, NC; ³University of North Carolina Gillings School of Global Public Health, Chapel Hill, NC; ⁴University of Michigan, Ann Arbor, MI. (Control ID #3183020)

BACKGROUND: Dialysis facilities currently treat almost 500,000 patients with end-stage renal disease (ESRD) and have experienced accelerating consolidation over the last two decades. By the late 2000s, two for-profit chains controlled over 70% of the dialysis market, leading to concerns about further market concentration. The impact of Medicare's 2011 prospective payment system (PPS) for dialysis on consolidation in the dialysis industry is largely unknown. We evaluate whether rates of acquisition among dialysis facilities that were independently-owned or affiliated with small chains were higher in the post-PPS period compared to the pre-PPS period.

METHODS: We conducted a retrospective cohort study of non-federal US outpatient dialysis facilities that were independently-owned or affiliated with small chains (<20 facilities) for at least one year between 2008 and 2013. These facilities were deemed to be at highest risk of acquisition by large dialysis organizations. We used data from the Center for Medicare and Medicaid Services, the US Renal Data System and the Area Health Resource File to evaluate facility and market characteristics before (2008-2010) and after (2011-2013) the PPS. The outcome of interest was change in dialysis facility ownership (i.e. acquisition) before and after implementation of the PPS. We used a generalized estimating equation with a logit link to examine the association between the PPS and facility acquisition, adjusting for dialysis facility and regional demographic characteristics.

RESULTS: Overall, 1686 dialysis facilities (27% of all facilities in the US) were at risk of acquisition for at least one year of the entire study period; 59% were independently-owned and 41% were affiliated with small chains. Almost a quarter of at-risk facilities (23%) were new to the dialysis market during the study period. The rate of acquisitions increased from 4% (66/1495 facilities) before PPS to 8% (106/1412

facilities) after PPS. After adjusting for all covariates, the odds of acquisition increased after the PPS was introduced (odds ratio 1.72, 95% confidence interval 1.24-2.39).

CONCLUSIONS: Medicare payment reform was associated with increased acquisition of independent and small chain-affiliated facilities by large chains, possibly because large dialysis organizations are better poised to bear the financial risk associated with the PPS. Consolidation in the dialysis industry may be acting as a buffer against reduced revenue and increased financial risk in the post-PPS era. As the number of non-chain-affiliated dialysis facilities has dwindled in recent years, two large dialysis organizations have gained an increasing amount of market power. Closer scrutiny and additional policy interventions are needed to ensure sufficient diversification and competition in the dialysis industry.

CONSUMER EXPERIENCES WITH PRIVATE HEALTH INSURANCE PROVIDER NETWORKS

Kelly A. Kyanko¹; Susan Busch². ¹NYU School of Medicine, New York, NY; ²Yale University, New Haven, CT. (Control ID #3181557)

BACKGROUND: Provider networks are an important tool for private health insurers to control costs and ensure quality care for their enrollees. However, provider networks have been criticized for inaccurate directories, limited or narrow choice of providers that omit highly rated "star" hospitals and may lead to undesired or surprise out-of-network care, and disruption of continuity of care if a provider leaves the network or a patient changes plans. We conducted a nationally representative survey to examine consumer experiences and preferences with provider networks in private health insurance plans.

METHODS: Internet survey conducted in 2018 with participants in the GfK KnowledgePanel®, a probability-based online research panel designed to be representative of the U.S. population. The sample included 2,059 English-speaking US adults aged 18 to 64 years enrolled in private health insurance with a provider network and used an outpatient health care provider in the last year.

RESULTS: 74% agreed that their insurer had made enough in-network providers available. A significantly greater proportion of respondents rated protection from inpatient surprise bills as extremely important or very important from their plan as compared to inclusion of top rated "star" hospitals in the plan network (77% versus 59%, p<0.01). Among those with a choice of plan, 60% of respondents tried to determine if a specific provider was in-network before choosing a plan, and just over half (57%) reported that the result of the search affected their choice of plan. Of the 46% who used the provider directory once enrolled in the plan, 36% reported a problem either with inaccurate provider contact information or with a listed provider not actually taking their insurance or not taking new patients. Among the 16% who had a provider leave their network, 62-66% had their relationship with the provider disrupted and switched to new provider. Another 10-12% simply stopped treatment.

CONCLUSIONS: Consumers in private insurance plans report satisfaction with the breadth of their provider networks, however problems remain in the accuracy of provider directories and disruption in care from provider turnover. More respondents rated protection from surprise inpatient out-of-network bills as an important plan attribute compared to inclusion of top rated hospitals in the network. Insurers may consider in their product design strong consumer preferences for protections from surprise out-of-network bills and the inclusion of a specific provider in the network in their choice of a plan. In addition to monitoring network adequacy and accuracy of provider directories, additional policy efforts may be needed to ensure and continuity of care due to providers leaving a network. Addressing these provider network issues can preserve their function as a cost saving tool without compromising access and the consumer experience.

CONTEXTUAL AMBIGUITIES IN THE INTERPRETATION OF CODE STATUS ORDERS: AN ACTIONABLE TARGET FOR IMPROVING HOSPITAL CODE STATUS POLICIES

Jason N. Batten¹; Jacob A. Blythe¹; Sarah Wieten¹; Stephanie M. Harman¹; Miriam P. Cotler⁵; Joshua B. Kayser³; Karin Porter-Williamson⁴; Elizabeth Dzeng²; David Magnus¹. ¹Stanford University, Stanford, CA; ²University of California, San Francisco, San Francisco, CA; ³University of Pennsylvania, Philadelphia, PA; ⁴University of Kansas, Kansas City, KS; ⁵California State University, Northridge, Northridge, CA. (Control ID #3186011)

BACKGROUND: Code status orders (e.g., Do-Not-Resuscitate) are designed to succinctly and accurately convey patient preferences for cardiopulmonary resuscitation and other life-sustaining treatments (LSTs). Hospitals have adopted differing code status policies that vary in the number of code status options provided, their definitions, and the institutional ordering process (e.g., design of forms and menus). We sought to explore the ramifications of these differences in policy design for communication among medical team members.

METHODS: We designed a multi-institutional mixed methods study, selecting seven institutions to achieve variation in geographic location (western, midwestern, and eastern United States), type of institution (community, government, academic), and code status policy (i.e., what code status options are available and how they are defined). At each institution, we reviewed code status policies and menus in the electronic health record and conducted 60-90 minute semistructured interviews with physicians. We purposively sampled physicians based on specialty (internal medicine, palliative care, and critical care) and training level (attending physicians and trainees), for a total of 30 interviews. Using techniques from grounded theory, we analyzed transcripts to explore challenges in interpreting the intended meaning of code status orders.

RESULTS: Whether or not a physician who interprets a code status order arrives at its intended meaning (i.e., the meaning of the physician who authored the order) depends on many contextual factors outside of the order itself. We inductively identified six such contextual factors, which often remain implicit and may not be known by the interpreting physician: (1) the author's judgment of the patient's overall condition, (2) the author's intention in not addressing a potentially relevant LST, (3) the location of the patient in the hospital, (4) the clinical indication(s) for which the author intended the order to apply, (5) the purpose of the institutional code status policy, and (6) the author's identity and training level. Institutional policies and ordering practices vary in whether these contextual factors are explicitly addressed, thus aiding or hindering physicians in correctly interpreting the intended meaning of a code status order.

CONCLUSIONS: Failure to arrive at the intended meaning of a code status order is a threat to patient autonomy and a likely source of harm to patients. The contextual ambiguities that underlie these failures may be amenable to intervention through the careful design of hospital code status policies and ordering practices.

CONTRACEPTION ACCESS THROUGH DIRECT TO CONSUMER TELEMEDICINE

Radhika Rastogi⁴; Michael B. Rothberg¹; Laura D. Lipold³; Mark N. Rood²; Kathryn A. Martinez¹. ¹Cleveland Clinic, Cleveland, OH; ²Cleveland Clinic Foundation, Chagrin Falls, OH; ³Cleveland Clinic, Beachwood, OH; ⁴Cleveland Clinic Lerner College of Medicine, Cleveland, OH. (Control ID #3184250)

BACKGROUND: Direct to consumer (DTC) telemedicine connects patients with physicians via mobile applications, generally serving as a substitute for urgent care. Access to care is an often-reported barrier to obtaining hormonal contraception. Because visits are virtual and insurance is not required, use of DTC telemedicine could expand access to contraceptives. The objective of this study was to characterize requests for and provision of

contraceptives in a large nationwide DTC telemedicine service.

METHODS: Data come from the AmericanWell DTC telemedicine platform and includes encounters conducted between July 2016 and July 2018. Patients accessing the telemedicine system provided gender, age and insurance information, if applicable (out-of-pocket visits cost \$59). Via free-text field, patients stated their reason for accessing care. Two independent reviewers categorized patient-reported call reason based on keywords (e.g. "birth control," "refill," etc.), and also recorded if the patient cited problems with access to care for contraception. Prescriptions were determined via National Drug Codes associated with encounters, defined as drugs designated as contraceptives by the Food and Drug Administration. Promotional coupons for free or reduced cost visits on the platform are sometimes available. Whether a patient used a coupon for the visit was assessed. We described patients requesting and/or receiving contraception on the telemedicine platform in terms of patient-reported reason for accessing care, insurance information, and coupon use.

RESULTS: Of 159,033 telemedicine encounters with female patients during the study period, 652 reported their call reason was related to contraception and 718 received contraception. The mean age was 29 years (Standard Deviation=7.2). Of those with a contraception-related call reason, 78% received contraception. Based on the patient-reported call reason, 56% stated they were seeking a new birth control prescription and 33% were requesting refills. Six percent of patients reported problems with access to contraception, including insurance changes or difficulty seeing a provider. Patients requesting refills were more likely to receive contraceptives compared to those requesting new prescriptions (90% versus 79%, p<0.001). Of the 5% requesting emergency contraception, 89% received it. Patients requesting or receiving contraception were less likely to report insurance information than other telemedicine users (78% versus 85%, p<0.001) and were more likely to use a coupon for free or reduced-cost care (15% versus 8%, p<0.001).

CONCLUSIONS: Requests for contraception are relatively rare in DTC telemedicine, yet, of those seeking contraception, most received it. Greater use of coupons and lower insurance reporting suggests DTC telemedicine may be addressing access issues for some patients. While appropriateness is unknown, DTC telemedicine is likely a reasonable alternative to outpatient care for most women seeking either new contraceptive prescriptions or refills.

CONTRASTING OPINIONS BETWEEN PRIMARY CARE PROVIDERS AND HOSPITALISTS ON COMMUNICATIONS NEED-ED AT HOSPITAL DISCHARGE

Patrick Ryan^{1, 2}; Chi Zheng^{3, 2}; Anna Furniss⁴; John Rice⁴; Amy G. Huebschmann^{2, 4}; Elizabeth A. Bayliss^{5, 4}. ¹Denver Health and Hospital Authority, Denver, CO; ²University of Colorado School of Medicine, Aurora, CO; ³Denver Health, Denver, CO; ⁴Adult and Child Consortium for Outcomes Research and Delivery Science, Aurora, CO; ⁵Kaiser Permanente and University of Colorado, Denver, CO. (Control ID #3184748)

BACKGROUND: Clinical care has become less integrated since the advent of the hospitalist movement in the late 1990s, and is particularly prone to errors during transitions of care. With increased use of electronic health records (EHRs), there are now more options for primary care providers (PCPs) and hospitalists to communicate. The goal of this study was to assess PCP and hospitalist behaviors and attitudes regarding communication with one another at time of discharge.

METHODS: We performed a cross-sectional, web-based survey in June 2018 of PCPs and hospitalists, employed at two tertiary care health systems with shared EHRs between inpatient and outpatient settings. The survey contained 30 items addressing provider behaviors and attitudes towards communication methods and preferences, interprofessional care, transition of responsibility, and the value of collaboration between PCPs and hospitalists.

RESULTS: Of 439 potential participants, 191 (45%) responded; 34% were hospitalists. Only 5% of hospitalists, compared to 25% of PCPs, still participate in the opposite area of clinical care (outpatient vs. inpatient, respectively; $p < 0.01$). At least 70% of each group preferred electronic communication methods. Over 96% in both groups agreed that mutually developing a transition-of-care plan avoids errors in care delivery, and nearly 80% of each group agreed that interprofessional collaboration through scholarly work and interdepartmental meetings improves the quality of patient care and fosters collaboration. The majority of both PCPs and hospitalists (>80%) agreed that patients receiving interprofessional care from PCPs and hospitalists are more prepared for discharge than those who do not. Nearly all PCPs (99%) agreed that communicating the need for the PCP to take responsibility for inpatient test results upon discharge was important, compared to 89% of hospitalists ($p=0.03$). However, 47% of hospitalists felt that developing a transitions of care plan is excessively time consuming, compared to 16% of PCPs ($p < 0.01$). Only 17% of PCPs and 3% of hospitalists felt that patient care is adequately discussed between PCPs and hospitalists ($p=0.01$).

CONCLUSIONS: PCPs and hospitalists value interprofessional relationships and collaboration to provide high-quality care to patients. However, current practice structures make it difficult to find time to build these relationships, particularly for hospitalists. Given the preferred use of electronic messages to coordinate care between hospitalists and PCPs, EHR communications that specify care-transition needs may be a low-burden option to foster more collaboration between PCPs and hospitalists—however, the optimal content and delivery of care-transition communications require further study. Additionally, standardized agreements between PCP and hospitalist groups in their respective responsibilities in transitions-of-care may reduce errors during this critical time.

CONTROLLER MEDICATION USE AND EXACERBATIONS AMONG ADULTS WITH ASTHMA IN HIGH-DEDUCTIBLE HEALTH PLANS

Alison Galbraith^{1, 3}; Dennis Ross-Degnan¹; Fang Zhang¹; Xin Xu¹; Anna Sinaiko²; Jamie Wallace¹; Ann C. Wu³; James F. Wharam¹. ¹Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; ²Harvard TH Chan School of Public Health, Boston, MA; ³Boston Children's Hospital, Boston, MA. (Control ID #3185381)

BACKGROUND: High-deductible health plans (HDHPs) are increasingly common and require enrollees to pay annual individual deductibles of more than \$1,000 before the health plan will begin to pay for health care, often including medication costs. We sought to examine the impact of HDHP enrollment on asthma controller medication use and oral steroid bursts compared to enrollment in traditional health plans for adults with asthma.

METHODS: We selected adults aged 18–64 years who were enrolled in commercial coverage from a large national insurance carrier between 2004–2014 and had at least 12 months of enrollment in a traditional plan (baseline period) and 12 months of follow-up after either switching to a HDHP (intervention group) or staying in a traditional plan with low or no deductible (control group). Enrollees with a choice of plans were excluded to minimize bias due to selection. Our sample included all enrollees who had HEDIS-defined persistent asthma prior to the baseline year. We implemented a difference-in-difference (D-in-D) comparison of asthma care utilization between enrollees switching to a HDHP and controls staying in a traditional plan. We employed coarsened exact matching using baseline characteristics to select control groups. We analyzed changes in rates of 30-day fills of controller medications (inhaled corticosteroids [ICS], leukotriene inhibitors [LTI], or ICS-long-acting beta agonists [ICS-LABA]) and rate of asthma exacerbations (defined as oral steroid bursts) between the HDHP and control groups.

RESULTS: We identified 18,908 adults with persistent asthma who were switched to HDHPs, and 214,261 matched adult controls. Sixty-four percent of adults had no controller fills in the baseline year. Compared to

controls, enrollees in HDHPs had relative decreases in 30-day fill rates for any controller (D-in-D: -2.9% [95% CI -4.8% — -1.0%]) and for ICS-LABA (-3.1% [95% CI -5.8% — -0.5%]). There were no significant differences observed in rates of ICS or LTI fills, and no significant differences in rates of oral steroid bursts.

CONCLUSIONS: Regular utilization of asthma controller medications is low for adults with persistent asthma. HDHPs were associated with reduced use of controller medications overall, especially ICS-LABA. There were no differences in rates of asthma exacerbations as measured by oral steroid bursts. Regular use of important preventive asthma medications may be compromised in HDHPs, where patients must pay a greater (and increasingly often the full) amount out-of-pocket for medications for an expensive class of drugs, particularly ICS-LABA. Differences in controller fill rates between HDHP and traditional plan enrollees were modest, suggesting that HDHP enrollees are spending significantly more out-of-pocket on asthma medications each year, putting them at risk of financial burden.

COPING WITH COMMUNITY VIOLENCE: A MIXED METHODS STUDY OF ADULT RESPONSES TO CHRONIC TRAUMA

Tyrone A. Johnson; Nichole Smith; Madison R. Wilson; Monica E. Peek; Elizabeth L. Tung. University of Chicago, Chicago, IL. (Control ID #3184635)

BACKGROUND: Community violence continues to be a public health issue in many high-poverty, urban communities. Clinical strategies on providing care for violence-impacted patients are limited, as little research has examined how patients process and cope with violence. This mixed methods study aimed to characterize and quantify associations between violence exposure and common coping responses, including gun ownership.

METHODS: In 2017, we conducted, recorded, and transcribed focus groups and interviews with adults 35 years old ($N=51$) from 2 epicenters of violent crime in Chicago. Codes and themes were generated using grounded theory and the constant comparison method. In 2018, we additionally surveyed adult patients ($N=506$) using computer-assisted personal interviewing software. Participants were queried on coping strategies, using the Brief COPE normalized to a 100-point scale, as well as validated items about gun ownership. Lifetime violence exposure was measured using the Brief Trauma Questionnaire. We used generalized linear models to assess coping strategies as a function of violence exposure, controlling for age, gender, race/ethnicity, education, insurance, and employment. We also used identical model specifications to assess health behaviors as a function of positive or negative coping strategies.

RESULTS: Mean age was 60.2 ± 12.7 years. Participants were predominantly female (72%) and non-Hispanic black (76%). Two-thirds reported a prior exposure to community violence (62%), either as a direct victim (41%) or as an indirect witness, friend, or family member (49%). Some reported owning a gun (19%) or actively carrying a gun (12%), citing protection as the primary reason (77%). As one participant shared, "A lot more guys do carry a gun... for defense." Prior exposure to community violence was associated with 3.1 times higher odds of carrying any weapon (95% CI, 1.6–6.0) and 2.8 times higher odds of carrying a gun (95% CI, 1.3–6.1). A high level of stress due to violence was associated with a 29.3-point increase in implementing any coping strategy, positive or negative (95% CI, 22.9–35.8). However, participants reported implementing positive strategies (mean score 45.5) more often than negative strategies (mean 21.7, $p < .001$). For instance, exposure to community violence was significantly associated with increased coping by distraction (8.8 points; 95% CI, 1.7–15.9); one respondent explained the need to "plan fun... (to) try to lift your spirits." Higher positive coping was associated with more days of physical activity (1.03 days; 95% CI, 0.03–2.04), but not more days of fresh fruit and vegetable consumption or medication adherence.

CONCLUSIONS: Exposure to community violence was associated with both positive and negative coping strategies, including gun ownership.

Understanding how patients cope with community violence may inform healthcare strategies and intervention targets in high-risk populations.

CORRELATION BETWEEN BILIRUBINEMIA AND ACUTE KIDNEY INJURY IN PATIENTS WITH CIRRHOsis

Adrienne Lenhart²; Patrick Brown¹; omar khan¹; Maryam Alimirah¹; Hafsa Abdulla¹; Reena Salgia¹; Junior Uzman¹. ¹Henry Ford Health System, Detroit, MI; ²Henry Ford Hospital, Detroit, MI. (Control ID #3182074)

BACKGROUND: Acute kidney injury (AKI) in the setting of cirrhosis is associated with significant morbidity. However, data is limited regarding the role that hyperbilirubinemia plays in renal injury. One proposed mechanism is direct renal tubular injury from bilirubin and bile salts, but this is not well elucidated. Using a tertiary care population, we aimed to evaluate whether serum bilirubin levels predict the likelihood of AKI in patients with cirrhosis, as well as predict the probability of renal recovery in this population.

METHODS: Hospitalized patients with cirrhosis, with and without AKI, were retrospectively identified from January 2012 - December 2015. AKI was defined per KDIGO criteria and classified into HRS type 1, HRS type 2, and/or acute tubular necrosis (ATN). Other etiologies of AKI were excluded. Data concerning patient demographics, MELD-Na score, peak total serum bilirubin during hospitalization, change in total serum bilirubin from baseline, peak serum creatinine (SCr) during hospitalization, change in SCr from baseline, and nadir estimated glomerular filtration rate (eGFR) were analyzed. In patients with AKI, renal recovery was evaluated after 6 months of follow up and was defined as a return of SCr towards baseline or a lack of dialysis dependence.

RESULTS: A total of 200 cirrhotic patients were included. The majority were Caucasian (70%), male (62%), and had alcoholic cirrhosis (61%) as the etiology of their liver disease. Of these, 57% had AKI, while 43% did not. The average peak total bilirubin was significantly higher in patients with AKI compared to patients without AKI (13.6 mg/dL vs. 5.0 mg/dL respectively; p<0.001). The change in bilirubin from baseline was significantly higher in patients with AKI compared to patients without AKI (8.7 mg/dL vs. 2.5 mg/dL respectively; p<0.001). Patients' peak bilirubin level also correlated with their peak SCr (p<0.001), change in SCr (p=0.004), and nadir eGFR (p=0.004) during hospitalization. There was no significant difference in peak bilirubin levels between HRS type 1, HRS type 2, and ATN. While peak bilirubin level was unable to predict the likelihood of renal recovery among patients with AKI, a lower MELD-Na score was predictive of renal recovery (p=0.015).

CONCLUSIONS: Higher bilirubin levels predicted both an increased likelihood of and severity of AKI, manifested as both higher SCr and lower nadir eGFR. Elevated bilirubin also correlated with the development of both HRS and ATN, suggesting that hyperbilirubinemia may play a role in the pathogenesis of AKI, irrespective of etiology. Measured bilirubin did not predict renal recovery in cirrhotic patients with AKI. Further data on the association between hyperbilirubinemia and AKI can guide clinicians to risk stratify and plan initiation of dialysis. Identification of the pathogenic mechanisms may also lead to directed therapy.

CORRELATION BETWEEN SELF-ESTEEM AND INTERNAL MEDICINE CLERKSHIP GRADES

Rebecca B. Forman¹; Monica Malviya¹; Masrur A. Khan¹; Keara English¹; William Southern²; Amanda Raff²; Tulay Aksoy³. ¹Albert Einstein College of Medicine, Bronx, NY; ²Montefiore, Bronx, NY; ³Montefiore Medical Center, Bronx, NY. (Control ID #3184122)

BACKGROUND: Medical student performance in clinical

clerkships is assessed in a variety of ways using both clinical evaluations and standardized exams. Studies have shown that the clinical score can be influenced by factors including gender, age, and personality characteristics such as agreeableness, neuroticism, and extraversion. There have been very few studies, however, investigating the effect of self-esteem on clerkship grades. Our study assessed the relationship between medical students' self-esteem and internal medicine clerkship grades.

METHODS: Over the course of two academic years, an optional survey including the Rosenberg Self-Esteem Scale (RSES) was sent to all medical students in the internal medicine clerkship at our institution. Their responses were recorded and associated with their internal medicine clerkship grades. The de-identified data was provided to the research team. This study was deemed exempt by the Einstein Institutional Review Board. RSES is composed of ten statements answered on a 4-point agree/disagree scale. Responses are graded out of 40, with scores below 15 indicating low self-esteem. The scale has been shown to have both internal validity and test-retest reliability, both in general and in the field of higher education specifically. Chi-squared analysis was performed to assess for correlation between self-esteem scores and clerkship grades. Regression analysis was also performed to investigate correlation between individual survey answers and clerkship grades.

RESULTS: 356 students were eligible to participate. 97 responded (27% response rate), and 94 provided information to allow linking to clerkship grades; the remaining 3 were assumed to have received a non-honors grade for the purpose of analysis. 51 (53%) of the respondents were female, 45 (46%) were male, and 1 (1%) identified as non-binary. The average age was 26.4 ± 2.6 . 56 (60%) received either a High Pass or a Pass, and 38 (40%) received Honors in the clerkship. 11 (11%) had a low self-esteem score, and 86 (89%) had a self-esteem score within the normal range. Of the people with low self-esteem, 8 (73%) received a non-honors grade, and 3 (27%) received honors. Of people with normal self-esteem, 51 (59%) received a non-honors grade, and 35 (41%) received honors. The Pearson chi-squared score was 0.74, with a p-value of 0.39. Further analysis was conducted on individual questions, with no p-values reaching significance.

CONCLUSIONS: No significant correlation was found between self-esteem and an honors grade in the internal medicine clerkship. While this may indicate that grades are not affected by self-esteem, the results are hampered by a low response rate and a relatively small number of students with low self-esteem. A study with a larger population is necessary to further investigate this question.

CORTICOSTEROID USE FOR ACUTE RESPIRATORY TRACT INFECTIONS IN DIRECT TO CONSUMER TELEMEDICINE

Evan L. Dvorin³; Michael B. Rothberg¹; Mark N. Rood²; Kathryn A. Martinez¹. ¹Cleveland Clinic, Cleveland, OH; ²Cleveland Clinic Foundation, Chagrin Falls, OH; ³Ochsner Medical Center, Jefferson, LA. (Control ID #3182928)

BACKGROUND: Systemic corticosteroids are not indicated for acute respiratory tract infections (ARTIs), but may provide some symptom improvement for sinusitis and pharyngitis. Research in the outpatient setting shows substantial variation in corticosteroid use for ARTIs by physician and region, with the highest use in the South. ARTIs are the most common diagnosis in direct to consumer (DTC) telemedicine, yet use of corticosteroids in this setting is unknown. The objective of this study was to characterize corticosteroid prescriptions for ARTIs in a large nationwide DTC telemedicine platform.

METHODS: Data for this study come from the AmericanWell DTC telemedicine platform. Encounters with patients 18 years and older were conducted by board-certified physicians between July 2016 and July 2018. ARTI diagnoses were identified based on ICD10 codes. Encounters resulting in an inhaler prescription or coded with an asthma and/or COPD diagnosis were excluded. Oral corticosteroid and/or antibiotic receipt was determined by National Drug Codes associated with each encounter. Patient and physician geographic location were categorized by U.S. Census region, based on state of residence. To ensure stability of estimates at the physician level, physicians with <10 RTI encounters were excluded. Mixed effects logistic regression was used to assess differences in the odds of corticosteroid prescription, accounting for clustering by physician and geographic region. Models included specific ARTI diagnosis, patient age and geographic region, and physician specialty and geographic region. The model also accounted for antibiotic receipt.

RESULTS: The sample included 96,152 ARTI visits with 472 physicians, the majority of whom (58%) were board certified in Family Medicine. Most encounters were for sinusitis (45%), followed by pharyngitis (12%). Overall, 11% of ARTI visits resulted in a corticosteroid prescription. Of those, 33% also received an antibiotic. The mean prescribing rate for individual physicians ranged from 0% (7% never prescribed a corticosteroid) to 63%. In the adjusted model, compared to ARTI encounters with Northeastern physicians, those with Southern physicians had higher odds of resulting in a corticosteroid prescription (OR:4.37;95%CI:2.75-6.93). Compared to visits with Family Medicine physicians, those with Internal Medicine physicians were more likely to result in a corticosteroid prescription (OR:3.89; 95%CI:3.17-4.78). Receipt of a corticosteroid was associated with lower odds of antibiotic receipt (OR: 0.29;95%CI:0.28-0.31).

CONCLUSIONS: Prescription of corticosteroids for ARTIs in DTC telemedicine varied widely by physician. Regional variation suggests that prescribing is driven by physician preference rather than patient demand. Some physicians appear to substitute corticosteroids for antibiotics, but given adverse effects of corticosteroids, this practice should be discouraged.

COST & UTILIZATION OUTCOMES FOR A TELEMEDICINE-BASED URGENT CARE CLINIC OFFERED TO EMPLOYEES AT A LARGE ACADEMIC MEDICAL CENTER

Krisda H. Chaiyachati^{1, 2}; Christopher K. Snider²; Nandita Mitra²; Ann Marie Huffenberger³; Bill Hanson^{2, 3}; Gregory Kruse³; Katy Mahraj^{2, 3}; Shivan Mehta^{2, 2}; David A. Asch^{1, 2}. ¹The University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA; ³University of Pennsylvania Health System, Philadelphia, PA. (Control ID #3185179)

BACKGROUND: Employers are increasingly turning to telemedicine services to address low acuity urgent care needs among their insured employees. These efforts aim to reduce costs, but their effectiveness is unknown. Since July 2017, Penn Medicine has offered a free telemedicine-based urgent care clinic (FirstCall) to all health system insured employees and adult dependents, an estimated 50,000 covered lives. FirstCall is staffed 24/7, 365 days per year by Penn Medicine nurse practitioners who conduct live-telemedicine appointments and coordinate follow-up care. We evaluate the impact of FirstCall on health care costs.

METHODS: This study is a retrospective claims-based analysis comparing per episode costs for employees using FirstCall with employees treated conventionally for the same diagnoses between July 2017 to September 2018. To account for selection bias, we conducted 1:3 nearest neighbor matching between FirstCall and

non-FirstCall encounters using propensity scoring based on the encounter diagnosis, season, and employee's gender, age, employee or beneficiary status, median income of employee's ZIP code, and Charlson Comorbidity Score. Once matched, an employee's future encounters were excluded from matching. We used a generalized linear regression model to estimate per episode cost differences incurred within 3 days adjusting for employees' prior costs and utilization. As sensitivity analyses, we repeated these measures within 7-day and 30-day time windows. To estimate whether FirstCall substituted for conventional care, rather than inducing unnecessary care, we compared encounter rates for respiratory tract infections (the top diagnosis at 39% of all visits) before and after FirstCall was available using an interrupted time series analysis.

RESULTS: Our cohort included 1,335 FirstCall and 3,965 matched non-FirstCall users. Each FirstCall encounter avoided an average of \$215 (\$161 to 269; p<0.001) due to fewer visits to conventional care settings such as outpatient clinics, urgent care centers, and emergency departments. Results were unchanged with extended time windows. Rates for respiratory tract infection visits did not increase after FirstCall was offered.

CONCLUSIONS: FirstCall visits resulted in significant per episode cost savings. FirstCall's operational costs are fixed, therefore FirstCall's per episode costs are volume sensitive (i.e., more visits, lower per episode costs). Based on these estimates, FirstCall is budget neutral for Penn Medicine when 13 or more visits occur per day. These favorable per episode costs might be undermined if FirstCall's convenience induced utilization for symptoms that otherwise would have been ignored. However, these concerns are not supported given similar utilization rates for respiratory tract infections before and after FirstCall. Telemedicine services may be financially promising for academic medical centers with employer-sponsored health plans who offer in-house telemedicine services and care coordination as an employee benefit.

COST COMPARISONS OF OPIOID USE DISORDER TREATMENT PATHWAYS

Marc Larochele¹; Omid Ameli²; Sarah E. Wakeman³; Christine Chaisson²; Jeffrey McPheeters²; Francisca Azocar⁴; Darshak Sanghavi²; William Crown². ¹Boston University School of Medicine and Boston Medical Center, Boston, MA; ²OptumLabs, Cambridge, MA; ³Massachusetts General Hospital, Charlestown, MA; ⁴Optum Behavioral Health, San Francisco, CA. (Control ID #3185417)

BACKGROUND: Nearly 3 million Americans have opioid use disorder (OUD). The relative cost of initial OUD treatment strategies is unknown. We aimed to compare total cost of care across common OUD treatment pathways in a large, nationally representative sample.

METHODS: We conducted a retrospective cohort analysis using the OptumLabs® Data Warehouse of de-identified claims for privately insured and Medicare Advantage enrollees in a large U.S. health plan. We included individuals 16 years with OUD and contiguous enrollment for three months before and after index OUD diagnosis date. We identified OUD as 1 inpatient or 2 outpatient claims for opioid dependence or 1 claims for opioid dependence/use/abuse plus experiencing an overdose, medication for opioid use disorder, detox, or injection-related infection. We examined treatments received in the 12 weeks after cohort entry and clustered subjects into one of six pathway designations: 1) no treatment, 2) inpatient detox/rehab with/without medication for OUD, 3) buprenorphine/methadone, 4) naltrexone, 5) only behavioral health inclusive of intensive outpatient (BH - intensive), and

6) only behavioral health including other types of services (BH - other). The primary outcome was total cost of care, based on paid claims, in the 90 days after cohort entry. We used generalized linear models adjusting for age, sex, race, insurance type, and baseline comorbidities.

RESULTS: We identified 42,232 individuals with OUD between 1/1/2015 and 9/30/2017. The most common treatment pathway was BH - other (52.7%), followed by buprenorphine/methadone (19.1%); 5.9% received no treatment (Table). Unadjusted mean 90 day costs were \$16,885 for those who received no OUD treatment. Compared with no treatment, adjusted cost ratios ranged from 0.53 (95% CI:0.50-0.56) for buprenorphine/methadone to 1.98 (95% CI:1.87-2.10) for detox/rehab (Table).

CONCLUSIONS: In this large cohort of individuals with OUD and commercial or Medicare Advantage insurance, receipt of buprenorphine/methadone was associated with lower total 90 day costs compared with no treatment or other treatment options. Improving access to buprenorphine and methadone as the initial treatment for OUD may decrease costs compared with inpatient or outpatient behavioral health approaches.

COST-EFFECTIVENESS OF AN ELECTRONIC HEALTH RECORD-BASED INTERVENTION TO PREVENT WEIGHT REGAIN

Cindy L. Bryce²; Heather Tomko²; Kathleen Mary McTigue²; Jonathan Arnold⁴; Gary Fischer²; Bethany Barone Gibbs²; Rachel Hess³; Kimberly Huber²; Laurey Simkin-Silverman²; Dana Tudorascu²; Molly Conroy¹. ¹University of Utah, Salt Lake, UT; ²University of Pittsburgh, Pittsburgh, PA; ³University of Utah, Salt Lake City, UT; ⁴University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3183039)

BACKGROUND: Maintaining intentional, healthy weight loss poses a major behavioral health challenge, yet it is key to preventing and managing weight-related diseases such as diabetes and heart disease. Few studies have compared alternative approaches for avoiding weight regain after intentional loss and evaluated their cost effectiveness.

METHODS: Maintaining Activity and Nutrition through Technology-Assisted Innovation in Primary Care (MAINTAIN-pc) was a randomized controlled trial of primary care patients (n=196) who had intentionally lost at least 5% of their body weight. It compared the impact of an EHR-based self-monitoring system, either alone (tracking-only) or with personalized coaching, on weight regain. Participants recorded weight, plus diet/exercise information (calories, fat grams, steps, other physical activity) over time. Using 24-month data for costs (coaching time, participant monitoring frequency) and outcomes (weight change, quality of life using SF-36 data), we developed a Markov model to assess the cost-effectiveness of coaching relative to tracking-only for avoiding weight regain. Other parameters (hourly wages) relied on publicly available data.

RESULTS: Frequent self-monitoring was associated with better weight outcomes, and the coached participants monitored more consistently than tracking-only participants. Both groups reported good quality of life regardless of weight, resulting in only small gains in quality-adjusted life-years (QALYs) with coaching. When used in the analyses, we initially defined the effectiveness measure as *percent weight regain* and calculated a base case incremental cost-effectiveness ratio (ICER) for coaching relative to tracking-only that was less than \$500 per percent weight regain avoided (societal perspective). For the reference case using QALYs, the ICERs were \$23,740 and \$4,940 per QALY gained from societal and health care system perspectives, respectively.

Results were robust in sensitivity analyses—the main driver of costs is not personnel time, but rather participant time devoted to consistent monitoring. This was varied widely in probabilistic sensitivity analyses, and coaching was found to be cost-effective in 58% of model iterations (societal perspective) and 64% of model iterations (health care system perspective), based on an acceptability threshold of \$100,000 per QALY gained.

CONCLUSIONS: Maintenance of intentional, healthy weight loss is essential for realizing long-term health benefits. Although only minimal differences in quality of life between the two groups were reported, more weight regain was seen in the tracking-only group. Modeling the projected outcomes for longer time horizons would help inform overall health benefits and economic costs resulting from maintenance of intentional weight loss. Deployment of technologies that reduce the time needed to monitor health behaviors could also be useful for improving the cost-effectiveness of the coaching intervention.

COST-EFFECTIVENESS OF USING FINANCIAL INCENTIVES TO IMPROVE GLYCEMIC CONTROL: RESULTS OF A PILOT RCT

Leonard E. Egede¹; Rebekah J. Walker¹; Clara E. Dismuke-Greer²; Heather Prigmore¹; Joni S. Williams¹; April Z. Dawson¹; Jennifer A. Campbell¹. ¹Medical College of Wisconsin, Milwaukee, WI; ²Medical University of South Carolina, Charleston, SC. (Control ID #3185393)

BACKGROUND: Behavioral economics research theorizes the utility of providing financial incentives to overcome a natural tendency to discount the consequences of poor health behaviors. Given the daily self-management required for good glycemic control, individuals with diabetes may benefit from use of financial incentives in an effort to promote regular activities that improve glycemic control. However, the cost of using financial incentives for the benefit of improved glycemic control has not been tested. The aim of this project was to determine the cost-effectiveness of three financial incentive structures in obtaining a 1% drop in HbA1c.

METHODS: 60 African Americans with type 2 diabetes were randomized to one of three financial incentive structures and followed for 3 months. Group 1 received a single incentive at 3 months for A1c reduction, group 2 received a two-part incentive for home testing of glucose and A1c reduction at 3 months and group 3 received a multiple component incentive for home testing, attendance of weekly telephone education classes and A1c reduction at 3 months. The primary clinical outcome was A1c reduction within each arm at 3 months, and cost for each arm was calculated based on the cost of the intervention, cost of primary care, ER, and other health care visits during the 3-month time frame, and cost of work days missed from illness. Incremental cost effectiveness ratios (ICER) were calculated based on the intervention cost for each arm to achieve a 1% drop in HbA1c and were bootstrapped with 1,000 replications.

RESULTS: Incentive structures led to significant reductions in A1c at 3 months with a mean reduction for group 1 = 1.25%, mean reduction for group 2 = 1.73%, and mean reduction for group 3 = 1.74. Mean per person costs for each group were calculated at \$3,765 for group 1, \$4,649 for group 2, and \$3,315 for group 3. The incremental cost effectiveness ratio to decrease A1c by 1% was \$1,100 for all three arms, however, bootstrapped standard errors differed with group 1 having twice the variation around the ICER coefficient as groups 2 and 3. ICERs were statistically significant for groups 2 and 3 ($p<0.001$) indicating they are cost effective interventions for achieving a 1% drop in HbA1c.

CONCLUSIONS: Given ICERs of prior diabetes interventions range from \$1,000-\$4,000, a cost of \$1,100 per 1% decrease in HbA1c is a promising intervention, suggesting costs incurred through financial incentive systems have long term cost savings in health for diabetes populations. Multi-component financial incentive structures seem to have less variation in the cost effectiveness, and result in larger over drops in HbA1c suggesting more frequent and smaller incentives may be more effective in initiating behavior change than larger but less frequent incentives.

COUNT YOUR PENNIES: COSTS OF MEDICAL RESIDENT DEVIATION FROM CLINICAL PRACTICE GUIDELINES IN USE OF TESTING ACROSS 3 UNANNOUNCED STANDARDIZED PATIENT CASES

Eli Cahan²; Kathleen Hanley²; Andrew B. Wallach¹; Barbara Porter²; Lisa Altshuler²; Sondra Zabar²; Colleen C. Gillespie². ¹Bellevue Hospital, New York, NY; ²NYU School of Medicine, New York, NY. (Control ID #3185399)

BACKGROUND: Diagnostic tests account directly for 5% of healthcare costs, but influence decisions constituting 70% of health spending. Only 5% of ordered labs are actually "high value," depending on clinical circumstances. Low-value tests, defined as not appropriate for a given clinical scenario, are ordered in one in five clinic visits. Up to \$750 billion is spent on these low-value tests, contributing to the estimated one-quarter to one-third of healthcare spending is on wasteful services. We sought to quantify test-specific low-value ordering behaviors in urban outpatient clinics across three standardized patient cases.

METHODS: Unannounced standardized patients (USPs - highly trained actors portraying patients with standardized case presentations) were introduced into medicine residents' primary care clinics in a large urban, safety net hospital over the past five years. The USPs simulated three common outpatient clinical scenarios: a "Well" visit, a visit with a chief complaint of "Fatigue," and a visit with a diagnosis of "Asthma." Diagnostic orders were extracted via retrospective chart review for these standardized visits. For each scenario, appropriateness of diagnostic testing was determined by reference to United States Preventative Services Task Force (USPSTF) and relevant specialty society clinical practice guidelines (CPGs). "Wasteful" (over-ordered) tests were defined as those not explicitly indicated for the given scenario. Costs were derived from GoodRx.com according to local ZIP codes.

RESULTS: The most commonly wasteful tests for the Asthma case were CBC (8% of 170 visits) and Chem-7 (6%), though the relative risk of over-ordering TSH was 3.8x that of other scenarios. The most commonly over-ordered tests for the Fatigue case were LFTs (14% of 148 visits) and HBV (5%), with LFTs ordered up to 15-fold more frequently than in other scenarios. The most commonly over-ordered tests for the Well case were BMP (35% of 124 visits), CBC (15%), LFTs (15%), and HBV (11%) ordered at rates up to 6.3x, 2.0x, 14.2x, and 7.4x higher than other scenarios. Finally, the average per patient excess costs were \$8.27 (+/- \$1.76), \$6.79 (+/- \$4.5), and \$23.5 (+/- \$9.34) for Asthma, Fatigue, and Well cases respectively.

CONCLUSIONS: Inappropriateness in test ordering patterns were observed through USP simulated cases. Certain tests (CBC, BMP, LFTs, and HBV) were more likely used wastefully across cases. Between cases, specific tests were ordered in an inappropriate manner (such as TSH for Asthma, LFTs for Fatigue, and BMP for Well visits). The per patient direct cost of low value testing rose above \$20 per visit for the Well visit, though the Fatigue case exhibited the most variation. Notably, this excludes downstream (indirect) costs inestimatable from standardized encounters alone. Knowledge of wasteful utilization patterns associated with specific clinical scenarios can guide interventions targeting appropriate use of testing.

CULTURE AND COGNITION? THE ASSOCIATION BETWEEN ACCULTURATION AND SELF-REPORTED MEMORY PROBLEMS AMONG MIDDLE-AGED AND OLDER LATINOS IN THE NATIONAL HEALTH AND EXAMINATION SURVEY (NHANES), 1999 TO 2014

Alejandra Casillas¹; Li-Jung Liang²; Stefanie D. Vassar²; Arleen F. Brown². ¹David Geffen School of Medicine @ UCLA, Los Angeles, CA; ²UCLA, Los Angeles, CA. (Control ID #3186113)

BACKGROUND: The *Immigrant Paradox* suggests that immigrant Latinos are "protected" from negative health outcomes, like cognitive decline, versus US-born and/or acculturated Latinos. However, eight waves from the Hispanic Established Populations for the Epidemiologic Study of the Elderly recently showed that older age at migration (i.e. less acculturated) was associated with higher risk for cognitive decline. Other studies suggest that the effects of acculturation on health vary between Latino ethnic groups (i.e. Mexican vs. non-Mexican/other Latino). We examined the association between a well-established acculturation scale and self-reported memory problems (a "warning sign" for cognitive decline) over multiple time periods among Latinos in a nationally representative sample.

METHODS: These analyses included 5038 NHANES participants 45 years, in four 4-year time periods, between 1999-2014, who reported their race/ethnicity as Latino/Hispanic and were further categorized as "Mexican" or "other Latino." The primary outcome was self-reported memory problems (yes vs. no). An acculturation score (0/lowest - 3/highest) was calculated by giving 1 point for each of these characteristics: being born in the United States, speaking predominantly English, and living in the United States 20 years. We used generalized linear regression models with appropriate sample weights accounting for unequal probabilities of selection, oversampling, and non-response to examine the association between acculturation and memory problems, across ethnicity and age groups.

RESULTS: There was no difference in memory problems between the two ethnic groups for both middle aged (age 45-64 years) and older Latinos (age 65 years). Acculturation scores were higher for the Mexican groups for both age groups, across all time periods. Linear regressions showed a significant negative association between acculturation score and memory problems in older Latinos in three of the four latter time periods (range of estimates: -0.56 to -0.28; p-values= 0.05). When examining older Latinos by Mexican vs. other Latinos, acculturation and self-reported memory problems remained negatively correlated in both ethnic groups.

CONCLUSIONS: We observed that acculturation scores were negatively associated with self-reported memory problems (higher score-> lower % memory problems) among older Latinos, suggesting that acculturation may be protective against one of the early "warning signs" for cognitive decline. This finding is counter to the traditional theory of the *Immigrant Paradox*, wherein acculturation is linked to worsened health outcomes. These results point to a need for more aggressive efforts to address cognitive decline among less acculturated, older Latinos. Finally, the effects of acculturation on self-reported memory problems may be related to factors such as education, socioeconomic status and other social determinants, and warrant further investigation.

CURRENT LANDSCAPE OF CENTRALIZED IIS-BASED REMINDER/RECALL TO IMPROVE IMMUNIZATION RATES FOR ADULT IMMUNIZATIONS

Dennis Gurfinkel¹; Laura P. Hurley^{2, 1}; Alison Saville¹; Brenda Beaty^{3, 1}; Heather Roth⁴; Amanda Dayton⁵; Alison Chi⁵; Allison Kempe^{1, 6}. ¹University of Colorado, Aurora, CO; ²Denver Health, Denver, CO; ³University of Colorado, Aurora, CO; ⁴Colorado Department of Public Health and Environment, Denver, CO; ⁵American Immunization Registry Association, Washington DC, DC; ⁶University of Colorado and Children's Hospital Colorado, Aurora, CO. (Control ID #3185546)

BACKGROUND: Adult immunization information is increasingly being uploaded into Immunization Information Systems (IIS) nationally; the National Vaccine Advisory Committee has called for adult immunization documentation in IIS as part of their Standards for Adult Immunization Practice. Centralized IIS-based Reminder/Recall (C-R/R) performed by an IIS to centrally send out reminders to individuals about needed immunizations has been successful at increasing childhood immunization rates and is a promising approach to increasing adult immunization rates. Little is known about IIS managers' experiences regarding C-R/R for adult vaccines and perceived barriers to its use and sustainability.

METHODS: The objective of this study is to describe among IIS managers: 1) IIS capabilities related to performing C-R/R, 2) previous C-R/R experience and future interest in conducting C-R/R for adult vaccines, and 3) perceived barriers to C-R/R use and sustainability. A survey was developed in collaboration with the American Immunization Registry Association (AIRA). Surveys were sent electronically to all IIS managers in the U.S. and territories via AIRA's member network in July 2018. Up to 6 email and phone call follow-ups to non-responders occurred across a two-month period. A \$25 gift card was offered to respondents.

RESULTS: Fifty-seven of 62 IIS managers (92%) responded to the survey. All but one IIS reported the capability of receiving adult immunization data from various immunization providers. For 24% (13/55) of IIS, immunization reporting from primary care practices and public health departments for adult immunizations is mandated. Eighty-three percent (45/54) of respondents reported they have the capability to identify eligible patients needing immunizations at a county level and 76% (41/54) at a zip-code level. Sixty-one percent (34/56) of IIS have ever conducted C-R/R. Of the 25 who responded, 9 (36%) had done C-R/R so far for adult vaccines. Thirty-four percent (19/56) reported they are "very likely" to conduct C-R/R in the next 6 months; 28% (7/25) for adult vaccines. The most commonly reported barriers to performing C-R/R were lack of staff (78%), competing demands (76%), and cost (63%). Lack of support from leadership was a minor barrier (7%).

CONCLUSIONS: Most IIS have the capabilities to perform C-R/R within a geographical area and contain adult vaccination data. The majority of IIS have at least tried C-R/R, although a minority for adult vaccines. Sustaining and expanding C-R/R may require further training from successful programs regarding best practices for efficient C-R/R methods in order to limit staff involvement and costs. Successful programs for adult C-R/R should be disseminated and replicated by other IIS.

DECLINING USE OF PRIMARY CARE AMONG COMMERCIAL INSURED ADULTS IN THE US, 2008-2016

Ishani Ganguli¹; Zhuo Shi²; Aarti Rao³; Kristin N. Ray⁴; Ateev Mehrotra². ¹Brigham and Women's Hospital, Chestnut Hill, MA; ²Harvard Medical School, Boston, MA; ³Icahn School of Medicine, New York, NY; ⁴University of Pittsburgh, Pittsburgh, PA. (Control ID #3183630)

BACKGROUND: Primary care is a key component of the healthcare system and U.S. healthcare reform efforts, yet per capita visit rates to primary care physicians (PCPs) are declining. Using national commercial claims data, we explored potential mechanisms underlying this decline.

METHODS: We examined 2008-2016 claims data for adults (18-64 years old) enrolled with a large commercial insurer for at least one month in a given year. We determined annual visit rates to physicians and advanced practitioners (APs) providing primary or specialty care and to alternative settings (telemedicine, urgent care, retail clinic, emergency department). We stratified results by member demographic and clinical characteristics, baseline county-level visit rates, and visit characteristics including primary diagnosis type. We estimated linear trends for each subgroup; two-sided p values were significant at <0.005 (given multiple testing) unless otherwise specified.

RESULTS: Over the 8-year-period, PCP visit rates declined by 26.2% (167.5 visits per 100 member-years in 2008, 123.6 in 2016). More

adults had no visits in 2016 (32.5% of adults) than in 2008 (25.6%). The PCP visit decline was driven by problem-based visits (-40.8 visits, 26.5% decline) while preventive visit rates increased (+6.4 visits, 42.7% increase). The decline was larger for visits addressing low-acuity conditions (-15.2 visits, 45.4% decline) than for those addressing chronic conditions (-11.4 visits, 29.2% decline; p=0.01) and larger in counties with higher PCP visit rates in 2008 (-43.7 visits, 11.5% decline in top quartile of counties vs. 3.1 visits, 1.3% increase in bottom quartile p=0.69). When examining member characteristics, we found larger decline among those living in a zip code with median income 0-200% of federal poverty level (FPL) (-45.9 visits, 26.4% decline vs -22.0 visits, 14.2% decline for >400% FPL). Among members with a medical claim in a given year, the decline was greater for those without a chronic condition (-23.3 visits, 4.9% decline vs. -14.8 visits, 1.7% decline for those with a chronic condition). Over this period, a greater share of PCP visits were subject to deductible (+11.7 visits, 140% increase), while mean, inflation-adjusted out-of-pocket costs increased by \$9.89 per visit (33.6% increase). We observed a rise in visit rates to other clinicians (APs, +9.6 visits; specialists, +4.1 visits p=0.98) and settings (+9.1 visits), though these increases did not fully offset the decrease in PCP visits.

CONCLUSIONS: The decline in PCP visit rates was only partly explained by greater use of alternative clinicians and settings. Declines were larger for healthy members, for low-acuity condition visits, and in regions with higher-baseline visit rates, suggesting some of the foregone visits may have been unneeded. The larger decline among low-income patients coupled with the rise in deductibles and out-of-pocket costs imply financial barriers deterring PCP visits. Further work is needed to explore mechanisms in other populations.

DEMENTIA IS AN INDEPENDENT RISK FACTOR FOR CARE FRAGMENTATION AMONG OLDER ADULTS

Sara Turbow¹; Mohammed K. Ali²; Nikkil Sudharsanan³. ¹Emory University School of Medicine, Atlanta, GA; ²Emory University Rollins School of Public Health, Atlanta, GA; ³Harvard T.H. Chan School of Public Health, Boston, MA. (Control ID #3178904)

BACKGROUND: Of the over 35 million hospital admissions annually in the United States, 5 million result in readmissions, and over 25% of readmissions occur at hospitals different from the one the patient was previously discharged from. These fragmented readmissions are associated with poor outcomes including a nearly two-fold higher risk for mortality and additional \$2000 in healthcare costs per admission. Patients with Alzheimer's Disease and related dementias (ADRD) are more likely to be readmitted, but it is unknown if these readmissions are more likely to be fragmented or if dementia is itself a risk factor for fragmented readmissions.

METHODS: We analyzed data from the 2014 National Readmissions Database. Our analysis included adults 65 years old with an ICD-9 diagnosis code for ADRD. We defined fragmentation of care as a readmission to a hospital different from the one the patient was previously discharged from. We limited our analysis to the first two admissions in 2014. We estimated and compared prevalence of care fragmentation among older adults with and without ADRD. We compared demographic and clinical characteristics of ADRD and non-ADRD patients using chi-squared and t-tests. We used multivariable logistic regression to examine the relationship between ADRD and interhospital care fragmentation, adjusted for demographic and clinical variables. We used SAS 9.4 (Cary, NC) for all data analysis.

RESULTS: There were a total of 1,050,660 patients aged 65 years with readmissions in 2014. Of those, 8.0% had a diagnosis of ADRD. The prevalence of fragmented readmissions was higher for individuals with ADRD than those without (26.3% v 23.0%, p<0.001) (Table 1). In unadjusted regression models, dementia was associated with 19% higher odds of fragmented readmissions (95% CI 1.17-1.21) that persisted after adjustment for clinical and socio-demographic variables (Table 1).

CONCLUSIONS: Older adults with ADRD, who are already at risk for poor outcomes post-hospitalization, are at higher risk for readmissions to nonindex hospitals compared to those without ADRD. Further research on the causes and effects of fragmented care for patients with ADRD is needed to reduce the health and economic burden for this important and growing patient population.

DEPRESSION SCREENING OF ADULT ASIAN PATIENTS IN AN URBAN SAFETY-NET PRIMARY CARE CLINIC

Jennifer Dong^{1,2}; Mamadou Bah³; Sarika Modi^{1,2}. ¹NYU Langone Health, New York, NY; ²Bellevue Hospital, New York, NY; ³Monroe College, New York, NY. (Control ID #3186002)

BACKGROUND: Depression and suicide rates among Asian Americans are high, making them the only racial group in New York City for whom suicide is one of the top ten causes of death. The underutilization of mental health services by Asians compared to other ethnic groups is a disparity likely attributed to the strong stigma around mental illness and poor self-recognition of depression. Universal depression screening in primary care has led to increased detection and treatment of depression in all patients. We sought to understand the prevalence of depression through completion of the Patient Health Questionnaire (PHQ2) screener among Asian primary care patients at a large, urban, tertiary safety-net medical center.

METHODS: In our cross-sectional study we analyzed a registry of patients who identified their race as "Asian" and visited our primary care clinic (Bellevue Hospital Adult Primary Care Clinic) from July through December 2016. Chart review was performed to assess the completion and response rates of the Patient Health Questionnaire (PHQ2) and determine prevalence of depression. When possible, we identified countries of origin for each patient.

RESULTS: We identified a total of 1105 Asian patients. Regions of origin included East Asia (27.7%), Indian Subcontinent (29.3%), Southeast Asia (25.2%). Countries most represented were China, Bangladesh, the Philippines, and Tibet. For 11% of patients, there was no documentation of country of origin. PHQ2 completion rates by country were comparable to our overall clinic screening rate of 64%: China 65.0%, Bangladesh 67.5%, Philippines 64.1%, Tibet 61.3%. The rates of positive PHQ2 scores were: China 6.4%, Bangladesh 7.3%, Philippines 4.9%, Tibet 7.4%, comparable to the national depression rate of 8%. For English-speakers compared to non-English speakers, the rates of PHQ2 completion varies: China 65.8% vs. 64.9%, Tibet 68.8% vs. 57.1%, Bangladesh 64.0% vs. 70.8%, Philippines 63.1% vs. 80.0%. Of the positive PHQ2 screens, 72.7% of the Chinese patients had PHQ9 scores 10 or higher, indicating moderate depression or worse, as did 92.3% of Bengali, 16% of Tibetan, and 60% of Filipino patients.

CONCLUSIONS: Disparities in mental health screening and treatment continue to affect the Asian immigrant population, in part driven by culture and language differences. In our large, safety-net primary care clinic, the completion rate for depression screens among Asians are similar to the clinic's overall monthly PHQ2 screening rate of 64%. This analysis indicates that Asian patients in our clinic who screen positive on the PHQ9 may have moderate to severe depression, consistent with the phenomenon that depression in Asians is often under-detected, and therefore undertreated. Further studies are needed to assess the role of culture and language on depression screening for each Asian sub-group. We are conducting further analysis to review the rates of depression diagnosis and treatment patterns in this population.

DERIVATION AND VALIDATION OF A RISK ASSESSMENT MODEL FOR DRUG-RESISTANT PATHOGENS IN COMMUNITY-ACQUIRED PNEUMONIA

Michael B. Rothberg¹; Pei-Chun Yu¹; Peter K. Lindenauer²; Sarah Haessler²; Peter Imrey¹. ¹Cleveland Clinic, Cleveland, OH; ²Baystate Medical Center, Springfield, MA. (Control ID #3186282)

BACKGROUND: Antibiotic resistance is a major concern for patients hospitalized with community-acquired pneumonia (CAP). Risk factors for organisms resistant to recommended CAP therapy are known, but there are few validated risk assessment models for identifying such patients. We derived a risk assessment model using a large sample of CAP patients with blood or respiratory cultures. We then validated our model and compared it to the Drug Resistance in Pneumonia (DRIP) score.

METHODS: This cross-sectional study assessed adult patients admitted with pneumonia from 2010-2015 to 168 US hospitals that provided administrative and microbiologic data to Premier, Inc. Patients were identified by a combination of ICD-9 codes, chest x-ray, and antibiotic treatment. We also required patients to have blood or respiratory cultures performed by hospital day 1. We used stepwise multiple logistic regression to screen potential predictors of infections resistant to CAP therapy (ceftriaxone/azithromycin or levofloxacin): sociodemographics (age, sex, race, marital status); admissions, antibiotics and drug resistance in the past year; comorbidities, and severity of illness. For parsimony, we culled predictors based on prevalence, odds ratio, and clinical and statistical judgment. We developed our models in an 80% derivation set, reserving a 20% simple random sample for model validation. We then compared our model's receiver operating curve characteristics in the validation set to those of the DRIP score.

RESULTS: The derivation set contained 110,087 patients, of whom 2985 (2.7%) had cultures that grew organisms resistant to CAP therapy. A 21-predictor stepwise model was reduced to a 14-predictor model. Factors associated with antibiotic resistance in the reduced model were previous admission to hospital or cultured organism resistant to CAP therapy in the past year; admission from a skilled nursing facility; pressure ulcer or wound care; low functional status; chronic pulmonary disease; paralysis; ICU admission; SOFA score; vasopressors; mechanical ventilation; and male sex. Alcohol abuse predicted lower risk of resistance. The model had a c-statistic of 0.70 in the derivation set. In the validation set the model's c-statistic was 0.69 vs. 0.61 for the DRIP score. Predicted probabilities across deciles of risk ranged from 1.5% to 8.5% and calibration was good.

CONCLUSIONS: A risk assessment model with 14 predictors had good calibration and moderate discrimination. It outperformed the DRIP score in the validation set. After further validation, the model could be used in clinical practice to identify patients who would benefit from empiric broad spectrum antibiotic coverage.

DESCRIBING THE CLINICAL APPROACH TO DIAGNOSIS AND TREATMENT OF PATIENTS WITH HYPOACTIVE SEXUAL DESIRE DISORDER

Sharon J. Parish¹; Zainab Shahpurwala²; Rahul Ravindranath²; Amod Athavale²; Nandini Hadker²; Michelle Lim-Watson³. ¹Weill Cornell Medical College, New York, NY; ²Trinity Partners, Waltham, MA; ³AMAG Pharmaceuticals, Inc., Waltham, MA. (Control ID #3184893)

BACKGROUND: Hypoactive sexual desire disorder (HSDD) is defined as persistent diminished or lack of sexual desire accompanied by distress and affects approximately 10% of US women aged 18-44 years. Despite the high prevalence of HSDD, there is a limited understanding of the condition among physicians. The aim of this study was to understand the clinical approach to diagnosis, treatment, and unmet needs of patients with HSDD.

METHODS: Data from 312 medical charts from 103 US board-certified obstetricians/gynecologists (OB/GYNs), psychiatrists, and primary care physicians, which included family and internal medicine physicians, were collected and analyzed using an IRB-approved case report form that mimicked a typical patient chart. Physicians also completed an IRB-approved web-based questionnaire. Physicians treated/managed 2 patients diagnosed with HSDD and 5 patients diagnosed with female sexual dysfunction (FSD) each month. Inclusion criteria for medical charts were females 18 years old who had been diagnosed with HSDD.

RESULTS: Among the 103 physicians, 41% were OB/GYNs, 18% were family medicine physicians, 14% were internal medicine physicians, and

28% were psychiatrists; 16% reported a subspecialty in sexual medicine. Most primarily practiced in an office-based setting (92%) and spent most of their time engaged in patient care. Physicians reported a high level of comfort diagnosing and treating HSDD and initiated conversations about overall sexual health approximately half of the time. Medical charts for premenopausal (57%) and postmenopausal patients (43%) were analyzed; their mean age was 45 years. The time to diagnosis from the first physician visit for HSDD symptoms was approximately 4 months. The Decreased Sexual Desire Screener (DSDS) was used in only 14% of the medical charts to diagnose HSDD, and the Female Sexual Function Index and Female Sexual Distress Scale-Revised were used in only 2-4% of the medical charts to assess sexual function. While 72% of physicians agreed that HSDD is a medical condition, 30-40% did not associate hallmark symptoms of HSDD with the condition. Additionally, challenges exist in their ability to distinguish the symptoms of HSDD from other comorbid conditions, including other sexual problems such as decreased libido (83%), anorgasmia (56%), and sexual aversion disorder (50%), which are frequently associated with HSDD. Physicians reported a high level of unmet need regarding efficacious treatments for HSDD and reported only moderate levels of satisfaction with currently utilized treatments for HSDD.

CONCLUSIONS: While physicians agree that HSDD is a medical condition, a gap remains in the timely and appropriate diagnosis of HSDD using validated tools such as the DSDS and in differentiating HSDD from other FSDs. Additionally, there are a lack of efficacious treatment options for the treatment of HSDD. More education is needed to help physicians better identify HSDD symptoms and appropriately diagnose the condition.

DESIGN OF A MULTIFACETED STRATEGY TO INCREASE UPTAKE OF THE USPSTF HYPERTENSION SCREENING RECOMMENDATIONS IN A PRIMARY CARE NETWORK: USING THE BEHAVIORAL CHANGE WHEEL FRAMEWORK TO MAP BARRIERS TO THEORY-INFORM INTERVENTION COMPONENTS.
Nathalie Moise¹; Erica Phillips²; Jacob Julian¹; Anusorn Thanataveerat¹; Carmela Alcantara³; Eileen Carter³; Joseph Schwartz¹; Siqin Ye¹; Andrea T. Duran¹; Daichi Shimbo¹; Ian M. Kronish¹. ¹Columbia University Medical Center, New York, NY; ²Weill Cornell Medical College, New York, NY; ³Columbia University, New York, NY. (Control ID #3185313)

BACKGROUND: The U.S. Preventive Services Task Force (USPSTF) now recommends out-of-office blood pressure (BP) testing to exclude white-coat hypertension prior to hypertension diagnosis. Despite improved availability and coverage of home and 24-hour ambulatory BP monitoring (HBPM, ABPM), both are infrequently used to confirm diagnoses. Few if any studies of interventions to increase the use of out-of-office BP testing exist. We describe a theory-informed process for developing an implementation strategy to improve the uptake of out-of-office testing for hypertension diagnosis.

METHODS: We used the Behavior Change Wheel framework, a multi-step process for mapping barriers to theory-informed behavior change techniques. First, a multi-disciplinary team (medicine, psychology, nursing) conducted geographically diverse provider focus groups (n=63) to explore barriers to provider referral for out-of-office testing. Second, the team used content analysis to categorize barriers according to capability, opportunity, and/or motivation constructs (COM-B model). Third, the team independently mapped COM-B barriers to corresponding intervention functions (i.e., a list of 9 broad categories of ways an intervention can change behavior, e.g., education), and behavioral change techniques (i.e., a standardized language for describing the active ingredients in behavior change interventions). Lastly, the team conducted key informant interviews (n=12) with practice administrators, medical directors, providers, medical assistants, financial advisors, and nursing staff to refine and finalize intervention components.

RESULTS: Top ranked provider barriers to completing out-of-office BP testing included: lack of knowledge about the guideline (capability); limited

time to instruct patients about HBPM, costs of HBP devices, and challenges with accessing ABPM testing (opportunity); and concerns about ability to get patients to successfully and accurately complete tests and whether benefits of testing outweigh costs (motivation). We determined that the most feasible, effective behavioral change techniques would include delivering information about the consequences of out-of-office testing, demonstration/instruction on how to perform out-of-office HBPM and ABPM testing, feedback on completion rates of out-of-office testing, and adding objects to the environments/prompts and cues via a computerized clinical decision support (CDS) tool along with a culturally-tailored, locally accessible ABPM testing service.

CONCLUSIONS: In theory, a multicomponent implementation strategy of provider education, reminders, and decision support coupled with an ABPM testing service would be needed to implement out-of-office BP testing for the diagnosis of hypertension. We are currently testing the effect of our locally-adapted intervention on the change in the proportion of eligible patients who complete out-of-office BP testing in a 1:1 cluster randomized trial across 8 socioeconomically diverse clinics.

DESIGN THINKING TO IMPROVE PATIENT EXPERIENCE

Erin M. Rainosek¹; Erika Bowen¹; Thomas Pederson¹; Musarrat Nahid¹; Temple Ratcliffe³; Luci Leykum². ¹UT Health San Antonio, San Antonio, TX; ²STVHCS / UTHSCSA, San Antonio, TX; ³UTHSCSA, San Antonio, TX. (Control ID #3173061)

BACKGROUND: Hospitalization can be overwhelming for patients. Diagnostic uncertainty is common, and patients interact with many professionals who present information that may seem confusing. We bring a design thinking perspective to creating more patient-responsive hospital care, allowing their stories to drive the creation of a human-centered experience. Design thinking is about understanding needs and generating multiple ideas to create innovative, far reaching solutions. It focuses on how the system is experienced by the user. By using a rapid-cycle approach of obtaining input followed by ideation, prototyping, and testing, we offer a unique approach to improving experience and outcomes.

METHODS: We sought to explore patients' experiences of hospitalization from a design thinking perspective. As part of an ongoing collaborative care implementation, we interviewed patients, asking about their needs, communication, family involvement, and understanding of care plan. Patients were identified by a case manager based on cognitive function, acuity of illness, and English fluency. Interviews were recorded and transcribed. We adopted the design thinking method from IDEO, an international design firm, and coded interviews for unmet expectations, workarounds, tensions, problems, and needs. We aggregated responses with similar content into themes that allow us to identify opportunities for innovation.

RESULTS: We utilized interviews of 45 patients conducted over 3 months. Transcripts were coded by two members of the research teams, who had 74% agreement. Disagreements were resolved by consensus. Unmet expectations included patients' perception that information was not explained, or their expectation that physicians have answers to all of their questions, not recognizing that there might be diagnostic or treatment uncertainty. A key problem related to understanding important information versus day to day "noise." Patients used workarounds to better understand the care plan. An example includes self-checking consistency across the team to ensure accuracy in their care. Specific areas identified for improvement included understanding the care plan during admission, medicine reconciliation, involving family and caregivers, health literacy, coordination of services across specialties, and continuity of care transitions.

CONCLUSIONS: Design thinking offers a novel approach that focuses on understanding patients' experience as the basis for improving care delivery. Using patients' perspectives enables us to identify opportunities for innovation and ways to approach those opportunities that we would not otherwise discover by learning not just what patients say and do, but how they think and feel. In turn, we can understand their motivation for health in

terms of personal priorities rather than disease. These insights will allow us to better address their actual needs. Our work demonstrates the feasibility and utility of applying this framework to understanding hospital care from patients' perspectives.

DETERMINANTS OF PRIMARY HEALTHCARE UTILIZATION AMONG LGBT INDIVIDUALS IN HUDSON VALLEY REGION

Suman Pal; Nicole Zagelbaum; Anila Kumar; Alina Kifayat; Christopher Nabors; Rebecca Newman. Westchester Medical Center, Valhalla, NY. (Control ID #3184495)

BACKGROUND: The Lesbian, Gay, Bisexual and Transgender (LGBT) community represents a vulnerable population that has historically faced disparities in healthcare. Young adult members of the LGBT community are more likely to have mental health issues such as anxiety, depression and substance abuse, attempt suicide, be homeless, and have high rates of transmission of sexually transmitted infections including human immunodeficiency virus (HIV). They also face barriers to primary healthcare and preventive services due to fear of bias, social isolation, and fear of victimization. The United States department of health and human services Healthy People 2020 initiative aims to reduce disparities and improve LGBT health. In keeping with that goal, we aim to understand the facilitators and barriers to primary healthcare utilization for LGBT community in the Hudson Valley region.

METHODS: We utilized a cross-sectional study design using an anonymous online survey modified from the Gelberg-Anderson model of healthcare utilization among vulnerable populations. The survey was administered to a convenience sample of volunteers from the mailing list of the "LOFT" LGBT Community Services Center, a local LGBT organization, via email link to an online survey (SurveyMonkey ®). Data were analyzed using descriptive statistics. The study was approved by the New York Medical College Institutional Review Board (IRB).

RESULTS: In the first two weeks the survey was open, 26 persons responded. Of these, self-reported gender identities were: cisgender male (55%), cisgender female (33%), transgender (5%, FTM), transgender (5%, MTF) and 8 individuals who chose not to reveal their gender identity. With respect to sexual preferences, 20% identified as lesbian, 40% as gay, 12% as bisexual, 16% as asexual and 12% as heterosexual. While 87% of respondents believed that they should follow up with a primary care provider (PCP) regularly, 30% did not currently have a PCP. Of respondents who had a PCP, 35% were not comfortable discussing their sexual orientation and sexual well-being with that provider. In choosing an LGBT friendly PCP, the most important factors were prior positive experience with a provider and positive reference from friends or family. Access to mental health services was the second most important factor in choosing a LGBT friendly clinic. Other important factors were the use of appropriate gender and LGBT friendly language in verbal and written communication. Distance to LGBT friendly PCP and fear of discrimination were identified as key barriers to accessing healthcare by our respondents.

CONCLUSIONS: The results of this study indicate that factors related to LGBT community access to and comfort with primary care identified in prior published reports are also present in the Hudson Valley of New York. Data from this study will be utilized to make changes to the Patient Centered Medical Home (PCMH) at the Westchester Medical Center Adult Primary Care Center to better serve the local LGBT population.

DEVELOPING CHRONIC OPIOID USE AND OPIOID USE DISORDER FOLLOWING THE FIRST OPIOID PRESCRIPTION IN A POPULATION OF EMERGING ADULTS

J. Deanna Wilson^{1, 1}; Kaleb Abebe¹; Kevin Kraemer²; Elizabeth Miller³; David Kelley⁴; Julie M. Donohue⁵. ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh Medical Center, Pittsburgh, PA; ³Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; ⁴Pennsylvania

Department of Human Service, Harrisburgh, PA; ⁵University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA. (Control ID #3179164)

BACKGROUND: As one out of every five deaths among young adults is now a result of opioid-related morbidity and mortality, it is critical to understand prescription opioid use in adolescent and young adult (AYA) populations as it is the first exposure to opioids for many young people. We aim to characterize a population of AYA following the first opioid prescription to identify risk factors for chronic opioid use and time to opioid use disorder (OUD).

METHODS: We conducted a retrospective cohort analysis using data from Pennsylvania Medicaid enrollees from 2007-2016. We used National Drugs Codes in pharmacy claims to identify those age 10-21 years at time of the first opioid prescription. We included those with 6 months of continuous enrollment in Medicaid before and 12 months following the initial prescription. We used International Classification of Diseases, Ninth/Tenth Revision codes to define depression, anxiety, attention deficit disorder, and substance use disorders, including OUD, in the year following the initial prescription. Chronic opioid use was defined as receiving three or more opioid prescriptions. We used a mixed effects logistic regression model to estimate odds of chronic opioid use following the initial opioid prescription, and frailty time-to-event models to estimate time to first OUD diagnosis after accounting for county-level clustering using SAS. This study was deemed exempt by University of Pittsburgh IRB.

RESULTS: Among the 189,477 AYA who received an initial opioid prescription, the mean age at first prescription was 16.52 years (SD 2.80). Enrollees had high rates of comorbid mental illness with 24,637 (13%) diagnosed with depression, attention deficit hyperactivity disorder (N=25,681;14%), or anxiety (10,719;6%). By 12 months, approximately 14.3%(n=18,864) received two or more prescriptions following the initial opioid prescription and 6.2% (n=8,087) were given a diagnosis of OUD. Racial and ethnic minorities were less likely to both receive chronic opioids (OR 0.627 for Hispanic and OR 0.691 for Non-Hispanic Black) and develop OUD (HR 0.396 for Hispanic and 0.403 for Non-Hispanic Black). Females were more likely to receive chronic opioids (OR1.316) but less likely to be given a diagnosis of OUD than males (HR 0.887). Increases in duration of first opioid script from mean of 4.51 days and dosage from mean of 57.7 morphine milligram equivalents per day were associated with increased odds of chronic opioid use and also elevated risk of OUD.

CONCLUSIONS: Our findings demonstrate even short opioid prescriptions in a population of previously opioid-naïve young people are associated with high rates of chronic opioid prescribing. Over 1 in 20 AYA received an OUD diagnosis within 12 months of the first opioid prescription suggesting rapid escalation of opioid use and misuse in this population. Even short, low-dose opioid prescriptions seem to infer risk to vulnerable populations of emerging adults.

DEVELOPMENT AND EVALUATION OF A PREDIABETES DECISION AID ON PATIENT-CENTERED OUTCOMES

Matthew J. O'Brien¹; Kenzie A. Cameron¹; Namratha Kandula¹; Geoffrey C. Williams²; Angie Fagerlin³; Ronald T. Ackermann¹. ¹Northwestern University, Chicago, IL; ²University of Rochester, Rochester, NY; ³University of Utah, Salt Lake City, UT. (Control ID #3185982)

BACKGROUND: Eighty four million American adults have prediabetes, making diabetes prevention a public health priority. Despite the availability of two evidence-based treatments to prevent diabetes in this population—intensive lifestyle interventions (ILI) and metformin—neither is widely used. Patient-level barriers to initiating treatment include limited awareness or knowledge about prediabetes, inaccurate perceptions of their risk of developing diabetes, and low motivation to adopt treatment. Decision aids are the most widely studied method for communicating risk information and presenting treatment options, yet examples do not exist for prediabetes.

METHODS: With national stakeholders in diabetes prevention, our group developed a prediabetes decision aid and evaluated its impact on patient-centered outcomes. Inclusion criteria were age 18 years, prediabetes according to standard glycemic definitions, and BMI 25kg/m². Exclusion criteria were diabetes, dementia, and previous use of ILI or metformin. This pretest-posttest trial of 40 primary care patients tested whether exposure to the decision aid impacted the following 3 outcomes: 1) knowledge about diabetes prevention, 2) decisional conflict; and 3) intention to adopt ILI and/or metformin. Each of the outcomes was assessed with widely used, validated questionnaires. We used paired t-tests and McNemar's tests to examine pretest-posttest differences in the continuous and dichotomous study outcomes, respectively.

RESULTS: The study participants were 95% female and 68% Hispanic/Latino, with a mean age of 46.5 years. Exposure to the decision aid increased knowledge about diabetes risk, but the pre-post change was not significant. Mean decisional conflict scores were significantly decreased from pretest (31.0 ± 15.7) to posttest (20.9 ± 17.1), $p<0.001$. There were also significant reductions in all of the subscale scores for decisional conflict. The proportion of participants who intended to adopt ILI increased from 70% at baseline to 88% after exposure to the decision aid ($p=0.02$). There was no significant change in the proportion of participants who expressed intention to initiate metformin. The performance of the decision aid did not differ in subgroups defined by sex, language of administration (English vs. Spanish), or educational attainment (high school completion vs. lower).

CONCLUSIONS: This study demonstrates the feasibility and preliminary effectiveness of using a decision aid for diabetes prevention in primary care. Brief exposure to the decision aid resulted in modest improvements in knowledge about diabetes risk, significant reductions in decisional conflict, and significant increases in participants' intention to adopt ILI. Collectively, these findings suggest that our prediabetes decision aid is promising and may improve treatment decisions among patients with prediabetes in primary care.

DEVELOPMENT OF A NOVEL MEASURE OF TIMELY ACCESS TO PRIMARY CARE SERVICES

Matthew R. Augustine^{2, 1}; Adam J. Batten³; Karin M. Nelson^{3, 4}; Peter J. Kaboli^{6, 5}. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Department of Veterans Affairs, New York City, NY; ³Department of Veterans Affairs, Seattle, WA; ⁴University of Washington, Seattle, WA; ⁵Carver College, Iowa City, IA; ⁶Department of Veterans Affairs, Iowa City, IA. (Control ID #3169176)

BACKGROUND: Timeliness is a critical component of access and optimizing patient-centered care. Current objective measures of timely access to primary care (PC) may not account for patient-specific urgency or reflect modern scheduling practices. Our objective was to develop a novel measure for identifying clinic performance in fulfilling next-day and walk-in requests.

METHODS: We performed a retrospective, longitudinal analysis identifying clinic level success rates in fulfilling timely care requests within 48 hours from June 2014 to June 2017. We analyzed VA administrative data from 174 PC clinics located in 8 regional Veteran Integrated Service Networks. We defined a timely care request as any appointment type designated as walk-in or first next available. Successful fulfillment of timely care included a completed encounter within 48 hours and could occur in the same clinic with any PC provider, a different clinic within the same facility or regional network, a non-VA visit paid by VA, hospital admission, or via secure message or telehealth visit. Failure to provide timely care was determined if the patient was not seen within 48 hours, the appointment was cancelled by the clinic, or the appointment was fulfilled in the emergency department for conditions considered PC treatable as designated by a validated algorithm. We used Bayesian hierarchical regression to model the annual timely care success rate within each clinic, while controlling for age,

sex, race, rurality, and patient risk. For risk, we used Nosos, a co-morbidity score that predicts costs. In addition, we also tested two- and three-way interactions between rurality, patient risk, and time.

RESULTS: From 2014 to 2017, the number of timely care requests increased 17% from 240,191 to 280,874 with 32-40% of all patients requesting timely care. Of all timely care requests, 85-90% were successfully fulfilled: 98% by VA with 61-64% in PC, 31-33% in other VA clinics, and 3-4% in VA mental health clinics. Non-VA care and secure messaging fulfilled 2% and 1%, respectively. Of the 174 clinics, we identified a mean overall success rate of 87-88% with an upper bound of 95-97%. The distribution of success widened overtime with lower bound of the Bayesian credible interval decreasing from 72% to 64%. Fourteen clinics (11%) exhibited significant variability in their baseline timely care success rate and another 6 clinics had significantly decreasing success rates over time. All two and three-way interactions were not significant.

CONCLUSIONS: We developed a novel metric of timely care, which included patient perceived urgency, modern scheduling practices, and multiple care delivery modalities. Robust models identified a high level of timely care success across VA clinics and identified clinics struggling to deliver timely care. While further validation is needed, this measure offers a novel procedure to assess access while providing real-time, actionable information to clinical leadership.

DEVELOPMENT OF COMMUNICATION SKILLS ACROSS THE UME - GME CONTINUUM

Amanda Mari; Ruth Crowe; Kathleen Hanley; Deirdre Apicello; Norkila Sherpa; Lisa Altshuler; Sondra Zabar; Adina Kalet; Colleen C. Gillespie. NYU School of Medicine, New York, NY. (Control ID #3185402)

BACKGROUND: The core Entrustable Professional Activities medical school graduates should be able to perform on day 1 of residency provides a framework for readiness for residency. Communication skills are an essential foundation for these core EPAs and yet there have been few studies that describe communication competence across the UME-GME continuum. We report on our OSCE-based assessment of communication skills from the first few weeks of medical school to the first year of medicine residency.

METHODS: Assessment of communication is consistent in our OSCE program across UME and GME. Domains include Information Gathering (5 items), Relationship Development (6 items), and Patient Education (3 items) and these are assessed via a behaviorally anchored checklist (scores=% well done) that has strong reliability and validity evidence. In this study, we report on 3 multi-station OSCEs: the Introductory Clinical Experience (ICE) OSCE that occurs within the first weeks of medical school; the high-stakes, pass/fail Comprehensive Clinical Skills Examination (CCSE) OSCE that is fielded after clerkship year; and the Medicine Residency Program's PGY 1 OSCE. Across 3 classes of medical school (2014-2016) we have complete data for the 24 students who continued on in our Medicine Residency (and who provided consent to include their educational data in an IRB-approved registry). Analyses focus on differences in communication skills over time and between cohorts and the relationship between communication skills measured in medical school and those assessed in residency.

RESULTS: Communication scores show significant improvement through medical school (but not into residency) in Information gathering (ICE mean=56%; CCSE mean=76%; PGY1 mean=77%) ($F=11.54$, $p<.001$, ICE<CCSE) and in relationship development (ICE=59%; CCSE=78%; PGY1=74% ($F=10.68$, $p<.001$, ICE<CCSE). Mean patient education skills, however, increase significantly across all 3 time points (32% to 50% to 65%; $F=31.00$, $p<.001$). Patterns are similar across cohorts except that the Class of 2016 means increase from CCSE to PGY1. Regression analyses show that CCSE information gathering scores are more strongly associated with PGY performance than ICE scores (Std Beta=.32 vs .06), while for relationship development, it is the

ICE scores that are more strongly associated (Std Beta=.40 vs .24). ICE and CCSE patient education skills have associations with PGY1 skill of similar size (Std Beta=.30 and .28).

CONCLUSIONS: Findings, despite the small sample, suggest a clear developmental trajectory for communication skills development and that information gathering and patient education skills may be more influenced by medical school than relationship development. That communication skills seem to level out in PGY1 highlights need for reconsolidation as clinical complexity increases. Results can inform theory development on how communication skills develop and point to transitions where skills practice/feedback may be particularly important.

DIABETES PREVALENCE AND CONTROL IN THE UNINSURED OF THE TAMPA BAY AREA

Hadi Joud¹; Sabbir Mirza¹; Eslam Mohamed²; Hozaifa Tabbaa¹; Mouaz Tabbaa¹; Laurie Woodard¹; Rahul Mhaskar¹; Chighaf Bakour¹; Sayeef Mirza¹. ¹University of South Florida, Tampa, FL; ²Lake Erie College of Osteopathic Medicine, Bradenton, FL. (Control ID #3181454)

BACKGROUND: Diabetes is a common disease in many populations but places an especially heavy burden on the uninsured or underinsured, who are likely to utilize free healthcare services. These services, including free clinics, may provide patients with suboptimal treatment for diabetes and its many important comorbidities, such as hypertension and hyperlipidemia. The prevalence, management, and control of diabetes in uninsured or underinsured populations are not well studied and have only recently been examined in the Tampa Bay area. This study aims to characterize the prevalence and management of diabetes as well as predictors of good diabetes control in the uninsured of the Tampa Bay area.

METHODS: The study data was collected through a retrospective chart review of adult diabetic patients seen in nine different free clinics in the Tampa Bay area in 2016 and 2017. Sociodemographic variables, including race, ethnicity, age, and gender were collected along with chronic disease diagnoses, treatments, and relevant lab results. The data was analyzed in SAS and a logistic regression analysis was run to identify predictors of good control.

RESULTS: Out of 6815 patients seen in nine free clinics, 1323 patients were reported to be diabetic (19.41%). 787 of those (59.5%) had uncontrolled diabetes, defined by a HbA1C value of greater than 7%. The mean HbA1C for the study population was 7.98%. Demographically, the population was found to be mostly White (76.3%), Hispanic (52.4%), and female (54.1%). The mean BMI for diabetics was 32.3, with 59% of the population being obese and only 11.9% being of a normal weight. Compared to poorly controlled diabetics, those with good control were more likely to be female (59% vs. 56%), employed (58% vs. 50%), of normal weight (13.1% vs. 11.5%), and to have never smoked (67% vs. 62%). Logistic regression analysis showed that unemployment is a significant predictor of poor control (OR = 1.92, 95% CI 1.03, 3.60) after adjusting for age, gender, race, comorbidities, and BMI. When stratified by gender, unemployment is a significant predictor of poor control in males (OR = 4.13, 95% CI 1.36, 12.5), but not in females (OR = 1.40, 95% CI 0.62, 3.18).

CONCLUSIONS: Diabetes control is suboptimal in uninsured people visiting free clinics in the Tampa Bay Area, as evident by HbA1C levels. Unemployment appears to be a significant predictor of poor control in male diabetics, but not in females. Further research is needed to understand the mechanisms underlying this difference. Nutrition education initiatives may be beneficial in improving control of diabetes and decreasing the high rates of obesity by addressing the patients' lifestyles. Additionally, improving diabetes management programs at free clinics and equipping them with more resources may improve the quality of care and patient compliance.

DIAGNOSIS CODES VS. LABORATORY VALUES FOR IDENTIFICATION OF ACUTE KIDNEY INJURY

Amrit Vasdev^{1, 2}; Rachel Giblon¹; Joel A. Hickman¹; Arnar J. Jónsson³; Runolfur Palsson³; Kianoush Kashani¹; Bjorg Thorsteinsdottir^{1, 1}. ¹Mayo Clinic, Rochester, MN; ²University of Minnesota, Minneapolis, MN; ³Landspítali University Hospital, Reykjavik, Iceland. (Control ID #3185265)

BACKGROUND: Acute Kidney Injury (AKI) is a common syndrome especially in the context of multi-morbidity and can result in serious adverse outcome including mortality and chronic kidney disease (CKD). There have been concerns about the lack of sensitivity of billing codes in identifying this important complication. Therefore we sought to identify AKI episodes based on creatinine values in the electronic medical record and test its ability to detect AKI episodes as compared to ICD9 diagnosis code and chart review.

METHODS: Using a population based registry database from the Rochester Epidemiology Project, we identified patients >65 years of age who had a serum creatinine measured between 1996-2006. For each patient, each creatinine value was assessed for the presence of AKI using a previously validated macro, following, Kidney Disease Improving Global Outcome (KDIGO) guidelines, defined as an increase in serum creatinine 0.3 mg/dl in less than 48 hours or an increase from baseline of 0.3mg/dl using older creatinine values on file. We used AKI based on chart review as gold standard.

RESULTS: Of 29,494 patients identified there were 18,024 times ICD9 billing diagnosis code for Acute Kidney Injury was used in 6292 patients. ICD billing codes were only 55% sensitive compared to AKI diagnosis based on the laboratory based macro. Using chart review as the gold standard this algorithm had a positive predictive value of 64% and negative predictive value of 91%.

CONCLUSIONS: Diagnosis codes alone miss almost half of all AKI cases. Using an automated search based on the KDIGO guidelines shows high agreement with the previously validated code and significantly increases the sensitivity while maintaining high specificity. Our findings suggest that billing codes may be insufficiently sensitive to assess patient complexity across population and that one should be careful to draw firm conclusions, change policy or make practice recommendations solely based on big data based on billing diagnosis.

DIAGNOSTIC PITFALLS: OPERATIONALIZING A NEW PARADIGM TO UNDERSTAND AND PREVENT DIAGNOSTIC ERRORS

Harry Reyes Nieva^{1, 2}; Elise L. Ruan^{1, 3}; Mayya Volodarskaya^{1, 4}; Sumit Agarwal¹; Adam Wright^{1, 2}; Hardeep Singh⁵; Gordon D. Schiff^{1, 2}. ¹Brigham and Women's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA; ³Tufts University School of Medicine, Boston, MA; ⁴University of Chicago Pritzker School of Medicine, Chicago, IL; ⁵Michael E. DeBakey Veterans Affairs Medical Center and Baylor College of Medicine, Houston, TX. (Control ID #3184699)

BACKGROUND: Most diagnostic errors are rooted in cognitive and system failures with multifactorial origins. This complexity requires innovative approaches to better anticipate, detect and prevent them. We developed a new construct — diagnostic pitfalls — to account for both system and cognitive issues and create awareness of what can go wrong in diagnosis. We mined various data sources to uncover diagnostic errors and distilled disease-specific clinical pitfalls to analyze their types and patterns.

METHODS: We collected data from multiple sources to identify diagnostic error cases and delineated potential pitfalls, which we defined as clinical situations, patterns, or vulnerabilities related to errors leading to missed, delayed, or wrong diagnosis. Sources included a literature review, AHRQ Web M&M cases, institutional ambulatory M&Ms and risk management reports, focus groups with specialists, and primary care

malpractice closed claims for 5 years from 2 leading malpractice insurers in MA. To provide a framework for characterizing diagnostic errors, we used two previously published taxonomies Diagnosis Error Evaluation and Research (DEER) and Reliable Diagnosis Challenges (RDC). We performed an iterative thematic content analysis to derive both general and disease-specific diagnostic pitfalls. From qualitative review of these pitfalls, we created a taxonomy of generic types of pitfalls and then classified pitfalls from each case into one or more of these categories.

RESULTS: We identified a total of 549 diagnostic pitfalls. The most common diagnoses for which diagnostic errors and pitfalls were identified included cancer (n=186): colon (46) lung (43), prostate (34), breast (33), thyroid (7), melanoma (6), bladder (5), liver (5), Hodgkin's (4), renal (3); followed by other diagnoses: myocardial infarction (29), sepsis (16), stroke (16), pulmonary embolism (11), appendicitis (4), chronic heart failure (4), diabetes mellitus (4), disk herniation (3). Analysis of the top 10 diagnosis' pitfalls (n=241) included: failures in follow-up (28%), limitations of test or exam not appreciated (26%), disease A mistaken for disease B (24%), risk factors not adequately appreciated (16%), atypical presentation (15%), counter-diagnosis cues overlooked (10%), communication failures between primary care and specialists (7%), urgency not fully appreciated (3%), chronic disease presumed to account for new symptoms (2%), evolving symptoms not monitored (2%).

CONCLUSIONS: Diagnostic pitfalls is a new and useful construct to identify disease-specific pitfalls from diagnostic error cases. Analysis identified generic types of pitfalls and a taxonomy to categorize them, thus revealing the relative frequency of certain types of pitfalls. This work can serve as the basis for heightening situational awareness (e.g. interventions to detect and warn clinicians of pitfall situations) and building additional cognitive safety nets to prevent harm from falling into these traps.

DIASTOLIC DYSFUNCTION IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE A META-ANALYSIS

Angelina Zhyvotovska²; Denis Yusupov¹; Haroon Kamran^{2, 1}; Samy McFarlane²; Tarik Al-Bermani²; Samir T. Kumar²; Rishard Abdul².
¹SUNY Downstate Medical Center, Brooklyn, NY; ²SUNY Downstate, Brooklyn, NY. (Control ID #3159469)

BACKGROUND: Chronic obstructive pulmonary disease (COPD) is an important cause of morbidity and mortality around the world. Estimates show that in 2030 COPD will become the third leading cause of death worldwide. Additionally heart failure is a disease of great morbidity and mortality whose presence is estimated to increase by 46% from 2012 to 2030. Whether left ventricular diastolic dysfunction (LVDD) is a comorbidity in patients with COPD varies widely in literature. The association between DD and COPD is an important one to know given that dyspnea is a complaint shared between both illnesses. The objective of this meta-analysis was to determine if the prevalence of the diastolic dysfunction is increased in chronic obstructive pulmonary disease (COPD) patients as evidenced by echocardiographic parameters.

METHODS: We used a time-and-language-restricted search strategy to identify 4912 studies. 4905 were excluded, and we did a systematic review and meta-analysis of the seven remaining case control studies conducted to compare echocardiographic parameters to diagnose diastolic dysfunction in patients with COPD and controls.

RESULTS: A total of 7 studies with 764 subjects were included. The total of 4905 articles were excluded based on not meeting our inclusion criteria, case control studies performed after the year 2000. Duplicates were excluded. Eighteen studies meeting the inclusion criteria were reviewed in full; 9 articles were removed due to not clearly stating the findings, and two studies were removed because the results for their control groups were unclear. Therefore, a total of 7 studies were included (n=764). Our study found the prevalence of diastolic dysfunction was higher among COPD subjects versus control group patients (OR; 1.446,

C.I: 1.063-1.829, Z: 7.399; p: 0.000). The heterogeneity observed for the pooled analysis was Q-value; 17.855 df (Q); 5 P-value: 0.003, I-squared; 71.997; Tau2; 0.699, suggesting appropriate study selection and moderate heterogeneity. There were no differences in left ventricular ejection fraction.

CONCLUSIONS: Patients with COPD are more likely to have echocardiographic parameters of diastolic dysfunction. The diastolic dysfunction in this population, based on our data, is likely due to lung hyperinflation, chronic hypoxia, and ventricular interdependence: ventricular remodeling and deviation of the interventricular septum towards the left ventricle. Our study confirms the association between DD and COPD and sheds light that new treatment strategies that focus on preventing further cardiac dysfunction may improve mortality in COPD. Thus, more studies are needed to ascertain the effect of the treatment of COPD for the prevention of DD, a growing health burden.

DID THAT PCP PRESCRIBE THAT DRUG? CONCEPTUAL AND METHODOLOGICAL CHALLENGES IN DEFINING PRESCRIPTIONS INITIATED BY PCPS

Diana E. Norwich^{1, 2}; William L. Galanter^{3, 3}; Jennie B. Jarrett³; Maria Mirica²; Diane L. Seger^{2, 4}; Julie Fiskio²; Tewodros Eguale^{5, 2}; Alejandra Salazar²; John P. Cashy⁶; Jennifer A. Hale⁶; Jeffrey A. Linder⁷; Bruce Lambert⁸; Suzanne Falck⁹; Lynn A. Volk⁴; Gordon D. Schiff^{2, 10}. ¹Tufts University School of Medicine, Boston, MA; ²Brigham and Women's Hospital, Boston, MA; ³University of Illinois at Chicago, Chicago, IL; ⁴Partners HealthCare System, Somerville, MA; ⁵MCPHS University, Boston, MA; ⁶VA Pittsburgh Healthcare System, Pittsburgh, PA; ⁷Northwestern University Feinberg School of Medicine, Chicago, IL; ⁸Northwestern University, Evanston, IL; ⁹University of Illinois Hospital and Health Sciences System, Chicago, IL; ¹⁰Harvard Medical School, Boston, MA. (Control ID #3185583)

BACKGROUND: To understand the prescribing behaviors of primary care physicians it is necessary to identify their newly initiated prescriptions. While several studies invoke the concept of an initial prescription, definitions vary, and no standard criteria have been defined. As part of a multi-institutional study to understand variation in conservative prescribing practices, we explored and developed approaches to defining and identifying newly initiated prescriptions, attempting to account for various potential sources of error.

METHODS: We studied EMR prescription data from all PCPs (N=60) at University of Illinois at Chicago (UIC) and a sample (N=23) from Brigham and Women's Hospital (BWH) ordered in 2016-2017. After excluding refills, we identified the first patient-prescription occurrence during the study period. Data for the preceding two-year period was then reviewed to identify any prior prescriptions. We then sought to identify additional issues that could result in erroneously labelling a prescription as "new."

RESULTS: Of 65,114 prescriptions written by PCPs at BWH, 29,647 (46%) were identified as newly initiated, while 79,419/161,062 (49%) were newly initiated at UIC. Reviewing the data we identified three additional issues needing to be refined in the algorithm to accurately classify a new prescription: (i) excluding patient-reported prior medications, (ii) accounting for first-time visits, where pre-existing drugs may be misinterpreted as new, and (iii) how to handle drugs (e.g. selected antibiotics) with primarily acute indications that should be considered new even though their record had evidence of prior prescriptions. For issue (iii), a review of prescription data for 19 medications (12,808 total prescriptions) with both acute and chronic indications, showed that 7 were prescribed acutely >80% of the time at both institutions, suggesting that prescriptions for these drugs can generally be considered new, while

the remaining 12 may require specific indications-based rules for categorization as new vs. pre-existing.

CONCLUSIONS: This analysis confirms the importance of developing and adhering to a consistent, measurable, defensible, and reproducible definition of an initial prescription because nearly half of all PCPs' prescriptions in our dataset were not actually newly-initiated by the prescribing PCP. Using EMR rather than claims data both adds clinical richness and introduces methodological challenges (since longitudinal ordering and fill data is lacking) that must be addressed—most notably, accounting for patient-reported medications, accounting for first-time visits, and medications with both acute and chronic indications. Efforts to determine the percentage of prescriptions in these challenging categories is underway. Addressing these challenges is key not only for informing a definition of a newly-initiated prescription, but also for highlighting the data elements that must be accounted for to facilitate accurate analyses.

DID THE HOSPITAL READMISSION REDUCTION PROGRAM RESULT IN DELAYED READMISSIONS JUST AFTER 30 DAYS?

Joseph Martinez^{1, 2}; Ashwin Nathan^{3, 2}; Jay Giri^{3, 2}; Amol S. Navathe^{1, 2}. ¹University of Pennsylvania, Philadelphia, PA; ²Leonard Davis Institute, Philadelphia, PA; ³Hospital of the University of Pennsylvania, Philadelphia, PA. (Control ID #3183402)

BACKGROUND: The Hospital Readmission Reduction Program (HRRP) was enacted in March 2010 and imposed financial penalties beginning in October 2012 for hospitals with higher-than-expected 30-day readmissions for acute myocardial infarction (AMI), congestive heart failure (CHF) and pneumonia. The HRRP has been associated with reduced readmissions for these conditions, but recent evidence has also suggested an increase in mortality for heart failure and pneumonia as an unintended consequence. Because of strong hospital responses to the HRRP, we examined whether hospitals postponed readmissions around the 30-day threshold, resulting in a spike in "delayed" readmission just after 30 days.

METHODS: Hospital admissions for AMI, CHF, and pneumonia were identified between January 2007 and October 2015 using the Medicare Provider Analysis and Review (MedPAR) database, containing admissions for all fee-for-service Medicare enrollees. Stroke was studied as a falsification endpoint because it was not included in HRRP. As in prior literature, we divided the study period into three phases: the pre-HRRP phase (January 2007 to March 2009), the implementation phase (April 2009 to September 2012), and the penalty phase (October 2012 to October 2015). We used an interrupted time-series analysis to examine whether there was an increased probability of readmissions between days 31-35 compared to days 25-30. We estimated Poisson and Quasi-Poisson with slope and intercept changes and adjustments for seasonality by condition and compared the changes in slope for AMI, CHF, pneumonia and stroke in the three phases.

RESULTS: A total of 68,020,501 admissions were included in this analysis. For AMI, the slopes for readmissions between days 31 to 35 as compared to days 25 to 30 over time were -0.003, 0.001 and -0.0003 for the three phases, respectively. The change in slope between the pre-HRRP and penalty phase was 0.003 ($p=0.31$). For pneumonia, the slopes for readmissions between days 31 to 35 as compared to days 25 to 30 over time were 0.002, -0.0004 and 0.001 for the three phases, respectively. The change in slope between the pre-HRRP and penalty phase was -0.001 ($p=0.74$). For CHF, the slopes for readmissions between days 31 to 35 as compared to days 25 to 30 over time were 0.001, -0.0002 and -0.001 for the three phases, respectively. The change in slope between the pre-HRRP and penalty phase was -0.001 ($p=0.29$). For stroke, the changes in

slope between days 31 to 35 as compared to days 25 to 30 were 0.002, 0.0004 and -0.002 for the three phases, respectively. The change in slope between the pre-HRRP and penalty phase was -0.004 ($p=0.11$).

CONCLUSIONS: Using a national sample of Medicare enrollees, we found no association between the start of HRRP and higher likelihood of readmissions for AMI, CHF, or pneumonia just after 30 days. This suggests that hospitals did not differentially delay readmissions from just before to just after 30-days for AMI, CHF, pneumonia or stroke in response to HRRP.

DIFFERENCES IN ED DESTINATION OF EMS TRANSPORT OF CO-LOCATED PATIENTS BY RACE/ETHNICITY

Amresh D. Hanchate¹; Michael K. Paasche-Orlow²; William E. Baker²; Meng-Yun Lin³; Souvik Banerjee¹; James Feldman¹. ¹Boston University School of Medicine, Boston, MA; ²Boston University, Boston, MA; ³Boston Medical Center, Boston, MA. (Control ID #3176475)

BACKGROUND: National evidence indicates systematic differences in hospitals where racial/ethnic minorities receive care, with most care obtained in a small proportion of hospitals. As a large proportion of patients hospitalized for acute conditions arrive by emergency medical services (EMS), we examined for patterns in emergency department (ED) destination of EMS transported patients by race/ethnicity. To adjust for residential segregation by race/ethnicity, we used a national sample of Medicare enrollees purposively sampled to enable comparison of transport destination of patients from the same zip code.

METHODS: Using administrative data for a national sample of Medicare enrollees (2006-2012), we selected zip codes with a sizable count (>10) of Hispanic, (non-Hispanic) black and (non-Hispanic) white enrollees and obtained data on all ED visits using EMS. Identifying the most frequent (modal) ED destination for EMS-transported white patients from each zip code as the "reference ED" destination, we defined concordance with reference ED as the main outcome. We estimated differences in concordance rates by race/ethnicity, overall and for subgroups by demographics, clinical condition, socioeconomic status and proximity to multiple EDs. We used zip code level fixed effects to limit comparison of patients from same zip code. A secondary outcome was EMS transport to a safety-net ED, defined as the top quartile of hospitals by Medicaid patient share in each hospital referral region. We performed similar analysis of ED visits without using EMS.

RESULTS: In our study cohort of 864,750 enrollees from 4,175 selected zip codes, there were 458,701 ED visits using EMS. Overall 61.3% of white patients were transported to the reference ED; this rate was lower among black (-5.3%; 95% confidence interval [CI], -6.0% to -4.6%) and Hispanic (-2.5%; 95% CI, -3.2% to -1.7%) patients. A similar pattern was found among subgroup of high-risk patients with acute myocardial infarction, heart failure, pneumonia, stroke, sepsis and GI bleed. Concordance rates were lower in areas with multiple nearby EDs; in the largest 16 US cities, concordance rate was 46.1% among whites, and lower among blacks (-9.3%; 95% CI, -10.9% to -7.7%) and Hispanics (-2.7%; 95% CI, -4.5% to -0.8%). As reference ED is usually the most proximate ED, bypassing of nearest ED was common among all race/ethnic groups. In all areas, black and Hispanic EMS patients were more likely to be transported to a safety-net ED compared to co-resident white patients. Parallel analyses of concordance rates of ED visits without using EMS indicated significantly lower rates relative to those for EMS transported ED visits.

CONCLUSIONS: We found variation by race/ethnicity in destination ED for EMS transport patients, with black and Hispanic patients more likely to be transported to a safety-net hospital relative to

whites. The extent to which these differences arise from factors other than proximity (e.g., patient preference) need to be examined.

DIFFERENCES IN NARRATIVE LANGUAGE IN EVALUATIONS OF MEDICAL STUDENTS BY THE GENDER AND UNDER-REPRESENTED MINORITY STATUS OF MEDICAL EDUCATORS

Alexandra E. Rojek¹; Joanne W. Yim¹; Sarah Lisker¹; Rebekah Gardner²; Raman Khanna¹; Karen E. Hauer¹; Catherine R. Lucey¹; Urmimala Sarkar¹. ¹University of California, San Francisco, San Francisco, CA; ²Brown University, Providence, RI. (Control ID #3186008)

BACKGROUND: Prior studies have shown significant differences in narrative evaluations associated with the gender and under-represented minority (URM) status of medical students, even among students receiving the same grade. Limited qualitative studies in other educational settings suggest that male and female evaluators may assess students differently based on the student's gender. It remains poorly described, however, whether in medicine the gender and URM status of the evaluator influences the narrative text of evaluations.

METHODS: We set out to identify and enumerate text descriptors in medical student evaluations, particularly the differences in language depending on evaluator gender and URM status, and whether these differences persisted after adjustment for student gender and URM status. We collected clerkship evaluations from core clinical rotations at two medical schools, parsed the de-identified text of evaluations with a neural network algorithm, and employed natural language processing to quantify differences in the narrative text.

RESULTS: There were 86,655 evaluations, 41,629 (48%) by male evaluators and 45,026 (52%) by female evaluators; 10,049 (12%) were by URM evaluators, and 70,799 (82%) were by non-URM evaluators. We found significant differences in how students were described depending on the gender and URM status of their evaluator, and a subset of these differences remained significant after adjustment for students' gender and URM status. Of 1,312 descriptors identified in all evaluations, the usage frequency of descriptors was significantly different by evaluator gender for 152 (11.5%) words, and by evaluator URM status the usage frequency differed significantly for 76 (5.7%) words. Of the 100 most commonly used descriptors, 64 were used significantly differently by evaluator gender, and 45 were used significantly differently by evaluator URM status. For example, female evaluators used "wonderful" more than men ($p<0.001$), while men used the term "superb" more often ($p<0.001$). URM evaluators used the term "mature" ($p<0.001$) more often, and non-URM evaluators the term "impressive" ($p<0.001$). When adjusting for student URM status, there were minimal differences among URM students, although non-URM students were described differently depending on URM status of their evaluator.

CONCLUSIONS: While many of the descriptors used are shared, we find that there were preferred vocabularies used by male and female evaluators tied to evaluators' genders regardless of students' gender, and subsets of preferred vocabularies when segmenting by students' gender. When interrogating evaluators' and students' URM statuses together, we find few differences in how evaluators describe URM students, but preferred sets of descriptors for how evaluators describe non-URM students. These findings raise concern for an additional set of biases in narrative evaluation of students that is not directly related to students' clinical performance and may have implications in their career paths.

DIFFERENCES IN PRIMARY CARE ACCESS, PROVIDER TRUST, AND DISCLOSURE OF SAME-SEX BEHAVIORS TO PRIMARY CARE PROVIDERS AMONG MEN WHO HAVE SEX WITH MEN IN THE UNITED STATES

Christopher B. Stults³; Christian Grov²; Kathryn Anastos¹; Elizabeth A. Kelvin²; Viraj V. Patel¹. ¹Montefiore Medical Center/Albert Einstein College of Medicine, New York, NY; ²City University of New York, New York, NY; ³Baruch College, New York, NY. (Control ID #3186080)

BACKGROUND: Engaging in primary care is important to ensure appropriate healthcare. Men who have sex with men (MSM) may be less likely to access primary care and engage fully, but little is known about factors associated with primary care engagement in MSM. Therefore, we assessed characteristics associated with having a primary care provider (PCP), and among MSM with a PCP, trust in and disclosure of same-sex behaviors to a PCP.

METHODS: In 2016, 4,239 MSM (aged 18+, reporting 1 sex act with a man in past 5 years) from across the US, recruited via diverse social media sites and in-person, completed an online survey including demographic/behavioral characteristics, health literacy and (1) *having a PCP*, and among those with a PCP, (2) *trust in their PCP* (using Wake Forest Physician Trust Scale, dichotomized at the mean), and (3) *disclosure of same-sex behaviors to their PCP*. We used multivariable logistic regression with GEE to identify characteristics associated with each of the 3 outcomes. All results adjusted for age, race/ethnicity, HIV status, state, urbanicity, and recruitment source and shown as (Adj Odds Ratio, 95% CI).

RESULTS: Participants were from all 50 US states and distribution was roughly equivalent across age groups. Over half identified as white (59.8%), 19.1% as Latino, 10.6% as black, and 3.4% as Asian. Most identified as gay (79.7%) or bisexual (17.6%). 18.2% reported being HIV-positive, 62.8% HIV-negative-not on pre-exposure prophylaxis (PrEP), 11.5% HIV-negative-on PrEP and 7.6% unsure of their HIV status. Most (86.3%) had a PCP. The odds of *having a PCP* was lower ($p<0.01$) among those who were younger (0.09, 0.03-0.3; ref: 65+), HIV-negative (0.08, 0.04-0.15; ref: HIV+) or -unknown (0.05, 0.03-0.1), single (0.7, 0.5-0.8), or with low medical literacy (0.7, 0.5, 0.9). Of those with a PCP ($n=3,658$), 45.3% had *low trust in their provider*, which was associated with ($p<0.01$) being younger (0.6, 0.4-0.9), Asian (0.67, 0.45-1; ref: white), bisexual (0.7, 0.6-0.8; ref: gay), HIV-negative-not on PrEP (0.5, 0.4-0.6; ref: HIV+), HIV-unsure (0.3, 0.2-0.4), or with low medical literacy (0.4, 0.3-0.5). Finally, among those with a PCP ($n=3,658$), 24.5% had *not disclosed same-sex behaviors* to their provider. Non-disclosure was associated with ($p<0.01$) being Asian (0.5, 0.3-0.8), bisexual (0.2, 0.2-0.3) or straight (0.05, 0.02-0.1), HIV-negative or -unknown (0.09, 0.06-0.14), having no sex partners in past 3 months (0.6, 0.5-0.8; ref: >1 partner), recruited from hookup sites, low medical literacy (0.7, 0.5, 0.9), and having low trust in their PCP (0.6, 0.5-0.7).

CONCLUSIONS: We found a number of factors associated with having a PCP and, among those with a PCP, we identified a number of predictors of primary care engagement, indicated by trust in a PCP and disclosure of same-sex behaviors. Research is needed to evaluate if increasing patient-provider trust and creating an enabling environment for disclosing same-sex behaviors can improve primary care engagement among diverse MSM populations.

DIFFERENCES IN RISK FACTORS BETWEEN GENDERS FOR PATIENTS READMITTED WITH ACUTE PANCREATITIS A RETROSPECTIVE COHORT STUDY

Neal Mehta¹; Gilbert-Roy B. Kamoga²; Khaled Khasawneh¹; Ron T. Varghese². ¹White River Health System, Batesville, AR; ²White River Medical Center, Batesville, AR. (Control ID #3184581)

BACKGROUND: In the United States, Acute Pancreatitis (AP) is the most frequent discharge diagnosis within Gastroenterology [1]. Those that have been admitted within 30-days have increased mortality at the 1-year mark [2]. Previous literature suggests that males have higher propensity for readmission for AP [3]. We sought out to determine the 30-day all-cause readmission rate for adults (age ≥ 18) readmitted with a principal diagnosis of AP and compare the risk factors for males and female.

METHODS: We utilized Agency of Healthcare Research and Quality's (AHRQ) 2014 Nationwide Readmission Database which includes 14.9 Million discharges across 22 states to identify admissions with a principal diagnosis of AP (ICD-9 577.0). Applicable admissions were all adults (age ≥ 18) with an index hospitalization discharge from January 1 to November 30, 2014. Patients who died during index admission or those with missing covariates were excluded. All-cause including AP readmissions within 30-days of an AP admission were analyzed. Statistical analysis was completed with Stata 15 (StataCorp, College Station, TX) with p-values < 0.05 considered statistically significant. A univariate and multivariate analysis of data collected was completed using both odds ratio and chi square tests for significance. Predictors for readmission were determined using a multivariate logistic regression model following sequential step-wise elimination of covariates including demographics, comorbidities, hospital characteristics, length of stay (LOS), and the modified Elixhauser Comorbidity Index.

RESULTS: A total of 112,374 patients met criteria for inclusion. Of which, there was 16,939 readmissions (overall rate 15.07%) within 30-days of the index admission. Of the 16,939 readmissions, 7,180 (42.38%) had a principal diagnosis of AP. Males were readmitted for AP at a rate of 44.84% while females were readmitted at 39.48%. Multivariate analysis showed that increased odds for 30-day readmission for acute pancreatitis (both genders) were admissions on weekend, younger, disposition at discharge (other facility, short term hospital, and leaving AMA), longer LOS, and admitted to medicine compared to surgery. For males, increased odds were admissions on weekend, younger, disposition at discharge (other facility, short term hospital, and leaving AMA), LOS between 7 and 14 days, and admitted to medicine. For females, increased odds were admissions during the week, younger, disposition at discharge (short term hospital, home with home health care, and AMA), longer LOS (>7 days), and admitted to medicine.

CONCLUSIONS: Male have a higher readmission rate for AP compared to females with slight differences in risk factors particularly admissions on weekend and LOS. Better understanding and development of interventions for individuals with risk factors and high-risk for readmission may help to reduce future morbidity and mortality. Sources: [1] Lankisch, Lancet, 2015. [2] Lee, Pancreas, 2016. [3] Vipperla, Clin Gastroenterol Hepatol, 2014.

DIFFERENCES IN THE EFFECT OF PRIMARY CARE - MENTAL HEALTH INTEGRATION ON HEALTHCARE UTILIZATION AMONG MEN AND WOMEN VETERANS

Lucinda B. Leung^{1, 5}; Lisa V. Rubenstein²; Edward P. Post³; Ranak Trivedi⁴; Sabine Oishi⁵; Alison Hamilton⁵; Jean Yoon⁶; Erin L. Jaske⁷; Elizabeth M. Yano⁸. ¹UCLA David Geffen School of Medicine & West LA VA Medical Center, Los Angeles, CA; ²RAND and UCLA, Medford, OR; ³VA Ann Arbor Healthcare System and University of Michigan, Ann Arbor, MI; ⁴VA Palo Alto Health Care System/Stanford University, Menlo Park, CA; ⁵Veterans Administration, Los Angeles, CA; ⁶Palo Alto VA, Menlo Park, CA; ⁷Department of Veteran Affairs, Seattle, WA; ⁸VA Greater Los Angeles Healthcare System, Sepulveda, CA. (Control ID #3179172)

BACKGROUND: Evidence-based collaborative care models, such as VA's Primary Care Mental Health Integration (PC-MHI), can improve patient access to treatment of depression and anxiety, which are more prevalent among women. Access to PC-MHI care varies among women Veterans, because VA primary care organization may differ by gender (e.g., separate clinics for men and women). We examined whether greater primary care clinic penetration in PC-MHI care over time was associated with changes in healthcare utilization, particularly mental health visits, differently for women and men.

METHODS: We examined 448,455 female and 4,928,638 male patients receiving primary care between October 1, 2013 and September 30, 2016 from 396 hospital- or community-based VA clinics required to offer on-site PC-MHI services. In this national retrospective longitudinal cohort study, we calculated annual clinic PC-MHI penetration as the percent of assigned primary care patients seen by a PC-MHI provider. We used clinic PC-MHI penetration in multivariate regression models to predict specialty mental health visits (including PC-MHI visits) and other healthcare visits (i.e., primary care, other non-mental health specialty care, telephone, hospital stays). Models controlled for year, clinic, level of PACT implementation, utilization-related patient characteristics (e.g., age, gender, chronic comorbidities), and an interactive effect between gender and PC-MHI penetration.

RESULTS: Women, compared to men, had twice the rate of diagnosed depression (27% vs 15%; $p=.04$) and anxiety (17% vs 8%; $p=.5$). Women, on average, had higher rates of outpatient specialty mental health (1.7 times; $p<.001$) and primary care (1.3 times; $p<.001$) visits than men. Adjusted regressions showed, among women compared to men, 1 percentage-point greater clinic PC-MHI penetration was associated with a decrease in average specialty mental health visits (-38%, vs +39%), other specialty visits (-48%, vs -13%), and hospital stays (-74%, vs +2%), but an increase in primary care visits (+22%, vs +40%), for patients per year (all P 's $< .0001$). There were no observed gender differences in PC-MHI effects on telephone care.

CONCLUSIONS: Women Veterans have high rates of depression and anxiety, which can be effectively treated by PC-MHI models. Greater primary care clinic penetration in PC-MHI was associated with higher outpatient specialty mental health utilization among men, but lower utilization among women Veterans. While PC-MHI care models may increase engagement in outpatient services for men, greater clinic penetration in PC-MHI services may instead be shifting mental health care (and perhaps other non-mental health specialty care and acute care) to primary care providers for women Veterans. With increasing patient choice in where to receive care, the VA must tailor medical care to the needs of rising numbers of women patients. More research is needed to understand gender differences in mental healthcare access and utilization related to PC-MHI.

DIRECT OBSERVATION OF PATIENT EDUCATION BY THE HEALTHCARE TEAM ON THE DAY OF DISCHARGE

Shreya P. Trivedi¹; Sara Corderman²; Caroline Katzman¹; Mark D. Schwartz¹; Leora I. Horwitz¹. ¹NYU School of Medicine, New York, NY; ²SUNY Downstate College of Medicine, Brooklyn, NY. (Control ID #3179319)

BACKGROUND: The transition of care from hospital to home is a vulnerable time for patients, often leaving individuals with a suboptimal understanding of the care plan, which can lead to post-hospitalization morbidity and readmissions. Prominent national medical societies and health services interventions have identified important domains to be addressed on discharge. Yet,

there remains variable implementation of these high value discharge practices and often little transparency surrounding roles of medical team members at discharge. Direct field observation from the perspective of the patient is critical to inform gaps in the delivery of high quality discharge care. This study is the first to capture the discharge process by the entire healthcare professional team from the patient perspective.

METHODS: Purposeful sampling was used to select patients designated for "discharge by noon" with complex care plans. On the day of discharge, a research assistant sat at the bedside of a single consented patient from 6am until time of discharge, and recorded all communication and time spent on discharge education. Field notes were deductively analyzed for how patients were educated on key domains: medications, appointments, self-management of illness, symptom expectations, red flags, teach back and patient activation.

RESULTS: To date, 15 patients with a total of 92 hours of observations have been conducted. On average, interns spent about 4.5 minutes with the patient on discharge and less than 1 minute on discharge education. Nurses had variable discharge practices, which ranged from asking the patient to read printed discharge information to reading the discharge instructions to the patient. While most patients were told about medication changes, 40% were not told the purpose of medication changes. Similarly, the majority of patients were not told the purpose of follow-up medical appointments or pending results. There was limited education surrounding the self-management of diseases, symptom expectations or red flags. When provided, discharge education was one-sided; no patients were engaged through teach-back or patient activation. One patient was asked about potential barriers to adherence with the care plan. The majority of discharge communication was on practical steps of leaving the hospital, not preparing the patient to care for their themselves at home.

CONCLUSIONS: There is significant opportunity for improved discharge techniques to enhance safety and quality of care for patients leaving the hospital - including teach-back and patient engagement. Interventions must be implemented to increase patient education, particularly interprofessional ones that clarify assumptions on each other's roles. Further studies on effective communication strategies as well as systems redesign that foster patient-centered discharge education are imperative.

DISPARITIES IN COMMUNICATION AMONG THE INPATIENT HOMELESS POPULATION AT A SAFETY-NET HOSPITAL

Cristina Vellozzi-Averhoff¹; William W. Thompson²; Claudia Vellozzi³; Ike Okosun⁴; Kathy Kinlaw¹; Jada C. Bussey-Jones¹.

¹Emory University, Atlanta, GA; ²Reproducible Scientific Solutions, LLC, Atlanta, GA; ³Grady Memorial Hospital, Atlanta, GA; ⁴Georgia State University, Atlanta, GA. (Control ID #3177752)

BACKGROUND: Homelessness in the United States has a long history of stigma with little to no objective data on communication or care quality for the homeless. This research looks at the implications of stigma to determine whether the homeless population experiences disparities in care and communication during inpatient hospitalizations in a safety-net hospital.

METHODS: We administered a modified Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey to 112 age- and sex-matched homeless and non-homeless adults at a university-affiliated safety-net hospital from December 2017 through March 2018 and performed a retrospective review of medical records of the survey participants. Linear

regression models were used to assess differences in responses to survey subscales, length of stay, and other process of care measures.

RESULTS: Homeless participants trended toward poorer ratings for all HCAHPS subscales, reaching significance for the Communication about Medications subscale, with a mean score of 1.2 (95% CI 0.48 - 1.76) points lower compared to non-homeless sample. Length of stay and general process of care measures were not significantly different between homeless and non-homeless participants.

CONCLUSIONS: In an urban safety-net hospital, disparities in communications regarding medications between hospital staff and patients were found based on housing status, which may reflect systemic implicit bias of providers.

DISPARITIES IN DISPOSITION AND LENGTH OF STAY IN HOSPITALIZATIONS FOR SERIOUS INFECTIONS WITH AND WITHOUT OPIOID USE DISORDER

June-Ho Kim^{1, 2}; Danielle R. Fine³; Lily Li¹; Simeon D. Kimmelman⁴; Joji Suzuki¹; Christin N. Price¹; Matthew Ronan⁵; Shoshana J. Herzig⁶. ¹Brigham and Women's Hospital, Boston, MA; ²Ariadne Labs, Brigham & Women's Hospital and Harvard T.H. Chan School of Public Health, Boston, MA; ³Massachusetts General Hospital, Boston, MA; ⁴Boston Medical Center, Boston, MA; ⁵VA Boston, Hopkinton, MA; ⁶Beth Israel Deaconess Medical Center, Brookline, MA. (Control ID #3185253)

BACKGROUND: Patients with opioid use disorder (OUD) and serious bacterial infections, which often require prolonged courses of intravenous antibiotics, may face disparities in hospital and post-acute care, potentially leading to more discharges against medical advice (AMA), longer hospital stays, and higher costs. We compared differences in disposition, length of stay (LOS), and hospital charges between hospitalizations of patients with serious infections with and without OUD.

METHODS: We analyzed a nationally representative cohort of U.S. hospitalizations using the 2016 National Inpatient Sample. We included all adult (age 18+) hospitalizations with a primary ICD-10 diagnosis code for endocarditis, osteomyelitis, septic arthritis, or epidural abscess. The exposure of interest was OUD, identified as a secondary code. Outcomes were LOS, discharge disposition, and total hospital charges. Baseline characteristics were compared using chi-square tests and t-tests for categorical and continuous variables, respectively. Multivariable models were adjusted for patient, hospitalization, and hospital-level characteristics. We used multivariable logistic and linear regression to estimate odds ratios for dispositions and differences in LOS and hospital charges, respectively.

RESULTS: In 2016, there were 91,015 hospitalizations in the U.S. for serious infections, 7,115 of which were associated with OUD. Patients with OUD were younger (mean age 41 vs 59), female (44 vs 35%), and white (73 vs 69%). More had Medicaid (58 vs 18%) or were uninsured (10 vs 5%, all p<0.01). Fewer hospitalizations with OUD ended in discharge to home (48 vs 66%, p<0.01); similar proportions were discharged to a post-acute care facility (30 vs 30%, p=0.96); and more were discharged AMA (20 vs 3%, p<0.01). Adjusted for covariates, hospitalizations with OUD had lower odds of discharge home (adjusted odds ratio, aOR 0.37, 95% CI 0.31, 0.43) and higher odds of discharge to a post-acute care facility (aOR 1.76, 95% CI 1.48, 2.09) or AMA (aOR 3.08, 95% CI 2.47, 3.83). Hospitalizations with OUD had longer mean lengths of stay (14 vs 8 days, p<0.01), higher average total hospital charges (\$109,476 vs 74,400, p<0.01), and lower average daily charges (\$8,454 vs 9,856, p<0.01). After accounting for potential confounders,

hospitalizations with OUD still had an average 3.3 days longer length of stay ($p<0.01$).

CONCLUSIONS: U.S. hospitalizations in 2016 for serious infections in patients with OUD had significantly longer lengths of stay and greater associated costs, along with higher odds of discharge to a post-acute care facility or AMA as opposed to home, compared to those without OUD. Further studies elucidating the source of these disparities and interventions to address them (such as more access to post-acute care facilities, inpatient substance use treatment, transitional addiction clinics, and outpatient parenteral antibiotic therapy) may improve equity of care and lower costs.

DISPARITIES IN PHYSICIAN-PATIENT NONVERBAL COMMUNICATION AND INFLUENCE ON PATIENT ADHERENCE

Kedous Mekbib; Carol Oladele; Marcella Nunez-Smith. Yale University, New Haven, CT. (Control ID #3186084)

BACKGROUND: Physician-patient communication is a quality of care indicator that has demonstrated associations with patient experience, satisfaction, and healthcare outcomes. Findings show that physician-patient communication varies across patient sociodemographic groups and contributes to healthcare disparities. This body of research has primarily focused on verbal physician-patient communication. Few studies have investigated the influence of nonverbal physician-patient communication on healthcare disparities. This study aimed to examine differences in physician nonverbal communication among diverse patient groups and to determine the relationship between nonverbal communication and patient adherence.

METHODS: Data from the Patient-reported Experiences of Discrimination in Care Tool (PreDict) Study was used for the current analysis. The PreDict study includes a self-administered survey of recently discharged adult patients from a sample of US hospitals. Patients were asked about their most recent inpatient experiences using de novo items and previously validated scales. Nonverbal communication was measured by asking patients if their doctors were distracted when talking, stayed physically distant, and made eye contact with them. Our outcome, patient adherence, was measured using items that assessed whether patients were following discharge instructions or taking medications as prescribed. Chi-square tests were used to compare differences in nonverbal communication by race, ethnicity, total household income, and level of education. Logistic regression models were used to determine associations between nonverbal communication and patient adherence, adjusting for potential confounders.

RESULTS: Ninety-one percent of respondents reported their doctor was not distracted, 71.8% reported their doctor was not physically distant, and 88.6% of respondents reported their doctor made eye contact. Ninety-seven percent of respondents said they followed discharge instructions and 89.2% of patients took their prescribed medications. Bivariate analyses showed that lower income and non-white patients reported physicians maintained less eye contact and were distracted when talking to them. Multivariate results showed that patients who reported that doctors maintained less eye contact had 2.54 times lower odds of adhering to discharge instructions. Findings for medication adherence were not statistically significant.

CONCLUSIONS: These findings demonstrate that nonverbal communication matters to patients and is an important factor to consider in efforts to improve patient adherence. Findings also suggest the potential role of implicit bias in disparate physician-

patient communication experiences among low-income and minority patients. This study highlights the need for increased provider awareness of nonverbal behaviors that contribute to poor healthcare outcomes and disparities.

DO CLINICIAN-EDUCATORS FEEL THEY ARE ADEQUATELY MENTORED: A MIXED-METHODOLOGY STUDY

Attila Nemeth¹; Alia Chisty²; Carla Spagnolletti³; Corrie A. Stankiewicz⁴; Subha Ramani⁵. ¹Case Western Reserve University, Cleveland, OH; ²Temple, Philadelphia, PA; ³University of Pittsburgh, Pittsburgh, PA; ⁴University of Pennsylvania SOM, Narberth, PA; ⁵Brigham and Women's Hospital, Harvard Medical School, Boston, MA. (Control ID #3184642)

BACKGROUND: Being mentored is key to professional advancement, job satisfaction and institutional faculty retention. While many institutions have formal mentoring programs, it is unclear if clinician-educators (CE) feel that such programs adequately address professional development.

METHODS: A mixed methods approach explored the mentoring experiences and perceptions of general internal medicine CEs, focusing on the adequacy and quality of being mentored. To gather quantitative and qualitative data, an online survey was distributed to self-identified CEs within the Society of General Internal Medicine (SGIM) in the fall of 2017, and two in-person focus groups of interested survey respondents were held at the SGIM Annual Meeting in 2018. Pearson Chi-squared analysis was used for quantitative data and thematic analysis was conducted on qualitative data.

RESULTS: 192 CEs completed the survey. 64% of respondents were women, 79% were between 30-55 years, 68% were at the Assistant or Associate professor rank. 81% of women vs 59% of men had at least 1 active mentor ($p<0.001$). 40% had >3 active mentors, and 28% had none. 66% of respondents agreed or strongly agreed that they received adequate mentoring, and 94% agreed or strongly agreed that mentoring was beneficial for career advancement. 80% agreed or strongly agreed that being mentored contributed to increased academic products. 79% either agreed or strongly agreed that mentoring challenged them to be better CEs. Gender comparisons of results indicated more women faculty sought out their own mentors (64% vs 44%, $p<0.01$), had mentors outside of their home institution (34% vs 18%, $p<0.05$), and used peer mentoring (33% vs 16%, $p<0.01$). Women used mentoring sessions to discuss career advancement (71% vs 42%, $p<0.001$), job satisfaction (48% vs 28%, $p<0.01$), developing educational products (66% vs 41%, $p<0.01$), personal/professional life balance (45% vs 27%, $p<0.01$), negotiating tactics (28% vs 4%, $p<0.01$), and deciding which opportunities to pursue (66% vs 46%, $p<0.01$). Gender congruence between mentor and mentee was important. 70% of responding women had a primary mentor who was female, and 68% of men had a primary mentor who was male ($p<0.01$). We discovered the following key themes from our qualitative data: (1) an effective mentor is vital for career advancement; (2) peer mentoring offers unique benefits for professional growth; (3) there are distinct challenges in mentoring CEs; and (4) it is unclear whether mentoring is a teachable skill.

CONCLUSIONS: Female CEs appear to be significantly more proactive in seeking mentors inside and outside their institutions and engaging in peer mentoring. Even if institutions have formal faculty mentoring programs, mentoring that addresses unique needs of clinician educators is necessary for their career advancement and job satisfaction.

DO HOSPITALIZATIONS DISRUPT LOYALTY TO AMBULATORY CARE PROVIDERS?

Laura F. Gingras³; Jennifer Chester³; Sanjai Sinha²; Lisa M. Kern¹; Mangala Rajan³. ¹Weill Cornell Medical College, New York, NY; ²weill cornell medical college, New York, NY; ³Weill Cornell Medical College, New York City, NY. (Control ID #3185484)

BACKGROUND: Hospitalizations can be disruptive events, which result in new diagnoses, new treatments, and new providers for patients. The effect of hospitalizations on ambulatory care patterns, though, is not known. That is, it is not known whether patients return post-discharge to their pre-hospitalization ambulatory provider, or whether they follow up with the new providers they met in the hospital. The answer to this question has important implications for value-based purchasing contracts, which assign patients to providers based on ambulatory visit patterns yet hold providers accountable for all of their patients' care (including hospitalizations elsewhere).

METHODS: We conducted a retrospective cohort study (2014-2016) of commercially insured adult patients (18 years) who were attributed to a physician organization (PO) by a commercial payer for the purpose of a reimbursement contract. We included patients who were hospitalized in 2015 and, using chi-squared tests, analyzed their patterns of ambulatory care 6 months before vs. 6 months after the hospitalization. Using logistic regression, we determined if seeing a PO provider 6 months before the hospitalization was associated with seeing a PO provider 6 months after, adjusting for the location of the hospitalization, patient age, patient gender, and the type of admission (emergency or elective).

RESULTS: Of the 569 patients in our sample, all of whom were attributed to the PO, 311 (55%) were hospitalized at the affiliated hospital, whereas the remainder (N = 258, 45%) were hospitalized elsewhere. There was no difference in the proportion of patients with at least 1 ambulatory visit to any provider before vs. after the hospitalization ($p > 0.10$). However, patients who were hospitalized elsewhere were significantly less likely to have at least 1 visit with a PO provider in the 6 months before the hospitalization, compared to those hospitalized at the affiliated hospital (54% vs. 73%, $p < 0.0001$). Patients who were hospitalized elsewhere were also significantly less likely to have at least 1 visit with a PO provider in the 6 months after the hospitalization, compared to those hospitalized at the affiliated hospital (61% vs. 80%, $p < 0.0001$).

CONCLUSIONS: Hospitalizations did not change patterns of ambulatory care (that is, before vs. after the hospitalization). However, patients who were hospitalized elsewhere had less loyalty to the PO both before and after hospitalization than patients hospitalized at the affiliated hospital. This study raises important questions about whether attribution logic should be affected by hospitalizations and, separately, how well POs need to monitor their patients for hospitalizations elsewhere.

DO PATIENT SATISFACTION SCORES VARY BY PHYSICIAN RACE/ETHNICITY? AN EXPLORATION IN DIRECT TO CONSUMER TELEMEDICINE

Kathryn A. Martinez¹; Kaitlin Keenan²; Radhika Rastogi²; Joud Roufael³; Mark N. Rood⁴; Michael B. Rothberg¹. ¹Cleveland Clinic, Cleveland, OH; ²Cleveland Clinic Lerner College of Medicine, Cleveland, OH; ³Kent State University College of Public Health, Kent, OH; ⁴Cleveland Clinic Foundation, Chagrin Falls, OH. (Control ID #3183105)

BACKGROUND: The U.S. physician workforce is increasingly diverse and foreign medical graduates are common. Patient satisfaction is often publicly reported and can influence physician payment. Racial/ethnic bias against non-white physicians has been reported but not widely studied. The objective of this study was to assess differences in patient ratings of physicians in a large direct to consumer (DTC) telemedicine platform, by physician race/ethnicity.

METHODS: cross-sectional study of encounters conducted between July 2016 and July 2018 on the AmericanWell telemedicine platform. Four

independent and blinded reviewers of different racial/ethnic backgrounds categorized physicians into racial/ethnic groups based on name (e.g. "Juan Ramirez" would be coded as Hispanic, "Preethi Gupta" would be coded as Indian) and publicly available photos. Physicians for whom no consensus was reached were excluded. Patient satisfaction was assessed by the telemedicine system immediately following each encounter, measured on scales of 0 to 5 stars, analyzed continuously. To maximize stability of satisfaction estimates for each physician, only those with at least 20 encounters were included. Mixed effects linear regression was used to assess differences in satisfaction scores by physician race/ethnicity, accounting for clustering by physician. Patient covariates included age, gender and geographic region. The model also controlled for prescription receipt and coupon use for free or reduced-cost care, as both are highly associated with patient satisfaction with telemedicine.

RESULTS: The sample included 119,016 encounters with 390 physicians. Fifty-nine percent of physicians were categorized as White American, 14% Indian, 7% Black American, 7% Hispanic, 6% Arab and 6% Asian. For both White and Black American physicians, the unadjusted mean satisfaction score was 4.8, for both Arab and Hispanic physicians it was 4.7, and for both Indian and Asian physicians it was 4.5. In the adjusted mixed effects linear model, compared to White American physicians, satisfaction scores for Asian physicians were 0.24 points lower (95%CI:-0.26, -0.22), scores for Indian physicians were 0.24 points lower (95%CI:-0.26, -0.22), scores for Arab physicians were 0.16 points lower (95%CI:-0.18, -0.14), scores for Hispanic physicians were 0.05 points lower (95%CI:-0.08, -0.02), and scores for Black American physicians were 0.03 points lower (95%CI:-0.04, -0.01).

CONCLUSIONS: All groups of non-White American physicians were rated worse than White American physicians, with particularly lower scores for Arab, Indian, and Asian physicians. Even small differences in satisfaction scores can impact physician payment and reputation. Understanding whether lower scores for non-White American physicians were influenced by patient bias or differences in quality and/or practice style is critical.

DO PATIENTS WITH SUBCLINICAL HYPOTHYROIDISM WHO SUFFER FROM GREATER SYMPTOM BURDEN BENEFIT FROM LEVOTHYROXINE THERAPY? FURTHER ANALYSIS OF THE RANDOMIZED PLACEBO-CONTROLLED TRUST TRIAL

Maria de Montmollin^{1, 2}; Martin Feller^{1, 2}; Shanthi Beglinger^{1, 2}; Alex McConnachie³; Cinzia Del Giovane²; Rosalinde K. Poortvliet⁴; Drahomir Aujesky¹; Ian Ford³; Simon P. Mooijaart^{4, 4}; Torquil Watt⁵; Rudi G. Westendorp⁶; Patricia M. Kearney⁷; Jacobijn Gussekloo^{4, 4}; David J. Stott⁸; Nicolas Rodondi^{1, 2}; Douglas Bauer⁹. ¹Bern University Hospital, Bern, Switzerland; ²Institute of Primary Health Care (BIHAM), University of Bern, Bern, Switzerland; ³Institute of Health and Wellbeing, University of Glasgow, Glasgow, United Kingdom; ⁴Leiden University Medical Center, Leiden, Netherlands; ⁵Copenhagen University Hospital Herlev, Copenhagen, Denmark; ⁶University of Copenhagen, Copenhagen, Denmark; ⁷University College Cork, Cork, Ireland; ⁸Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, United Kingdom; ⁹University of California, San Francisco, CA. (Control ID #3170456)

BACKGROUND: A recent large trial and meta-analysis of all RCTs found that levothyroxine does not improve hypothyroid symptoms or quality of life among adults with subclinical hypothyroidism (SCH). However, those who report higher symptom burden prior to treatment might still benefit. The aim of this analysis is to determine whether levothyroxine, compared to placebo, improves hypothyroid physical symptoms and tiredness among older adults with SCH and higher symptom burden.

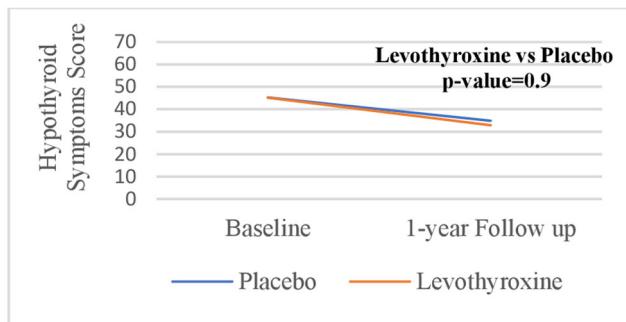

METHODS: We analyzed data from adults 65 years with persistent SCH (TSH 4.6-19.9 mIU/L for >3 months, normal fT4) included in the TRUST trial, a multicenter, double blinded, placebo-controlled, randomized trial.

Participants were randomized to levothyroxine or matching placebo including mock titration. The main outcomes were the change in 1-year Hypothyroid Symptoms score and Tiredness score in the Thyroid-Related Quality-of-Life Questionnaire. Both scores were self-reported (range 0-100, higher scores indicate more symptoms) with a 9 point difference considered clinically significant. In this subgroup analysis, we focus on participants with a baseline Hypothyroid Symptoms score >30 or Tiredness score >30.

RESULTS: At baseline, 132 adults (20.7%) had Hypothyroid Symptoms scores >30 (mean age of 75 years, 64% women, mean \pm SD TSH 6.2mIU/L \pm 1.65 and mean Hypothyroid Symptoms score 45.2 \pm 14.6) and 209 (32.8%) had Tiredness scores >30 (mean age of 75 years, 63% women, mean TSH 6.2mIU/L \pm 1.65 and mean Tiredness score 48.9 \pm 14.9). After 1 year, among those with a Hypothyroid Symptoms score >30 at baseline, the mean score was 34.9 in the placebo and 32.8 in the levothyroxine group; and in those with a baseline Tiredness score >30, 43.1 and 41.3 respectively. 1-year outcomes were similar between the levothyroxine and placebo groups (adjusted between-group difference -0.5, 95%CI: -6.8 to 5.8, p=0.9, Figure 1; and -0.7, 95% CI: -6.1 to 4.8, p=0.8, respectively). Among all TRUST participants (n=737), baseline scores of the two main outcomes (as continuous variables) did not modify the effects of levothyroxine vs. placebo on Hypothyroid Symptoms (interaction p value=0.85) or Tiredness (p=0.65).

CONCLUSIONS: In this secondary analysis of older adults with SCH and higher symptom burden at baseline, levothyroxine therapy did not improve hypothyroid symptoms or tiredness.

Figure 1. Effect of Levothyroxine vs Placebo on 1-Year Change in Hypothyroid Symptoms Scores in Older Adults with Subclinical Hypothyroidism and Baseline Scores >30 (N=132)

DO QUALITY IMPROVEMENT PROJECTS AFFECT WORK-FORCE BURNOUT?

Robert G. Badgett; Brent A. Duran. KU School of Medicine - Wichita, Wichita, KS. (Control ID #3181672)

BACKGROUND: Burnout among healthcare professionals is a threat to both workforce and patient well-being. Based on Spreitzer's Integrative Model of Human Growth at Work, execution of quality improvement (QI) projects could be posited to reduce burnout if the workforce gains control over a dysfunctional worksite or to increase burnout if the workforce loses autonomy. This meta-analysis explores the link between workforce participation in the design of QI or practice redesign initiatives and impact on levels of burnout.

METHODS: We included studies published through January 2019 that executed QI projects, measured burnout, and had either concurrent or historical controls.

RESULTS: Six controlled studies with 6842 healthcare professionals were included. 66% of professionals were in the VA PACT study. One study, the Healthy Work Place (HWP) trial, was randomized. All interventions included components of workflow improvement. Two studies used a controlled before and after design to compare changes in burnout in intervention vs control clinics (Group Health Cooperative and Sutter Clinic). Meta-

analysis showed no overall effect on burnout (odds ratio: 0.95; 95% CI 0.74 to 1.23); however, heterogeneity was substantial (I²=72%). Whether healthcare professionals had local control over project design significantly modulated the results: studies granting local control tended to reduce burnout (odds ratio 0.77; 95% CI 0.57 to 1.03; I²=44%) whereas studies not clearly granting local control tended to increase burnout (odds ratio 1.29; 95% CI 0.91 to 1.81; I²=80%). Additional findings include: 1) the Sutter clinic found that interventions did not affect burnout when the workforce had control over implementation, but the same interventions significantly increased burnout when the workforce did not have control, 2) the HWP found that workflow interventions significantly reduced burnout, 3) two studies found a significant association between the degree of practice redesign and freedom from burnout, and 4) Group Health reported a positive financial return on investment. A qualitative study by Parker advocated for a hybrid approach to QI that merges central and local control of implementation. Studies with patient outcomes reported either significant benefit (VA PACT, Group Health, Sutter Clinic) or mixed results (HWP).

CONCLUSIONS: Burnout can be avoided, and likely reduced by both workforce involvement in implementation decisions and also addressing workflow. The recommendation for a hybrid strategy is consistent with the High-Performance Work Practices of the Agency for Healthcare Research and Quality and is consistent with complexity leadership theory (CLT). In CLT, the role of management includes data gathering, sensemaking of the data, and dissemination of information. Limitations to this analysis include relying on mostly non-registered, observational studies. The benefit to patient outcomes tends to be positive.

DOES A FOCUSED TRAINING IMPROVE INTERNAL MEDICINE RESIDENTS' SYSTEM- AND PRACTICE-BASED CONFIDENCE IN INTEGRATED BEHAVIORAL HEALTH CARE?

Christine A. Pace¹; Lindsay B. Demers²; Carly Taylor⁵; Evonne Yang³; Cara Fuchs³; Robert Joseph³; Daniel P. Alford⁴. ¹Boston University School of Medicine, Boston, MA; ²Boston University, Boston, MA; ³Boston Medical Center, Boston, MA; ⁴Boston University School of Medicine and Boston Medical Center, Boston, MA; ⁵Tufts University School of Medicine, Boston, MA. (Control ID #3185720)

BACKGROUND: Successful implementation of integrated behavioral health (IBH) requires physicians to take on new system-based and clinical responsibilities that are not well covered in residency training. The Boston Medical Center General Internal Medicine practice, where almost 100 residents receive ambulatory training, began an IBH program in 2014. Due to the large number of educational priorities for the residency program, we had limited time with the residents and developed a focused training. We sought to evaluate its effectiveness in improving residents' IBH system- and practice-based confidence.

METHODS: The training was an hour-long lecture with case discussion, focused on screening and intervening for depression and unhealthy substance use, and best practices for co-management with behavioral health clinicians. For example, we discussed interpretation of screening results, brief interventions for risky alcohol use, and behavioral health tools in our electronic record, and we modeled warm hand-offs to IBH clinicians. We trained four groups of residents, with each session led by a primary care clinician, psychologist or psychiatrist, and an IBH social worker. The training evaluation included a pre- and immediate-post-survey of residents assessing confidence in IBH processes and clinical skills. Changes in confidence were assessed using a five-point scale ranging from "Not at all Confident"=1 to "Completely Confident"= 5. A series of non-parametric sign tests appropriate for Likert-type data was used.

RESULTS: 31 residents completed the training with 27 (87%) completing the surveys. 17 were in their first year, 7 in their second, and 3 in their third. In order to assess changes in confidence from pre- to post-, a series of non-parametric sign tests, appropriate for Likert-type data, was used. We found statistically significant gains in confidence in all areas assessed.

CONCLUSIONS: A focused internal medicine resident training combining lecture with case discussion was effective in increasing residents' confidence in incorporating IBH into their outpatient practice. In a training environment with multiple competing priorities, efficient approaches that address systems-based practice are particularly important.

DOES A HIGHER LEVEL OF EDUCATION TRANSLATE INTO A LOWER PREVALENCE OF CARDIOVASCULAR DISEASE

Taher M. Tayeb¹; Talal Alzahrani²; Marco Mercader². ¹The George Washington University, Arlington, VA; ²The George Washington University hospital, Washington, DC. (Control ID #3141282)

BACKGROUND: Education is one of the determinants of health as described by the WHO, and it is one of the primary determinants of Socio-Economic Class (SEC), a higher level of education is associated with a higher level of SEC. Few researchers have addressed the link between the level of education and cardiovascular disease. However, there remains a need for a national study to determine the relationship between the level of education and cardiovascular disease. In this study, we investigated the effect of the level of education on the rate myocardial infarction (MI) and cardiovascular risk factors including diabetes mellitus, hypertension, hypercholesterolemia, and smoking status.

METHODS: The National Health Interview Surveys of 2016 (n=73,353) were utilized to measure the effect of level of education on MI and other risk factors. Subjects were assigned into four groups based on the level of education. The first group labeled as no education till the 12th grade, the second group identified as General Education Diploma (GED) or a high school diploma, the third group included subjects with some college, associate degree or bachelor, and the fourth group designated for subjects with master's degrees, professional degrees, or doctorates. Logistic regression models were used to examine the association between level of education and cardiovascular risk factors. The final model examined the association between level of education and MI after adjusting for demographics and cardiovascular risk factors.

RESULTS: A higher level of education was associated with lower odds of having cardiovascular risk factors. The final logistic regression model revealed that subjects with GED and high school education (OR 0.80, 95% CI 0.65-0.97; p 0.027), subjects with some college degree/ bachelor degree (OR 0.74, 95% CI 0.61-0.90; p <0.003), and subjects with master degrees or professional degrees (OR 0.58, 95% CI 0.43-0.78; p <0.001) have lower odds of having MI compared to the first group after adjusting for other risk factors including age, gender, diabetes mellitus, hypertension, hypercholesterolemia, and tobacco use.

CONCLUSIONS: This study unveiled that a higher level of education is associated with a lower rate of myocardial infarction and cardiovascular risk factors.

DOES AN INDEX COMPOSED OF ROUTINE LABS DISCRIMINATE RISK OF MORTALITY BETTER THAN THE CHARLSON INDEX

Christopher T. Rentsch^{1, 2}; Janet P. Tate²; Laura Tarko⁴; Jacqueline Honerlaw⁴; Kelly Cho^{4, 5}; Yuk-Lam Ho⁴; Amy C. Justice^{2, 3}. ¹London School of Hygiene & Tropical Medicine, London, United Kingdom; ²Yale School of Medicine/VA Connecticut Healthcare System, New Haven, CT; ³Yale School of Public Health, New Haven, CT; ⁴VA Boston Healthcare System, Boston, MA; ⁵Brigham and Women's Hospital/Harvard Medical School, Boston, MA. (Control ID #3175306)

BACKGROUND: The diagnostic code adaptation of the Charlson Comorbidity Index has been used as a mainstay adjustment for overall disease burden by thousands of investigators for decades. Now that electronic health records (EHR) make large scale access to laboratory data possible, we ask whether the Veterans Aging

Cohort Study (VACS) Index, based on routinely available clinical laboratory data, provides superior discrimination of mortality to that of the Charlson Index.

METHODS: We conducted an analysis using data from the Department of Veterans Affairs Million Veteran Program, a volunteer cohort of >500,000 patients providing full access to their EHR data. Baseline was set at enrollment. Patients were followed up to five years. The VACS Index was calculated from hemoglobin, ALT, AST, platelets, creatinine, hepatitis C status, albumin, white blood count, body mass index, and age. The Charlson Index was calculated from age and ICD-9/10 diagnostic codes for acute myocardial infarction, congestive heart failure, peripheral vascular disease, cerebral vascular accident, dementia, pulmonary disease, connective tissue disorder, peptic ulcer, mild and severe liver disease, diabetes and diabetic complications, paraplegia, renal disease, cancer and metastatic cancer, and HIV/AIDS. Values for VACS Index and codes for Charlson Index were assessed in the year prior to baseline. We compared discrimination (*C*-statistics) and model fit (AIC) between Cox models assessing 30-day, 6-month, 1-year, and 5-year mortality using VACS Index and Charlson Index scores as the sole predictor. We then compared *C*-statistics of models assessing 1-year mortality stratified by sex, age, and race/ethnicity.

RESULTS: Among 313,691 participants with laboratory data, median age was 64 years (IQR 55-70), 91% were male, 67% were European-American, and 21% were African-American. At 30 days, 6 months, 1 year, and 5 years, there were 370 (1.4 per 100 person-years [PY]), 1,383 (2.4/100 PY), 8,106 (2.7/100 PY), and 28,889 deaths (3.1/100 PY), respectively. *C*-statistics were significantly higher for VACS Index than Charlson Index at every time interval (*C*, 0.812 [95% CI, 0.789-0.836] vs. *C*, 0.759 [95% CI, 0.733-0.786] at 30 days; *C*, 0.765 [95% CI, 0.762-0.768] vs. *C*, 0.752 [95% CI, 0.749-0.755] at 5 years) and among men, participants aged 45 years, and European-Americans. Model fit was better for VACS Index than Charlson Index at every time interval. Of note, a benefit for Charlson is that there are no missing data since conditions are assumed absent if not coded; *C*-statistics for Charlson among those without laboratory data were consistent with those having laboratory data (data not otherwise shown).

CONCLUSIONS: The VACS Index, based on routinely available laboratory data, provides superior discrimination of mortality compared to that of the Charlson Index based on ICD codes. Now that EHRs can provide laboratory data on a large scale, the Charlson Index should no longer be the preferred method of risk adjustment.

DOES DIABETES EDUCATION INFLUENCE GLYCOSYLATED HEMOGLOBIN?

Pooja Bhargava¹; Linda Keller-Doyle¹; Eric Green². ¹Mercy Catholic Medical Center, Philadelphia, PA; ²Mercy Catholic Medical Center, Darby, PA. (Control ID #3180218)

BACKGROUND: Even though patient education is considered an essential component of diabetes management, little is known about the effectiveness of formal diabetes management classes.

METHODS: Mercy Catholic Medical Center (MCMC) offers a four-week class in self-management of diabetes. The classes are free, taught by certified diabetes educators, and are offered at times believed to be convenient for members of our community. The curriculum addresses diabetes pathophysiology, self-management of glucose, healthy eating, medications, healthy coping, and the benefits of exercise. We evaluated the impact of diabetes education on a cohort of patients who attended diabetes classes between 2015 and 2018. Patients had glycosylated hemoglobin (HgbA1c) measured before and after classes as part of routine care. We limited our analysis to

patients who had recorded HgbA1c before and 3-6 months after taking the classes. We used a paired t-test to determine statistical significance.

RESULTS: Of 296 patients completed diabetes education between 2015 and 2018, 139 patients (46%) met inclusion criteria. The mean age was 58, and 58% were female. The mean HgbA1c was 7.2 ± 1.4 prior to the class and 6.6 ± 1.1 at the next measured HgbA1c at least 3 months after taking the class ($p < .001$ for change). No significant difference was seen in impact of intervention between men (-0.57 ± 1.4) or women (-0.59 ± 1.1).

CONCLUSIONS: In this patient population, diabetes education classes produced a statistically significant and clinically meaningful reduction in HgbA1c. Our findings are limited by our inclusion criteria for patients with pre- and post-education HgbA1c; this population had a relatively low baseline HgbA1c and the impact of the behavioral intervention may be exaggerated by unmeasured confounders that also led to adherence with lab monitoring. Future research should be done to assess the impact of diabetes education classes on other populations.

DOES HOSPITAL TEACHING STATUS INFLUENCE RISK FACTORS AND INCIDENCE RATE OF 30-DAY READMISSION FOR ATRIAL FIBRILLATION

Ankitha Antony¹; Ron T. Varghese¹; Gilbert-Roy B. Kamoga²; Khaled Khasawneh¹; Neal Mehta¹. ¹White River Health System, Batesville, AR; ²White River Medical Center, Batesville, AR. (Control ID #3184827)

BACKGROUND: Atrial Fibrillation (AF) is a common arrhythmia accounting for nearly 1/3 of all cardiac rhythm admissions with hospital admissions for AF increasing by 70% over the past several years [1]. Furthermore, previous literature suggests that teaching hospitals may have higher readmission rates compared to non-teaching hospitals [2]. We sought out to determine the 30-day all-cause readmission rate for adults (age ≥ 18) admitted with a principal diagnosis of AF and compare the risk factors for teaching and non-teaching metropolitan hospitals.

METHODS: We utilized Agency of Healthcare Research and Quality's (AHRQ) 2014 Nationwide Readmission Database which includes 14.9 Million discharges across 22 states to identify admissions with a principal diagnosis of Atrial Fibrillation using ICD-9 code 427.31. Applicable admissions were all adults (age ≥ 18) with an index hospitalization discharge between January 1 to November 30, 2014. Patients who died during index admission and those with missing covariates were excluded. Index admissions to non-metropolitan hospital were excluded. All-cause including Atrial Fibrillation readmissions within 30-days of an Atrial Fibrillation were analyzed. Statistical analysis was completed with Stata 15 (StataCorp, College Station, TX) with p-values < 0.05 considered statistically significant. A univariate and multivariate analysis of data collected was completed using both odds ratio and chi square test for significance. Predictors for readmission were determined using a multivariate logistic regression model following sequential step-wise elimination of covariates including demographics, comorbidities, hospital characteristics, length of stay (LOS) for index admission, and the modified Elixhauser Comorbidity Index.

RESULTS: A total of 127,156 patients met criteria for inclusion. There were 21,384 readmissions (overall rate 16.82%) within 30-days of the index admission. Of the 21,384 readmissions, 5,589 (26.17%) had a principal diagnosis of Atrial Fibrillation. Metropolitan teaching hospitals had an overall readmission rate of 14.43% compared to 14.32% of non-teaching metropolitan hospitals (not statistically significant). Multivariate analysis showed that for metropolitan hospitals in general, younger age, weekend

admissions, association with renal failure, Medicaid insurance, different disposition at discharge (including leaving AMA, going home with home health or to a short-term hospital or other facility) all increased the odds for 30-day readmission from Atrial Fibrillation.

CONCLUSIONS: In general, nearly 1 in 6 patients discharged with a principal diagnosis of Atrial Fibrillation will be readmitted within 30 days. Metropolitan teaching and non-teaching hospitals have similar readmission rates and profile. Provider awareness of risk factors for readmissions in metropolitan hospitals will allow for the development of interventions to decrease future morbidity and mortality. References: [1] Anter, Circulation, 2009. [2] Mueller, Med Care, 2013.

DOES HOSPITAL TEACHING STATUS INFLUENCE RISK FACTORS AND INCIDENCE RATE OF 30-DAY READMISSION FOR CONGESTIVE HEART FAILURE IN THE UNITED STATES?

Shoaib Khan¹; Ron T. Varghese¹; Gilbert-Roy B. Kamoga²; Khaled Khasawneh¹; Neal Mehta¹. ¹White River Health System, Batesville, AR; ²White River Medical Center, Batesville, AR. (Control ID #3185493)

BACKGROUND: Congestive Heart Failure (CHF) admissions continue to rise with nearly 1 Million hospitalizations annually [1]. Furthermore, previous literature suggests that teaching hospitals may have higher readmission rates compared to non-teaching hospitals [2]. We sought out to determine the 30-day all-cause readmission rate for adults (age ≥ 18) admitted with a principal diagnosis of CHF and compare the risk factors for readmission at teaching and non-teaching metropolitan hospitals.

METHODS: We utilized Agency of Healthcare Research and Quality's (AHRQ) 2014 Nationwide Readmission Database which includes 14.9 Million discharges across 22 states to identify admissions with a principal diagnosis of CHF using ICD-9 codes (402.01, 402.11, 402.91, 404.01, 404.11, 404.03, 404.13, 404.91, 404.93 and 428.XX). Applicable admissions were all adults (age ≥ 18) with an index hospitalization discharge between January 1 to November 30, 2014. Patients who died during index admission and those with missing covariates were excluded. All index admissions to non-metropolitan hospital were excluded. All-cause including CHF readmissions within 30-days of a CHF readmission were analyzed. Statistical analysis was completed with Stata 15 (StataCorp, College Station, TX) with p-values < 0.05 considered statistically significant. A univariate and multivariate analysis of data collected was completed using both odds ratio and chi square tests for significance. Predictors for readmission were determined using a multivariate logistic regression model following sequential step-wise elimination of covariates including demographics, comorbidities, hospital characteristics, length of stay (LOS) for index admission, and the modified Elixhauser Comorbidity Index.

RESULTS: A total of 354,681 patients met criteria for inclusion. Of which, there were 78,588 readmissions (overall rate 22.15%) within 30-days of the index admission. Of the 78,588 readmissions, 31,030 (39.48%) had a principal diagnosis of CHF. Metropolitan teaching hospitals had an overall readmission rate of 22.203% compared to 22.06% at non-teaching metropolitan hospitals with the difference not statistically significant. Multivariate analysis showed that for metropolitan hospitals in general increased odds for 30-day readmission from CHF were weekend admissions, younger, any different disposition at discharge than routine (other facility, short term hospital, with home health, and leaving AMA), Medicaid as payer, central metropolitan areas with population > 1 million, longer LOS, and lower household income.

CONCLUSIONS: With almost 1 in 4 patients discharged with a principal diagnosis of CHF will be readmitted within 30 days. Metropolitan and non-teaching hospitals have similar readmission rates and profile. Provider awareness of risk factors for readmissions in metropolitan hospitals will help in planning interventions to decrease morbidity and mortality. References: [1] Roger. Circ Res. 2013. Aug 30;113(6):646-59. [2] Mueller. Med Care. 2013 Jul;51(7):567-74.

DOES HOSPITAL TEACHING STATUS INFLUENCE RISK FACTORS AND INCIDENCE RATE OF 30-DAY READMISSION FOR DIABETIC KETOACIDOSIS?

Ron T. Varghese; Diana G. Jacob; Gilbert-Roy B. Kamoga; Khaled Khasawneh; Neal Mehta. White River Medical Center, Batesville, AR. (Control ID #3184547)

BACKGROUND: Nearly 1 in 10 individuals in the United States have Diabetes Mellitus [1]. One potential preventable complication is Diabetic Ketoacidosis (DKA). Better understanding of the risk factors for readmissions of DKA will allow the development and implementation of specific patient-centered interventions to decrease future readmissions. Furthermore, previous literature suggests that teaching hospitals may have higher readmission rates compared to non-teaching hospitals [2]. We sought out to determine the 30-day all-cause readmission rate for adults (age ≥ 18) admitted with a principal diagnosis of DKA and compare the risk factors for teaching and non-teaching metropolitan hospitals.

METHODS: We utilized Agency of Healthcare Research and Quality's (AHRQ) 2014 Nationwide Readmission Database which includes 14.9 Million discharges across 22 states to identify admissions with a principal diagnosis of DKA related ICD-9 diagnosis (250.10 - 250.13) associated with both Type 1 and Type 2 Diabetes Mellitus. Applicable admissions were all adults (age ≥ 18) with an index hospitalization between January 1 to November 30, 2014. Patients who died during index admission and those with missing covariates were excluded. In addition, all index admissions to non-metropolitan hospital were excluded. All-cause readmission including DKA within 30-days of DKA were analyzed. Statistical analysis was completed with Stata 15 (StataCorp, College Station, TX) with p-values < 0.05 considered statistically significant. A univariate and multivariate analysis of data collected was completed using both odds ratio and chi square test for significance. Predictors for readmission were determined using a multivariate logistic regression model following sequential step-wise elimination of covariates including demographics, comorbidities, hospital characteristics, length of stay (LOS) for index admission, and the modified Elixhauser Comorbidity Index.

RESULTS: A total of 59,840 patients met criteria for inclusion. Of which, there was 11,635 readmissions (overall rate 19.44%) within 30-days of the index admission. Of the 11,635 readmissions, 6,329 (54.40%) had a principal diagnosis of DKA on the readmission. Metropolitan teaching hospitals had an overall readmission rate of 19.32% compared to 19.66% of non-teaching metropolitan hospitals which was not statistically significant. Multivariate analysis showed that for both teaching and non teaching metropolitan hospitals increased odds for 30-day readmission from DKA were female, younger, leaving AMA, Medicare as payer, longer LOS, having renal failure and admitted to a hospital that was either non-profit or investor-owned compared to a government entity.

CONCLUSIONS: Almost 20% of all patients discharged with a principal diagnosis of DKA will be readmitted within 30 days. Metropolitan teaching and non-teaching hospitals have similar

readmission rates and profile. Targeted interventions in patients at risk for readmission will help to decrease future morbidity and mortality.

DOES MEDICAID EXPANSION FOR VETERANS RESULT IN MORE DUAL USE OF VA AND NON-VA ACUTE HEALTH CARE SERVICES?

Patrick O'Mahen^{1, 2}; Laura A. Petersen^{1, 2}; Michael E. DeBakey VA Medical Center, Houston, TX; ²Baylor College of Medicine, Houston, TX. (Control ID #3184082)

BACKGROUND: Medicaid expansion may offer multiple sources of care for Veterans eligible for the VA, which creates potential dual use and may risk poorer care-co-ordination and health outcomes. Our goal is to examine how pre-Affordable Care Act state-level Medicaid expansions affect how many Veterans had a hospital admission or used emergency department (ED) at both Veterans Health Administration (VA) and non-VA Medicaid funded care.

METHODS: To account for confounders, we used a difference-in-difference approach to determine associations between Medicaid expansion and utilization among low-income Veterans ages 18-64 to eliminate age-related Medicare-eligible Veterans. We studied states that expanded Medicaid (New York, Arizona) to adults in 2001 or 2002 and paired them with demographically similar non-expansion states (Pennsylvania, New Mexico, Nevada) to isolate changes in ED visits and hospital admissions. We used ordinal logistic regression to separately estimate the proportion having hospital admissions or ED visits at both VA and non-VA facilities paid by Medicaid. We stratified by gender, race, and number of comorbid conditions. We controlled for age and distance to the nearest VA. Data sources were the VA Corporate Data Warehouse and the Medicaid Analytic Extract files. The study period encompassed 1,405,667 person years and represents every Veteran age 18-64 living in one of these five states for at least one year from 1999 to 2006 and qualified for VA care due to low income.

RESULTS: For women, Medicaid expansion was associated with an increase of 0.3 percentage points in the proportion of Veterans having hospital admissions at both Medicaid and VA facilities in a given year (99% CI -0.22 to 0.83) and 1.14 points in ED visits (.62 to 1.62). Men saw increases of 0.46 points for admissions (0.24 to 0.68) and 0.87 for ED visits (0.73 to 1.01). Among whites, expansion was associated with an increase of 0.64 points in proportions of Veterans having dual admissions (0.39 to 0.87) and 1.19 points in ED visits (0.62 to 1.66). Non-whites saw decreases of 0.01 points for admissions (-0.45 to 0.43) and an increase of 0.46 for ED visits (0.23 to 0.69). Among Veterans with no comorbid conditions, expansion was associated with an increase of 0.7 points in persons having dual admissions (-0.55 to 0.85) and 0.70 points in ED visits (0.62 to 1.66). Veterans with three or more comorbid conditions saw decreases of 0.09 points for admissions (-0.55 to 0.38) and increases of 0.62 for ED visits (0.27 to 0.98).

CONCLUSIONS: Medicaid expansion associates with small or no increased dual use of VA and Medicaid-funded services, suggesting problems like care coordination arising from dual use may be limited. Further work should explore dual use among vulnerable groups. This information may help project usage for both ACA and VA Choice programs, which expand access to non-VA care.

DOES REMOVING FINANCIAL INCENTIVES LEAD TO DECLINES IN MEASURED PERFORMANCE? INSIGHTS FROM MEDICARE ADVANTAGE STAR RATINGS PROGRAM

Rachel O. Reid^{1, 2}; Susan M. Paddock¹; Cheryl Damberg¹. ¹RAND Corporation, Boston, MA; ²Brigham and Women's Hospital, Boston, MA. (Control ID #3167588)

BACKGROUND: As policymakers face pressure to reduce measurement burdens, understanding what happens to measure performance after de-incentivization is important. The Centers for Medicare & Medicaid Services (CMS) publishes 5-star quality ratings for Medicare Advantage plans and pays Quality Bonus Payments to highly-rated 4- and 5-star plans. The Star Ratings incorporate measures from various sources [e.g., Healthcare Effectiveness Data and Information Set (HEDIS), Consumer Assessment of Healthcare Providers and Systems (CAHPS), Health Outcomes Survey (HOS)]. CMS has added and removed Star Rating measures over time; removed measures are still monitored and reported on cms.gov, but no longer contribute to bonus payments and are not publicly-reported on Medicare Plan Finder. No prior study has examined performance on measures removed from the Star Rating program.

METHODS: We examined 201 Medicare Advantage plans that received Star Ratings (i.e., Local Coordinated Care Plan (CCP), Medical Savings Account, Private Fee-for-Service, Regional CCP), were continuously present without mergers between 2009 and 2018, and had at least 1000 enrollees each year from 2009 to 2016. We excluded Puerto Rico plans. We assessed mean plan performance on Part C HEDIS, HOS, and CAHPS measures continuously reported to CMS for the 2009 to 2018 Star Ratings, excluding measures removed from the Star Ratings before 2012 or those temporarily removed for 1 or 2 years. We identified 13 measures that continuously contributed to Star Ratings and 6 measures removed from Star Ratings in 2012 or 2013.

RESULTS: Among the 6 measures removed from the Star Ratings, performance improved over the entire measurement period from 2009 to 2018 (from +2.2 percentage-points for "Doctors Who Communicate Well" to +8.7 percentage-points for "Testing to Confirm Chronic Obstructive Pulmonary Disease") and after removing the measure from Star Ratings (from +0.9 percentage-points for "Access to Primary Care Doctor Visits" to +6.7 percentage-points for "Testing to Confirm Chronic Obstructive Pulmonary Disease"). Among the 13 measures remaining in the Star Ratings between 2009 and 2018, performance trends varied from -0.3 percentage-points for "Getting Needed Care" to +21.6 percentage-points for "Osteoporosis Management in Women who had a Fracture". We did not observe declines in performance after measures were removed from the Star Ratings, compared to before removal and to performance on measures that remained incentivized in the Star Ratings.

CONCLUSIONS: Removing measures from the Medicare Advantage Star Ratings public reporting and financial incentives program did not result in performance declines, nor did performance trends differ from measures remaining in the Star Ratings. Payers and policymakers considering removing measures from public reporting or financial incentive programs should not necessarily anticipate worsening performance.

DOES TRAINING MATTER? ATTENDING PHYSICIANS' CORE CLINICAL SKILLS DO NOT APPEAR TO BE ANY BETTER THAN THOSE OF THEIR RESIDENTS.

Khemraj Hardowar; Lisa Altshuler; Colleen C. Gillespie; Jeffrey Wilhite; Harriet Fisher; Sarah Chaudhary; Kathleen Hanley; Sondra Zabar. NYU School of Medicine, New York, NY. (Control ID #3185414)

BACKGROUND: Considerable resources are put into training physicians to be effective providers after residency. Practicing physicians are generally assumed to be more effective and more efficient than resident physicians who are still undergoing training. We capitalize on a unique opportunity to test that hypothesis using the controlled methodology of Unannounced Standardized Patients (USPs), Standardized Patients sent into clinical environments to systematically assess provider skills in the context of a standardized clinical scenario. Due to last minute scheduling changes, a small

sample of attending physicians ended up seeing USPs we had intended to send to residents. In this study, we report on comparisons between how these attending physicians performed in terms of their patient centeredness, patient activation, assessment, and communication skills in comparison to residents.

METHODS: 6 USP visits were delivered to primary care clinics in an urban safety net hospital from 2009 to 2015. Of those 700+ visits, visits were completed inadvertently with 16 attendings. We selected the 16 attendings with at least 4 years of post-graduate experience and then matched them with 2 resident visits based on hospital, time period, and USP visit type (n=32 residents). In all visits, USPs completed a behaviorally anchored post-visit checklist that assessed patient centeredness (4 items), patient activation (2 items), visit-specific assessment (10 items), and communication skills including information gathering (4 items), relationship development (5 items) and patient education (3 items). Items were rated as *not done or partially done* vs. *well done* and summary scores were calculated as % well done. Mean scores for attendings and matched residents were compared using t-tests.

RESULTS: Resident and attending scores on patient centeredness (68% vs 73%), patient activation (44% vs 38%), assessment (53% vs 51%), patient education (49% vs 52%), information gathering (71% vs 78%) and relationship development (70% vs 73%) did not significantly differ ($p>.05$).

Nor did we see any substantial differences in variances or find any outliers. **CONCLUSIONS:** In our matched sample of residents and attendings, there were no significant differences by training level for any of the assessed clinical skills. While we viewed the inadvertent scheduling of USP visits with attendings as an opportunity to investigate the impact of training, our study is limited by the small sample size and whether we were able to create good matches. Findings may reflect ceiling effects (our checklists are too hard) or expertise-reversal effects (experts can skip some elements of the interaction and still arrive at the correct diagnosis and treatment plan). Further research, if our mistakenly-assessed attending sample increases, could explore the influence of PGY level and of patient load as attendings carry substantially heavier patient panels and see more (and probably more complex) patients per day than residents.

DOES URBAN OR RURAL HOSPITAL LOCATION INFLUENCE RISK FACTORS AND INCIDENCE RATE OF 30-DAY READMISSION FOR CONGESTIVE HEART FAILURE IN THE UNITED STATES?

Michael Andryka¹; Ron T. Varghese¹; Gilbert-Roy B. Kamoga²; Khaled Khasawneh¹; Neal Mehta¹. ¹White River Health System, Batesville, AR; ²White River Medical Center, Batesville, AR. (Control ID #3185559)

BACKGROUND: Congestive Heart Failure (CHF) admissions continue to rise with nearly 1 Million hospitalizations annually [1]. Furthermore, previous literature suggests that hospital characteristics such as location affect CHF hospitalization outcomes [2]. We sought to determine the 30-day all-cause readmission rate for adults (age ≥ 18) admitted with a principal diagnosis of CHF and compare the risk factors for readmission at urban and rural hospitals.

METHODS: We utilized Agency of Healthcare Research and Quality's (AHRQ) 2014 Nationwide Readmission Database which includes 14.9 Million discharges across 22 states to identify admissions with a principal diagnosis of CHF using ICD-9 codes (402.01, 402.11, 402.91, 404.01, 404.11, 404.03, 404.13, 404.91, 404.93 and 428.XX). Applicable admissions were all adults (age ≥ 18) with an index hospitalization discharge between January 1 to November 30, 2014. Patients who died during index admission and those with missing covariates were excluded. Rural and Urban classification was determined using the 2013 NCHS Urbal-Rural Classification Scheme. All-cause readmissions within 30-days of an index admission were analyzed. Statistical analysis was completed with Stata 15 (StataCorp, College Station, TX) with p-values < 0.05 considered statistically significant. A univariate and multivariate analysis of data collected was completed using

both odds ratio and chi square tests for significance. Predictors for readmission were determined using a multivariate logistic regression model following sequential step-wise elimination of covariates including demographics, comorbidities, hospital characteristics, length of stay (LOS) for index admission, and the modified Elixhauser Comorbidity Index.

RESULTS: A total of 389,466 patients met criteria for inclusion. Of which, there was 85,831 readmissions (overall rate 22.03%) within 30-days of the index admission. Index admission to an urban hospitalization had a readmission rate of 22.22% compared to 20.94% from rural hospitals ($p < 0.001$). Multivariate analysis showed that admissions to rural and urban hospitals each had a higher likelihood of readmission if they were admitted on the weekend, any disposition other than "routine," adults < 65 , longer LOS, renal failure comorbidity present and admitted to a medical service. In addition, Medicaid as a payer increased the odds for readmission at urban hospitals.

CONCLUSIONS: Almost 1 in 4 patients discharged with a principal diagnosis of CHF will be readmitted within 30 days. Index admissions to urban hospitals have a higher readmission rate than rural hospitals, but the risk factors appear to be similar. Further investigation is necessary to elucidate the reasons for the disparity in readmission rates between urban and rural hospitals, which may prove useful in developing interventions for populations at risk to reduce future morbidity and mortality. DON'T JUST DO SOMETHING, SIT THERE! ASSESSING THE IMPACT OF SITTING AT THE BEDSIDE ON PATIENTS' SATISFACTION WITH THEIR DOCTORS

Anna K. Donovan¹; Carla L. Spagnoli¹; Scott D. Rothenberger²; Raquel Forsythe¹; Jennifer Corbelli¹. ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA. (Control ID #3182767)

BACKGROUND: Improving patient satisfaction remains an important yet elusive endeavor for academic medical centers. One study demonstrated that hospitalist attending physicians in a non-teaching hospital had higher-rated communication skills when sitting compared to standing at the bedside during rounds¹. It is unclear whether these data can be applied to resident-led multidisciplinary team rounds, during which 7-8 providers round together. We hypothesized that if resident team leaders sat during morning rounds that patient satisfaction would improve without impacting rounding efficiency.

METHODS: We performed a cluster-randomized trial with crossover in which internal medicine (IM) and surgery residents served as their own controls. Each resident team leader (IM N=18; Surgery N=8) was assigned to sit or stand on a chair at the bedside during alternating weeks in May and June of 2018. Research assistants administered electronic surveys to 5 randomly selected patients per team per week for the study period of 8 weeks. In addition, all IM interns and residents (N=54) from participating teams were invited to complete a post-rotation survey about their perceptions of sitting vs. standing during rounds.

RESULTS: A total of 18 IM and 8 surgery resident team leaders participated. Surveys were collected from 583 patients. There was no statistically significant difference in patient perception of physician skill in giving complete information, using plain language, showing interest in patients and their problems, or giving patients time to ask questions (all $p > 0.05$). Results from IM and surgery did not differ. IM residents (response rate 80%) felt that rounding duration did not differ. Most indicated that sitting at the bedside was already their standard practice.

CONCLUSIONS: When randomizing medicine and surgery residents to sit or stand during team rounds, we found no difference in patient perceptions of physician communication. While sitting positively impacted attending hospitalists' patient-rated communication skills when rounding alone¹, this was not replicated with resident-led team rounds. We suspect that one member sitting, while all others stand, is not sufficient to impact the patients' perception of the entire encounter. Further, patients rated resident communication highly in both groups, so a ceiling effect may have prevented us from detecting any

difference. We speculate that sitting during one-on-one patient encounters (e.g. initial history-taking, breaking bad news), rather than team-based encounters, may have greater impact in teaching hospitals. Significance: Standing was non-inferior to sitting during rounds. Our results suggest that initiatives to optimize patient communication and satisfaction in teaching hospitals should be focused elsewhere. References: 1. Merel et al, JHM, 2016.

ECONOMIC OPPORTUNITY, AUTOMOTIVE PLANT CLOSURES, AND DRUG OVERDOSE MORTALITY: A QUASI-EXPERIMENTAL ANALYSIS

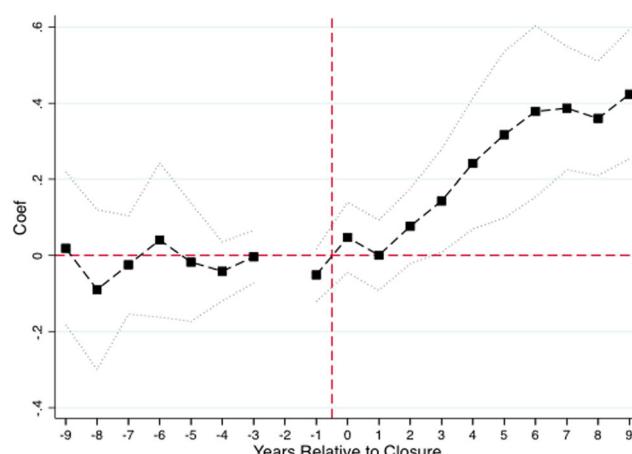

Atheendar Venkataramani¹; Elizabeth Bair². ¹University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA. (Control ID #3185703)

BACKGROUND: There is considerable debate over the role of economic factors in driving rising drug overdose mortality in the U.S. Recent theories suggest that drug overdose mortality may arise as a result of fading economic opportunities. However, standard economic measures, such as unemployment rates, explain little of the variation in drug overdose mortality. We examined the effects of U.S. automotive plant closures in the 2000s and onward. Automotive plant closures are salient shocks to economic opportunity that can shift future expectations around economic opportunity.

METHODS: Our primary outcome were annual, county-level, age-adjusted drug overdose mortality rates for 20-64 year old adults for the period 1999-2015 (obtained from the CDC). We identified all automotive plants in operation in 1999, whether they closed, and the year of closure. We defined exposure to automobile plant closures at the commuting zone-level, which are groups of counties where people live and work. The sample of interest consisted of counties with high shares of manufacturing workers. We used a quasi-experimental, event-study approach, comparing mortality rates in each individual year before and after a plant closure in that commuting zone to drug overdose mortality rates in counties in commuting zones where plants remained open, adjusting for county and year fixed effects. As a falsification test, we estimated the same model for non-manufacturing counties.

RESULTS: Our sample included 120 manufacturing counties in 39 commuting zones. Drug overdose mortality rose in each year following a plant closure (Figure): by ten years drug overdose mortality rates were 42% (95% CI: 25%, 59%) higher in closure vs. non-closure counties. Both sets of counties followed similar trends prior to plant closures and we found null estimates for non-manufacturing counties. The findings were driven by men, and not explained by differential migration rates.

CONCLUSIONS: Automotive plant closures had substantial effects on drug overdose mortality, explaining over 35% of the overall rise in the study counties between 1999-2015. We have currently obtained restricted mortality data to examine differences across age, gender, race, and education groups.

Event study model estimates

EFFECT OF A SCORING RUBRIC ON THE REVIEW OF SCIENTIFIC MEETING ABSTRACTS

Nia S. Mitchell¹; Kelly Stolzmann²; Jolie B. Wormwood^{3, 4}; Lauren V. Benning¹; Amy Linsky^{2, 2}. ¹Duke University, Durham, NC; ²VA Boston Healthcare System, Boston, MA; ³Bedford VA Medical Center, Bedford, MA; ⁴University of New Hampshire, Durham, NH. (Control ID #3184121)

BACKGROUND: Rubrics provide guidance for objective measurement of performance to decrease or eliminate subjective judgement. In 2014-2016, the Society of General Internal Medicine (SGIM) Annual Meeting scored scientific abstracts based upon four criteria: 1) importance of research question; 2) strength and appropriateness of methods; 3) validity of conclusions; and 4) clarity and concision. Reviewers were instructed to score each criterion from 1 - 7 (1 = lowest and 7 = highest), with little other guidance. The SGIM 2017 Annual Meeting program committee renamed the last criterion "quality of writing" and added detailed descriptions for each score within each criterion to provide more guidance for reviewers. The purpose of the current study is to estimate the effect of the standardized scoring rubric on the use of the entire range of scores and on reliability between reviewers.

METHODS: We evaluated scores for all abstracts submitted to SGIM annual meetings pre-rubric (2014-2016) and post-rubric (2017-2018). For each abstract, we calculated a mean and standard deviation across reviewers for each of the four individual criteria scores and the composite score (i.e., the average of the four criteria scores). We used general linear mixed modeling, nesting reviewers within abstracts, to determine if there was a difference in mean criteria and composite scores by year. Intraclass correlation coefficients (ICC) estimated inter-reviewer agreement.

RESULTS: There were 3,523 abstracts with 22,242 submitted reviews. The Table indicates the number of abstracts submitted, total number of reviews, mean (SD) number of reviewers per abstract, the mean (SD) of the composite scores, and ICCs in each of the five years. Composite scores in pre-rubric years were statistically significantly greater than composite scores in post-rubric years (5.0 pre-rubric vs. 4.8 post-rubric; p<0.0001). Repeat analyses for each of the four criteria similarly demonstrated similar statistically significant differences pre- and post-rubric (p<0.0001). There was no apparent difference in ICCs between pre-and post-rubric years.

CONCLUSIONS: A detailed scoring rubric successfully shifted scores closer to the mid-point of the scoring range, but it did not increase inter-reviewer reliability. Objective evaluation of abstract submissions is an important component to ensure the rigor and quality of the information selected for presentation. Efforts should continue to refine and use tools such as rubrics to improve the scoring of abstracts.

EFFECT OF A SPECIALTY-INITIATED E-CONSULT ON PROVIDER UNLEARNING AND PSYCHOLOGICAL REACTANCE IN DE-IMPLEMENTATION OF A LOW-VALUE MEDICATION FOR COPD

Christian D. Helffrich¹; Toral J. Parikh³; Laura Feemster⁵; Seppo Rinne²; Renda S. Wiener²; Barbara Majerczyk¹; Edmunds M. Udris⁴; David Au¹. ¹VA Puget Sound Healthcare System, Seattle, WA; ²Edith Nourse Rogers Memorial VA, Bedford, MA; ³Puget Sound VA Healthcare System, Seattle, WA; ⁴VA Puget Sound Health Care System, Seattle, WA; ⁵VA Puget Sound/University of Washington, Seattle, WA. (Control ID #3178515)

BACKGROUND: Learning health systems need to reduce low-value care as well as increase high-value care. One approach is to utilize specialists to engage at a population health level for patients in primary care. However, primary care providers (PCP) may feel their autonomy is threatened if specialists deliver unsolicited recommendations. We tested a proactive e-consultation to target low value practices among patients with chronic obstructive pulmonary disease (COPD). We sought to understand the effect of the e-consult on PCP unlearning of ineffective care for patients with mild to moderate COPD and psychological reactance to receipt of the e-consult.

METHODS: Attending PCPs at 13 VHA primary care clinics were surveyed prior (n=138) and after (n=137) the e-consult intervention as part of a

provider-level clustered randomized trial. The goals of the e-consult were to de-implement guideline-discordant use of inhaled corticosteroids (ICS) and improve safety. Intervention PCPs received a proactive e-consult with an unsigned order reflecting pulmonologist recommendations. Control PCPs received no specialist input. We assessed whether e-consults promoted unlearning of overuse of ICS by increasing awareness of ICS harms and evidence for effectiveness of substitute medications (long-acting bronchodilators, LABD), and if e-consults had the unintended effect of causing irritation and skepticism (i.e., psychological reactance).

RESULTS: Surveys were completed by 26 intervention and 20 control PCPs at baseline and 24 intervention and 24 control PCPs at follow-up (34% and 35% response rates respectively). The proportion of PCPs who correctly agreed that LABD were effective in reducing COPD exacerbations increased by 30% for intervention PCPs (42% at baseline to 72% at follow-up) vs. 3% for control PCPs (55% to 58%). The proportion who correctly agreed that ICS results in higher risk of pneumonia increased by 17% for intervention PCPs (50% to 67%) vs. declining by 2% for control PCPs (60% to 58%). Finally, the proportion who incorrectly agreed that LABD use has higher risk of cardiovascular events relative to ICS decreased by 8% for intervention PCPs (58% to 50%) vs. increasing by 19% for control PCPs (36% to 55%). Follow-up surveys asked PCPs how they felt when receiving information and advice about reducing use of ICS for patients with COPD. 25% of intervention PCPs and 4% of controls felt irritated or annoyed. No PCPs felt angry. 8% of intervention PCPs and 0% of controls reported criticizing the information. 21% of intervention PCPs and 13% of controls could think of points that go against efforts to reduce ICS use among patients with COPD. Finally, 17% of intervention PCPs and 0% of controls reported skepticism of efforts to reduce ICS use among patients with COPD.

CONCLUSIONS: We found evidence of unlearning: intervention PCPs had increased awareness of ICS risks and of LABD as effective alternatives. However, we found some evidence of reactance such as annoyance, counter-arguing and skepticism.

EFFECT OF A WIDESPREAD IMPLEMENTATION OF A STRATEGY USING CARDIOVASCULAR RISK STRATIFICATION AND PRACTICE COACHING ON HIGH RISK ADULT PATIENTS RECEIVING CARE IN SMALL NORTH CAROLINA PRACTICES

Samuel Cyker¹; Michael Pignone²; Thomas C. Keyserling³; Darren Dewalt¹; Crystal W. Cene¹; Justin G. Trogdon⁴. ¹University of North Carolina, Chapel Hill, NC; ²Dell Medical School, Austin, TX; ³UNC-Chapel Hill, Chapel Hill, NC; ⁴University of North Carolina at Chapel Hill, Chapel Hill, NC. (Control ID #3185185)

BACKGROUND: Cardiovascular disease (CVD) remains the leading cause of death in the U.S. and is particularly devastating in North Carolina (NC) counties associated with the "Stroke Belt". Despite this outlook, adoption of new evidence remains slow. An example of this is use of the November 2013 American College of Cardiology (ACC) guidelines on cholesterol management which include 10-year ASCVD risk calculation. Barriers such as poor capability of certified electronic health records (EHRs) to automate risk scores and to measure guideline adherence persist. Heart Health Now (HHN) is an AHRQ-sponsored initiative designed to evaluate the effect of risk stratification, practice facilitation, and quality improvement (QI) techniques on CVD risk for adults served by small, North Carolina primary care practices. In this report, we assess the impact of the intervention on ASCVD 10-year risk for patients found to be high risk at baseline.

METHODS: We conducted a pre-post assessment of ASCVD risk for high risk patients that were identified using a CVD population management dashboard. In addition to the dashboard, the intervention consisted of onsite practice facilitation over 12 months to help develop QI strategies and workflows that serially engage high risk patients. Risk reduction approaches included statin prescribing for patients defined by the 2013 ACC guidelines, aspirin prescribing for individuals < 60 yrs. old with ASCVD 10-year risk > 10%, and hypertension treatment. Tobacco cessation was also advised but did

not factor into post-intervention calculations. Regression analyses using patient characteristics and rural location were performed to identify factors more strongly associated with risk reduction in the study population.

RESULTS: A total of 437,556 patients in 219 small NC primary care practices received ASCVD risk scores and 183,346 (41.9%) had a calculated 10-year risk > 10%. 36,520 were associated with practices that did not complete data submission for the full intervention yielding 146,826 available for analysis. 66% of these patients were White, 24% Black, 3% Hispanic, 54% male, and 52% of rural residence. At baseline, the mean ASCVD risk score for the high risk group was 23.6% (SD +/- 12.8%). After the intervention the mean score for this group was 18.1% (SD +/- 11.7%). 52.2% of high risk patients experienced risk score reductions. In regression analysis, younger patients (OR 1.1, 95% CI 1.08 - 1.15), Blacks (OR 1.2, 95% CI 1.18 - 1.26), and rural residents (OR 1.3, 95% CI 1.27 - 1.34) benefited a little more from the intervention.

CONCLUSIONS: A one-year intervention utilizing CVD risk-stratification coupled with practice coaching resulted in significant risk reductions for a large population of high risk patients cared for by small primary care practices. These results suggest that informatics support and practice facilitation can strongly drive the use of new evidence to, specifically, reduce CVD risk and, generally, to promote health and improved outcomes.

EFFECT OF MANDATED BREAST DENSITY REPORTING LEGISLATION ON WOMEN'S AWARENESS AND KNOWLEDGE OF BREAST DENSITY

Kelly A. Kyanko¹; Jessica R. Hoag²; Susan Busch²; Jenerius Aminawung³; Xiao Xu²; Ilana B. Richman²; Cary Gross⁴. ¹NYU School of Medicine, New York, NY; ²Yale University, New Haven, CT; ³Yale University School of Medicine, New Haven, CT; ⁴Yale School of Medicine, New Haven, CT. (Control ID #3182670)

BACKGROUND: To date, 35 states have enacted dense breast notification (DBN) laws mandating that mammogram reports include language informing women of risks related to dense breast tissue. We conducted a nationally representative survey to determine the impact of these laws on women's awareness of breast density, knowledge of its association with the risk of breast cancer and sensitivity of mammography, and anxiety around breast cancer screening.

METHODS: Internet survey conducted in 2018 with participants in the GfK KnowledgePanel®, a probability-based online research panel designed to be representative of the U.S. population. The sample included 2,539 English-speaking US women aged 40 to 59 years without a personal history of breast cancer who had ever had a mammogram in their lifetime.

RESULTS: Enrollment was closed when a predetermined number of panelists screened in, resulting in a completion rate of 68.2%. Overall, 41.3% of women reported that they were informed of having dense breasts. A significantly greater proportion of women residing in DBN states were informed of having dense breasts as compared to women residing in non-DBN states (43.6% versus 32.7%, p <0.01; adjusted analyses OR 1.74, 95% CI: 1.37-2.22). Only 23.0% of women overall knew of the increased risk of breast cancer with dense breasts, with no significant difference between women in DBN states and non-DBN states. Similarly, 68.0% of women correctly answered that dense breasts make it more difficult for mammography to detect cancer, with no significant difference seen by residence in a DBN state. There was also no association between residing in a DBN state and reporting breast cancer-related anxiety.

CONCLUSIONS: In a large nationally representative survey, we found that women living in states with mandated breast density reporting laws were more likely to be aware of having dense breasts. However this was not accompanied by an increase in knowledge that dense breasts are associated with a higher risk of breast cancer and limit the ability of mammography to detect cancer. Improving readability and understandability of notification language around the clinical implications of dense breasts, or other forms of educational efforts such as mass media, may help meet this goal. Efforts may

also best be directed toward informing conversations between women and their providers, such as additional research to clarify the benefits and harms of supplemental screening and tools to engage and educate women.

EFFECT OF MARYLAND BEHAVIORAL HEALTH HOMES ON CANCER SCREENING IN WOMEN WITH SERIOUS MENTAL ILLNESS

Karly A. Murphy¹; Gail L. Daumit^{1, 2}; Elizabeth Stone¹; Sachini Bandara²; Alene Kennedy-Hendricks²; Craig E. Pollack^{1, 2}; Beth McGinty^{2, 2}. ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Control ID #3184170)

BACKGROUND: People with serious mental illness (SMI) die 10-20 years earlier than the general population, primarily due to physical health conditions; cancer is the second leading cause of death. Behavioral health homes (BHHs), which integrate primary care into specialty mental health settings, have proliferated recently with the goal to improve management and care coordination of physical health. This study sought to evaluate the effect of the Maryland Medicaid BHH program on preventative cervical and breast cancer screening in women with SMI.

METHODS: We used Maryland Medicaid administrative claims data from October 1, 2012-December 31, 2016. We included 6,059 women between ages 21-64 years with SMI, who participated in a psychiatric rehabilitation program (PRP) which indicates significant functional impairment as a result of mental illness, and were continuously enrolled in Medicaid during the study period. Of these, 1,408 women were BHH participants, and 4,651 were non-BHH participants and served as the comparison group. In one year intervals, we measured whether women ages 21-64 years received pap smears or women ages 50-64 years received screening mammography. For our analysis, we used marginal structural modeling with inverse probability treatment weighting applied to person-time periods. This approach allowed us to accommodate rolling enrollment of participants into a BHH and to adjust for baseline covariates (age, race, psychiatric diagnosis) and time-varying covariates (residence, disability, substance use, managed care organization, comorbidity, PRP characteristics). We used logistic regression to estimate the effect of BHH enrollment on cancer screening and the predicted probability of receiving screening.

RESULTS: Among 6,059 women in the study, the mean age was 41.1 years (SD=11.2) with 58.1% black race, 32.7% with schizophrenia and 55.1% with bipolar disorder, 24.8% with substance use disorder, and 57.3% with disability. The predicted annual cervical cancer screening rate was 32.6% for women enrolled in a BHH and 29.3% for women not enrolled in a BHH after adjustment for baseline and time-varying covariates. The predicted annual breast cancer screening rate was 28.5% for women enrolled in a BHH and 24.3% for women not enrolled in a BHH after adjustment for baseline and time-varying covariates. Women who were enrolled in a BHH were 27% (adjusted Odds Ratio [aOR] 1.27, 95% CI 1.04-1.55) more likely to receive pap smears and 17% (aOR 1.17, 95% CI 1.04-1.31) more likely to receive mammography.

CONCLUSIONS: Maryland's Medicaid BHH program increased cancer screenings in women with SMI. However, annual cancer screening rates among the SMI population remain lower than annual screening rates in the general population (cervical cancer 42%, breast cancer 43%). This suggests that integrated care models, such as BHHs, can improve preventative care for the SMI population, but future work is needed to improve health equity between SMI and non-SMI populations.

EFFECT OF PRACTICE FACILITATION ON PREVENTIVE CARDIOLOGY IN PRIMARY CARE: A PRACTICE-RANDOMIZED, COMPARATIVE EFFECTIVENESS STUDY

Yaw A. Peprah¹; Tiffany Brown¹; Jody Ciolino²; Randy Hountz³; Karen Iversen⁴; Linda Murakami⁵; Jennifer Potempa⁶; Luke Rasmussen²; Theresa L. Walunas²; Jesi Wang⁷; Chen Yeh²; Abel Kho¹; Stephen Persell¹.

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Northwestern University, Chicago, IL; ³Purdue Healthcare Advisors, West Lafayette, IN; ⁴AllianceChicago, Chicago, IL; ⁵American Medical Association, Chicago, IL; ⁶Telligen, Oak Brook, IL; ⁷MetaStar, Madison, WI. (Control ID #3184154)

BACKGROUND: Healthy Hearts in the Heartland (H3) is a quality improvement (QI) program focused on preventive cardiology in primary care practices in the Midwest using practice facilitation. Clinical targets included the "ABCS" quality measures: (A) Aspirin/antiplatelet therapy for ischemic vascular disease, (B) Controlling High Blood Pressure, (C) Statin Therapy for the Prevention and Treatment of Cardiovascular Disease, and (S) Tobacco Use: Screening and Cessation Intervention.

METHODS: Practices from Illinois, Indiana, and Wisconsin were randomized to 12 months of facilitator support aimed at implementing either point-of-care (POC) QI strategies alone or POC plus population management (POC+PM) strategies. Randomization was done in four waves, with a modified constrained process used to ensure within-wave balance. Practices in the POC arm received coaching and encouragement to select improvement strategies to address care at office visits. Practices in the POC+PM arm received coaching to use POC approaches and population health management strategies. Practice surveys included items about EHR functionality, perceived ability to address barriers to QI, Change Process Capability Questionnaire (CPCQ) summary score for preventive cardiology improvement, and each practice's patient population. Quality measures were collected in three ways: directly from EHRs using Physician Quality Reporting System (PQRS) measures, using popHealth (an open-source quality measure database and reporting engine using data exported from the practices' EHRs), or manual chart review (when PQRS and popHealth not possible). Primary analyses compared the performance on each ABCS measure at baseline and 12 months among all practices using a paired t-test. We then compared the mean values of the ABCS measures at 12 months across study arms controlling for baseline values.

RESULTS: 2281 practices were assessed; 583 were ineligible; 1472 declined, would not schedule a recruitment visit or were unreachable; 226 practices were enrolled and randomized. Study arms were balanced across measured baseline practice characteristic. 179 practices contributed follow-up 12-month data. Overall, performance on ABCS measures was greater at 12 months compared to baseline: (A) 4% (95% CI, 2 to 6), (B) 4% (2 to 6), (C) 5% (3 to 7), (S) 5% (2 to 7), P<0.001 for each. Over 12 months, the adjusted difference-in-differences for the POC+PM arm versus POC was: (A) 2% (-2 to 5), (B) -1% (-4 to 3), (C) 3% (0 to 7), and (S) 2% (-2 to 6); p >0.05 for all. CPCQ improved slightly overall, mean change 0.30 (0.09 to 0.51) but did not differ across study arms.

CONCLUSIONS: Among participating practices, practice facilitator-led QI was associated with modest improvements in preventive cardiology measures, but we did not find convincing evidence that adding the option to implement population management approaches was superior to point-of-care strategies alone.

EFFECT OF SOCIODEMOGRAPHIC FACTORS ON UPTAKE OF A PATIENT-FACING INFORMATION TECHNOLOGY FAMILY HEALTH HISTORY RISK ASSESSMENT PLATFORM

BACKGROUND: Patient-facing family health history (FHH) based risk assessment platforms have been shown to increase identification of at-risk individuals within the general population and alter practice patterns to address at-risk individuals' needs. We sought to ascertain differences in utilization of one such tool, MeTree, across a diverse patient population. Given patients' range of experiences and comfort with IT-based health applications, knowledge of and sharing of health information between family members, health information-seeking, cultural practices, and other patient demographics, we hypothesized that differences in uptake might exist. In this paper, we report our findings regarding 1) the degree to which uptake of the intervention varied by patient demographics and 2) the impact of socio-demographics on variations in utility of the platform as measured by the quality of the data collected.

METHODS: This was a type III hybrid implementation-effectiveness trial in four diverse healthcare systems across the United States. The trial was administered almost exclusively online, including consent, baseline survey, and risk assessment completion. Subjects were any adult (age 18) scheduled for a routine primary care appointment at a participating clinic. Measures included participant demographics, personal and family health history, health literacy and information seeking. We used multi-variate logistic regression to model the effect of sociodemographic and other factors on study progression. Quality of FHH data entered as defined as relatives: 1) with age of onset reported on relevant conditions; 2) if deceased, with cause of death and 3) age of death reported and 4) percentage of relatives with medical history marked as unknown was analyzed using grouped logistic fixed effect regression.

RESULTS: 2,514 participants consented, mean age 57 and 10.4% minority. Multi-variate modeling showed progression through study stages was more likely for younger (p-value=0.005), more educated (p-value=0.004), non-Asian (p-value=0.009), and female (p-value=0.005) subjects. Those with lower health literacy or information-seeking confidence were less likely to complete the study (p-value< 0.001 and 0.03 respectively). Most significant drop-out occurred during the risk assessment completion phase. Overall, quality of FHH data entered was high: relatives' condition's age of onset reported 87.9%, relative's cause of death 85.6% and age of death 93.8%, and relative's medical history marked as unknown 19.8% of the time.

CONCLUSIONS: A demographically diverse population was able to complete an IT-based risk assessment but there were differences in attrition by sociodemographic factors particularly related to age and education level. More attention should be given to ensure end-user functionality of health IT and leverage electronic medical records to lessen patient burden.

EFFECT OF THYROID HORMONE REPLACEMENT ON FATIGABILITY IN OLDER ADULTS WITH SUBCLINICAL HYPOTHYROIDISM: A RANDOMIZED PLACEBO CONTROLLED TRIAL

Mirah J. Stuber¹; Elisavet Moutzouri^{1, 2}; Martin Feller^{1, 2}; Cinzia Del Giovane¹; Manuel R. Blum^{2, 3}; Nancy W. Glynn⁴; Douglas Bauer⁵; Jacobijn Gussekloo^{6, 6}; Vera J. McCarthy⁷; Patricia M. Kearney⁷; Drahomir Aujesky²; Rudi G. Westendorp⁸; David J. Stott⁹; Nicolas Rodondi^{1, 2}. ¹University of Bern, Bern, Switzerland; ²Inselspital, Bern University Hospital, Bern, Switzerland; ³Stanford University School of Medicine, Stanford, CA; ⁴University of Pittsburgh, Pittsburgh, PA; ⁵University of California, San Francisco, CA; ⁶Leiden University Center, Leiden, Netherlands; ⁷University College Cork, Cork, Ireland; ⁸University of Copenhagen, Copenhagen, Denmark; ⁹University of Glasgow, Glasgow, United Kingdom. (Control ID #3185049)

BACKGROUND: Global fatigue is one of the most commonly reported symptoms in subclinical hypothyroidism (SHypo) and one of the main reasons for prescribing levothyroxine. The recent TRUST trial done by our group indicated no benefit on global fatigue from levothyroxine replacement in SHypo. Given that the treatment of SHypo remains controversial, we analyzed the effect of levothyroxine replacement in patients with SHypo

using a new fatigability scale that measures both physical and mental domains. Perceived fatigability anchors tiredness to a set of activities and has been shown to be a more sensitive measure than global fatigue.

METHODS: The TRUST trial was a double-blind, randomized, placebo-controlled, parallel-group trial involving adults aged 65 and diagnosed with SHypo defined as the presence of persistently elevated TSH levels (4.6–19.9 mU/L) with free thyroxine within the reference range. The present substudy on fatigability included participants from Switzerland and Ireland. Our outcome was the between-group difference in perceived physical and mental fatigability after twelve months using the Pittsburgh Fatigability Scale (PFS), a 10-item self-administered questionnaire, that measures both physical and mental fatigability (scores range from 0 to 50, higher score=higher fatigability). Multivariate linear regression models were adjusted for levothyroxine starting dose, sex, site and baseline scores in a modified intention to treat population.

RESULTS: This study included 230 participants (mean age: 73.4 years; 44.4% female). The mean \pm SD TSH was 6.2 ± 1.9 mIU/L at baseline and after 1 year decreased to 3.1 ± 1.3 mIU/L in the levothyroxine group vs. 5.3 ± 2.3 mIU/L in the placebo group ($p<0.001$). At baseline, mean physical PFS score was 14.7 ± 9.3 in levothyroxine group and 11.1 ± 9.1 in placebo group; mean mental PFS score was 7.4 ± 8.0 and 5.1 ± 6.9 , respectively. The mean physical PFS score at 12 months (adjusted for baseline score) was 13.7 ± 0.7 for levothyroxine group and 13.6 ± 0.7 for placebo group ($p=0.88$); mean mental PFS score was 5.5 ± 0.6 and 6.5 ± 0.7 , respectively ($p=0.26$). After adjustment for covariates, we found no significant difference in the mean follow up scores at 1 year after levothyroxine replacement on perceived physical fatigability (between-group difference = 0.2; 95% confidence interval [CI]= -1.8 to 2.1; $p=0.88$) nor on mental fatigability (between-group difference -1.0; 95% CI= -2.8 to 0.8; $p=0.26$).

CONCLUSIONS: Our substudy extended the TRUST trial's findings by examining the novel constructs of physical and mental fatigability. Levothyroxine replacement in SHypo was not associated with change in physical fatigability nor with change in mental fatigability. Therefore, fatigue does not seem to be a good indication to prescribe levothyroxine in SHypo.

EFFECTIVE DEPRESSION MANAGEMENT IN A COLLABORATIVE CARE MODEL: COMPARING RESIDENTS AND ATTENDING PHYSICIANS IN AN ACADEMIC GENERAL MEDICINE CLINIC.

Jessica Ristau^{1, 2}; Celia P. Kaplan²; Douglas Bauer²; Mitchell D. Feldman²; Maki Aoki²; Rosemary Lam²; Maria E. Garcia². ¹UCSF, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA. (Control ID #3176032)

BACKGROUND: The Collaborative Care Model (CCM) is effective for depression care. Yet there is limited information regarding CCM implementation in academic centers. This study examines whether patients with resident primary care physicians (PCPs) achieve similar outcomes as those with attending PCPs.

METHODS: This prospective cohort study assessed potential differences in a combined resident and attending academic general medical practice between PCP type (resident versus attending) and depression identification and follow-up. CCM included multidisciplinary team-based engagement including a psychiatrist consultant, social worker and behavioral health assistant using systematic universal screening, validated clinical rating scales and population-based registries to facilitate active management with the PCP. The study included all patients seen from October 2017 to October 2018 with a PHQ9 >10 and a second PHQ9 >0 at least 6 weeks later (N=149 of >6,000 patients screened). We used the electronic medical record to assess primary outcomes (PHQ9<10, PHQ9 decrease by 50%, and/or remission), and secondary outcomes (referrals to psychotherapy and/or antidepressant prescriptions) at the end of the study period.

RESULTS: The population was diverse (69% non-white), primarily English-speaking (92%), had mostly public insurance (71%), and had a high

medical complexity score (62%, clinic-specific index that includes chronic illnesses, medications, online messages). Patients with resident PCPs (n=23) were younger (age 45 vs. 56, $p<0.001$) with higher rates of Medicaid (20.3% vs. 7.8%, $p=0.025$), compared to those with attending PCPs (n=18). At baseline, patients averaged PHQ9 score 15.8, 14 visits in the health care system per year, and time between PHQ9 scores was 6.2 months, with no difference by PCP type. Patients with an attending PCP were more likely to improve by all metrics (see Table 1), despite no differences in the secondary outcomes (therapy referrals and antidepressant prescriptions). Notably, the patients with attending PCPs were more likely to have their initial positive screening visit with their PCP (81.1% for attendings vs. 62.7% for residents, $p=0.012$) rather than a covering provider.

CONCLUSIONS: In a diverse urban academic clinic, the depression CCM demonstrated lower effectiveness for patients of resident PCPs compared to those with attending PCPs despite similar process measures.

EFFECTIVE TEACHERS OF INVASIVE BEDSIDE PROCEDURES: A MULTI-INSTITUTIONAL QUALITATIVE STUDY

Diana J. Kelm¹; Jennifer L. Ridgeway¹; John T. Ratelle¹; Adam P. Sawatsky¹; Alexander S. Niven¹; Anna K. Brady²; Jakob McSparron⁴; Margaret Hayes³; Kannan Ramar¹; Thomas J. Beckman¹. ¹Mayo Clinic, Rochester, MN; ²Oregon Health and Science Center, Portland, OR; ³Beth Israel Deaconess Medical Center, Boston, MA; ⁴University of Michigan, Ann Arbor, MI. (Control ID #3178534)

BACKGROUND: Invasive bedside procedures (IBPs) in the intensive care unit (ICU) are often performed urgently, putting patients at substantial risk. Complications from IBPs are preventable and related to operator proficiency. Residents receive IBP education, yet there is limited research on what constitutes an effective IBP teacher. We conducted a multi-institutional qualitative study of Pulmonary and Critical Care Medicine (PCCM) faculty and fellows to better understand their perspectives on the characteristics of effective IBP teachers.

METHODS: Focus groups (FGs) were conducted at Mayo Clinic and Oregon Health and Sciences University. Two FGs were held with fellows and two with faculty. FGs were facilitated by a trained investigator, audio-recorded, and transcribed verbatim for analysis. Themes were identified inductively and then compared against constructs from social and situated learning theories. Data was analyzed between and across professional groups. Qualitative research software (NVivo, QSR International) was used to facilitate data organization and create an audit trail of the analysis process. A multidisciplinary research team was engaged to minimize interpretive bias.

RESULTS: Seventeen fellows and eighteen faculty participated. Inductive analysis revealed 3 themes related to attributes of effective IBP teachers: observed behaviors, personal characteristics, and influence on the learning environment. Observed behaviors (representative quotes) included leading pre-procedure huddles to assess learner experience with IBPs and defining expectations ("Assess the learner... to figure whether they can proceed"), along with debriefing and providing feedback ("A good procedural teacher gives feedback after the procedure ... reinforcing what you liked ... and what could make it go more smoothly"). Personal characteristics included procedural competency, calm demeanor, and demonstrating trust ("I think it's just personality ... some people seem to be composed." "They stay calm ... especially in high-pressure situations."). Important environmental factors were creating safe learning climates, reducing distractions, and focusing on the procedure ("The best procedural teacher ... no matter what was going on outside ... remained focused," "In a crowded room and intense situation ... I literally whisper in the learner's ear, *use the needle like this*").

CONCLUSIONS: PCCM fellows and faculty cited a range of personal and behavioral characteristics of effective IBP teachers, such as checking in with residents and debriefing on procedures;

remaining calm and providing encouragement; and creating safe environments and ensuring focus on IBPs. The potential risk of complications during IBPs underscores the need for procedural competency, yet this study found a notable emphasis on the interpersonal, as opposed to technical, aspects of successful IBP teachers. These findings should inform future curricula on teaching IBPs in the ICU.

EFFECTIVENESS AND COST-EFFECTIVENESS OF MAILED FECAL IMMUNOCHEMICAL TESTS FOR COLORECTAL CANCER SCREENING IN A SAFETY NET HEALTH SYSTEM

Brennan Lanier¹; Nicole Kluz¹; Charu Juneja¹; Todd Olmstead²; Michael Pignone^{1, 1}. ¹Dell Medical School, Austin, TX; ²LBJ School of Public Affairs, Austin, TX. (Control ID #3184162)

BACKGROUND: Colorectal cancer screening rates are suboptimal, especially in uninsured and low-income patients served in Federally Qualified Health Centers (FQHC). Mailed Fecal Immunochemical Testing (FIT) has been demonstrated to increase screening rates in vulnerable patients, but the optimal means of ensuring uptake and cost-effectiveness is unclear. Human-Centered Design can help improve the effectiveness of patient-directed interventions like mailed FIT. We sought to evaluate the effectiveness and cost-effectiveness of a novel mailed FIT intervention based on Human-Centered Design principles.

METHODS: Methods: As part of a larger study to implement mailed FIT in an FQHC system, we sought to test the effectiveness and cost-effectiveness of different approaches to encouraging uptake of mailed FIT. Our basic intervention consisted of a generic mailing packet that included an introductory letter in plain language, the FIT itself, easy to read instructions, and a postage-paid lab mailer, supplemented with written and text messaging reminders from the FQHC system. Our enhanced intervention was developed in collaboration with the Dell Medical School Design Institute for Health. It included simplified instructions with pictorial guidance that emphasized ease of use, a graphic redesign, enhanced packaging (cardstock pouch that allowed the FIT to be placed in the bathroom as a visual cue), and the same written and text-based reminders. We conducted multiple rounds of small tests of change to evaluate the return rate (effectiveness) of mailed FIT within 60 days. We then used modeling to examine the cost effectiveness of the standard and enhanced mailers in terms of costs per additional patient screened. Cost parameters were based on supply costs and detailed observations of labor required, valued at the wage rate. We prospectively defined a cost-effectiveness threshold for adoption of \$50 per additional patient screened.

RESULTS: Uptake of the basic mailer and reminders was 22.5% at an average cost of \$5,374 per 500-patient mailing. Uptake of the enhanced mailer was 27.5% at a cost of \$7,225 per 500-patient mailing (difference 5.0% points uptake and \$1851 costs). The cost per additional patient screened was \$47.77 for the basic intervention mailer compared with no intervention. The incremental cost-effectiveness of the enhanced mailer was \$74.05 per additional patient screened. If the unit cost of the FIT pouch could be reduced from \$2.22 to \$1.01, or if the uptake rate of the enhanced intervention was 31.8% or greater, then the enhanced mailer would become cost-effective.

CONCLUSIONS: Mailed FIT is an effective and cost-effective population health strategy for increasing CRC screening in safety net patients. As compared to the standard mailed FIT process, our enhanced mailer increases the response rate, but is not cost-effective with current unit costs. Additional testing of lower cost variants based on human-centered design is recommended as a next step.

EFFECTIVENESS AND SAFETY OF DABIGATRAN ETEXILATE IN PATIENTS WITH NEWLY DIAGNOSED ATRIAL FIBRILLATION FROM THE UNITED STATES: ANALYSIS OF THE GLOBAL REGISTRY ON LONG-TERM ORAL ANTITHROMBOTIC TREATMENT IN PATIENTS WITH ATRIAL FIBRILLATION STUDY

Alex Spyropoulos²; Brian Olshansky³; Shihai Lu¹; Gregory Y. Lip^{4, 8}; Menno Huisman⁵; Christine Teutsch⁶; Jonathan L. Halperin⁷. ¹Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT; ²The Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, New York, NY; ³University of Iowa, Carver College of Medicine, Iowa, IA; ⁴Institute of Cardiovascular Science, University of Birmingham, Birmingham, United Kingdom; ⁵Leiden University Medical Center, Leiden, Netherlands; ⁶Boehringer Ingelheim International GmbH, Ingelheim, Germany; ⁷Mount Sinai Medical Center, New York, NY; ⁸Liverpool Centre for Cardiovascular Science, University of Liverpool and Liverpool Heart and Chest Hospital, Liverpool, United Kingdom. (Control ID #3184986)

BACKGROUND: In randomized clinical trials, dabigatran etexilate (DE) has demonstrated efficacy and safety in the prevention of stroke in non-valvular atrial fibrillation (NVAF). However, long-term, real-world prospective data are limited. The Global Registry on Long-Term Oral Antithrombotic Treatment in Patients with Atrial Fibrillation (GLORIA-AF) is an ongoing, 3-phase, prospective, global registry assessing real-world data on usage and outcomes of antithrombotic treatments for stroke prevention in patients with newly diagnosed NVAF who are at a risk of stroke.

METHODS: Clinical and composite outcomes from the GLORIA-AF Phase II trial comprising baseline evaluation and 2-year follow-up for United States (US) patients taking DE 150 mg twice daily were assessed. Outcomes per 100 patient-years (95% confidence interval) were calculated. A small number of patients who were receiving DE 75 mg twice daily were excluded.

RESULTS: Of the 591 eligible patients with newly diagnosed NVAF prescribed DE 150 mg twice daily (mean age, 69.4 years; mean CHA₂DS₂-VASc score, 3.0; mean HAS-BLED score, 1.3), 590 had taken 1 DE dose. The table shows incidence rates for clinical and composite outcomes.

CONCLUSIONS: These data are the first long-term, prospectively collected real-world data of a US cohort with newly diagnosed NVAF treated with DE. The results, consistent with clinical trials, indicate a favorable benefit-risk profile of DE 150 mg twice daily in US patients with newly diagnosed NVAF.

EFFECTIVENESS OF A BRIEF INTERVENTION TO INCREASE RAPID PRIMARY CARE FOLLOW-UP AMONG AFRICAN AMERICAN PATIENTS WITH UNCONTROLLED DIABETES

Emily M. Mylhousen¹; Elizabeth A. Tolley²; Satya Surbhi¹; Patti Smith¹; Carolyn Riordan¹; James E. Bailey². ¹University of Tennessee Health Science Center, Memphis, TN; ²University of Tennessee Health Science Center, Memphis, TN. (Control ID #3185131)

BACKGROUND: Diabetes management requires primary care engagement. Without a usual source of care, patients with diabetes have higher risks of uncontrolled disease, hospitalizations, and early death. Patients in medically underserved areas (MUA) are at especially high risk for inadequate diabetes management during transitions of care. This study sought to assess: 1) feasibility of assisting hospitalized patients to obtain rapid primary care follow-up 2) effectiveness of a brief intervention to encourage rapid primary care follow-up and 3) challenges patients face in scheduling follow-up care after hospitalization.

METHODS: Three-part study of adult patients with uncontrolled diabetes including: 1) cross-sectional study— patient experience getting care, 2) pilot pragmatic randomized controlled trial— intervention to improve primary care follow-up and 3) secret shopper assessment— ease of primary care appointment making. Patients were enrolled at hospitalization to one of 3 major hospitals of a non-profit health system serving MUA in the Mid-South. Inclusions: African-American, HbA1C>8%, and >1 chronic health condition. Exclusions: pregnancy, psychiatric, or cognitive impairment. The baseline cross-sectional survey was conducted upon enrollment. All patients received pamphlet on importance of rapid PCP follow-up. The intervention group also was given an appointment within 14 days of anticipated discharge. Hold times and new patient appointment availability were recorded. Primary outcomes included self-reported PCP attendance within 7 and 14 days. Secondary outcomes included patient-reported difficulty getting needed care as well as hold times and new patient appointment availability for primary care follow-up.

RESULTS: Six African American patients with uncontrolled diabetes were enrolled in each trial arm (n=12). Characteristics: mean age 54, 67% male, 75% high school education or less, 25% with regular PCP, 66.7% with usual source of preventive and mean of 2 hospitalizations in past 6 months. Patients reported delay of care due to inability to get through on the phone (42%), inability to make appointment (50%) and long wait times (42%). 80% of primary care clinics reported new patient availability. Clinics with call centers (n=3) had long hold times (mean 14 mins, 16 secs). PCP follow-up was similar across groups—0% follow-up within 7-days, 20% within 14-days.

CONCLUSIONS: This pilot study demonstrates patients with uncontrolled diabetes in MUA have difficulty getting prompt outpatient follow-up care. Vulnerable patients commonly experience difficulty getting scheduling appointments. Hold times for scheduling PCP visits are long and serve as a barrier to rapid follow-up. We found that hospital assistance with appointment making is no panacea—assistance did not improve PCP follow-up. This study suggests that primary care capacity, accessibility, and integration with hospital networks are fundamental problems that must be addressed to adequately serve our most vulnerable patients.

EFFECTS OF A REFINED EVIDENCE-BASED TOOLKIT ON MEDICATION RECONCILIATION QUALITY AND SAFETY AT MULTIPLE HOSPITALS: RESULTS OF THE MARQUIS2 STUDY

Jeffrey Schnipper^{1, 2}; Harry Reyes Nieva^{1, 2}; Meghan Mallouk³; Amanda S. Mixon⁴; Stephanie Rennke⁵; Eugene S. Chu⁶; Stephanie Mueller^{1, 2}; G. R. Smith⁷; Mark V. Williams⁸; Toshia B. Chan School of Public Health, Boston, MA; ¹⁴SUNY Downstate Medical School, Brooklyn, NY; ¹⁵Vanderbilt University Medical Center, Nashville, TN. (Control ID #3183344)

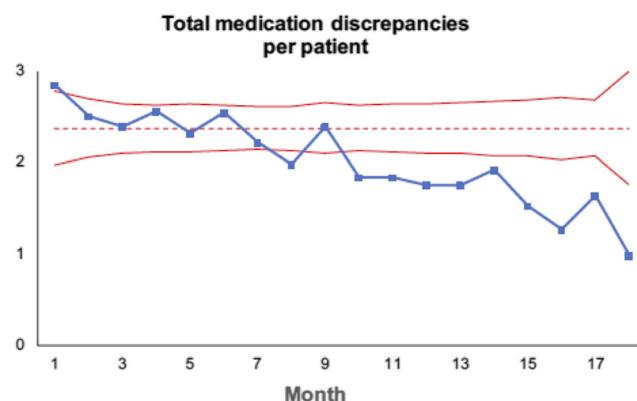

BACKGROUND: The Multicenter Medication Reconciliation Quality Improvement Study (MARQUIS1) demonstrated that a medication reconciliation best practices toolkit decreased total unintentional medication discrepancies in 5 hospitals. Incorporating lessons learned, we implemented a refined toolkit in a more diverse sample of hospitals.

METHODS: After a formal application process, we selected 18 sites to implement the revised toolkit. This quality improvement (QI) project offered 17 intervention components. One of 8 hospitalists trained in physician-mentored QI coached each site via monthly calls and 1-2 site visits during an 18-month intervention. Each site's QI team assessed local practices, identified improvement opportunities, and implemented toolkit components. The primary outcome was unintentional medication discrepancies in admission or discharge orders, measured by comparing them to a gold standard medication history taken by trained pharmacists, supplemented with medical record review. We used interrupted time-series (ITS) analysis to determine effects of the intervention over time, adjusting for baseline temporal trends. We modeled the number of discrepancies per patient using multivariable Poisson regression adjusted for patient covariates with total number of medications as a model offset and clustered by site. We also conducted on-treatment analyses to determine the effects of a patient receiving at least 1 intervention.

RESULTS: All 18 sites implemented 1 to 15 toolkit components. One site did not collect enough data to be included in analyses. The other 17 sites (4947 patients) saw a steady decline in medication discrepancy rates from approximately 3 discrepancies/patient to 1 discrepancy/patient (Figure 1). In ITS analysis, sites saw a 5% relative decrease in discrepancies/month over baseline temporal trends (adjusted incidence rate ratio 0.95 (95% CI 0.93-0.97; p<0.001). Patients who received at least 1 patient-level intervention had 53% fewer discrepancies than those who did not receive any [aIRR 0.47 (0.45-0.49); p<0.001].

CONCLUSIONS: A multicenter medication reconciliation QI initiative using a refined best practices toolkit was associated with a large reduction in unintentional medication discrepancies.

Statistical process control chart of effects of MARQUIS2 intervention on unintentional medication discrepancies

EFFECTS OF GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS VS. PLACEBO AND OTHER ANTIHYPERGLYCEMIC AGENTS IN PATIENTS WITH TYPE 2 DIABETES: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS.

Jason T. Alexander¹; Erin M. Staab¹; Wen Wan¹; Melissa Franco¹; Alexandra Knitter¹; Enkhe-Tuyaay Montgomery¹; Celeste Thomas¹; Valerie G. Press¹; Meltem Zeytinoglu¹; Elizabeth L. Tung¹

Kathryn E. Gunter¹; Sanjay Jumani¹; Brittany Bindon¹; Shari Bolen²; Nisa Maruthur³; Elbert S. Huang¹; Louis Philipson¹; Neda Laiteerapong¹. ¹University of Chicago, Chicago, IL; ²MetroHealth/Case Western Reserve University, Cleveland, OH; ³Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3180182)

BACKGROUND: Recent evidence from large randomized trials suggests that a new class of medication, the glucagon-like peptide-1 receptor agonists (GLP1RAs), may reduce mortality in addition to lowering hemoglobin A1c in patients with type 2 diabetes (T2D). Even with this evidence, treatment algorithms continue to list metformin monotherapy as first-line.¹ Understanding the magnitude of benefits of GLP1RAs compared to placebo and other antihyperglycemic agents may lead to significant changes in clinical algorithms. We quantified the effects that GLP1RAs have on hemoglobin A1c and mortality by conducting a systematic review and meta-analysis of all randomized trials of this new drug class. ¹Davies MJ, D'Alessio DA, Fradkin J, et al. Management of hyperglycemia in type 2 diabetes, 2018. A consensus report by the American Diabetes Association (ADA) and the European Association for the Study of Diabetes (EASD). *Diabetologia*. 2018 Dec;61(12):2461-98.

METHODS: We searched PubMed and Scopus (inception to March 2018) for randomized trials of at least 52 weeks duration enrolling adults with T2D that compared GLP1As with placebo or a different antihyperglycemic agent. Two reviewers independently extracted data to ensure accuracy, and differences were resolved by a third reviewer and discussion if necessary. Primary outcomes were change in hemoglobin A1c and all-cause mortality. Effect sizes and standard errors were calculated using the Hedges' g method and Mantel-Haenszel method for hemoglobin A1c and mortality, respectively. Pooled analyses with both fixed and random effect models were performed using the generic inverse variance method. Heterogeneity for each outcome was assessed with the Cochran's Q test and I² statistic.

RESULTS: A total of 31 randomized controlled trials comprising 46,912 patients were included in the primary analysis. Using a random effect model, patients who received a GLP1RA had a lower hemoglobin A1c when compared to placebo or other antihyperglycemic agent (mean effect size = -0.28, 95% CI -0.32 to -0.23), however heterogeneity was high (Cochran's Q = 144, I² = 0.79). Patients receiving GLP1RAs also had lower all-cause mortality (OR = 0.87, 95% CI 0.81 to 0.95), and results were not heterogeneous (Cochran's Q = 14, I² = 0).

CONCLUSIONS: In this systematic review and meta-analysis, patients who received GLP1RAs when compared to placebo or other antihyperglycemic agent had significantly lower hemoglobin A1c levels and mortality rates. Subsequent analyses of changes in cardiovascular risk factors, adverse events, and costs will be needed to help inform future healthcare policy decisions.

EFFECTS OF INTENSIVE PRIMARY CARE ON HIGH-NEED PATIENT EXPERIENCES: FINDINGS FROM A VETERANS AFFAIRS RANDOMIZED QUALITY IMPROVEMENT TRIAL

Donna M. Zulman^{1, 3}; Evelyn T. Chang²; Ava Wong³; Jean Yoon³; Susan E. Stockdale⁴; Michael Ong^{5, 2}; Lisa V. Rubenstein⁶; Steven Asch^{1, 3}. ¹Stanford University, Stanford, CA; ²VA- Greater Los Angeles, Los Angeles, CA; ³Palo Alto VA, Menlo Park, CA; ⁴Greater Los Angeles VA Healthcare System, Sepulveda, CA; ⁵UCLA, Los Angeles, CA; ⁶RAND and UCLA, Medford, OR. (Control ID #3184123)

BACKGROUND: Intensive primary care programs have been implemented across diverse healthcare settings to address the needs of patients with medical, behavioral, and social complexity. This study sought to determine how these programs influence patient satisfaction, perceived access, care coordination, trusting relationships.

METHODS: In 2014, the VA launched a national demonstration program to augment the Patient Aligned Care Team (PACT) medical home with PACT-Intensive Management (PIM) programs for high-need patients. Veterans in five VAs were identified based on VA-based hospitalization risk scores 90th percentile and a recent hospitalization or ED visit. A random sample were allocated to PIM between 9/1/2014 and 6/1/15; the remaining patients received usual PACT care. Patients in PIM were offered services such as health coaching, medication reconciliation, care coordination with specialists, and home visits from a dedicated team staffed by primary care providers, social workers, psychologists, nurses, and/or other support staff. We contacted 2,566 PIM and PACT patients to complete a mail survey between 6/3/16 and 12/16/16. The survey included measures of satisfaction with VA services, perceived access, care coordination, patient-centered care, having a trusted provider, and the Patient Assessment of Chronic Illness Care (PACIC). Responses were compared for PIM vs. PACT patients using multivariable logistic and mixed models with site-level fixed effects, adjusting for age, sex, race/ethnicity, education, income, functional status, marital status, living alone, social support, loneliness, and health literacy. Veterans who reported participating in PIM were also queried about their experiences with the program.

RESULTS: 759 PIM and 768 PACT patients responded to the survey (response rate 60%). Patients randomized to PIM were more likely than those in PACT to report that they have a VA healthcare provider who helps coordinate their care (AOR=1.17; P=0.031), that they were asked about their health goals (AOR=1.23; P=0.011), and that they have a VA provider whom they trust (AOR=1.31; P<0.001) and who respects them (AOR=1.17; P = 0.032). PIM patients were also more likely to report 10 out of 10 on satisfaction with primary care (AOR=1.20; P=0.017), however other effects on satisfaction and access did not achieve statistical significance. Among the 281 Veterans who reported current or previous enrollment in PIM, most agreed or strongly agreed that the team responded quickly to health concerns (80%), helped them get VA care that they needed (82%), helped them meet their health goals (70%), and improved their overall VA care (72%).

CONCLUSIONS: The VA's intensive primary care program was well-received by participants and had a positive influence on patient experiences with care coordination, trust, and provider relationships, but did not have a significant impact on most patient-reported access and satisfaction measures.

EFFECTS OF MEDICAID EXPANSION ON AVOIDABLE MORTALITY IN KENTUCKY IN COMPARISON TO NORTH CAROLINA

Maryam L. Famouri¹; Julia Rushing²; Ramon Velez¹. ¹Wake Forest Baptist Medical Center, Winston-Salem, NC; ²Wake Forest University Medical Center, Winston-Salem, NC. (Control ID #3185459)

BACKGROUND: In 2014, the Affordable Care Act (ACA) expanded Medicaid eligibility for most adults with incomes up to 138 percent of the poverty level, which resulted in large decreases in uninsured rates in both expansion and non-expansion states, especially in low income populations. Studies have indicated that Medicaid expansions prior to the ACA have led to decreases in all-cause mortality; however, the ACA Medicaid expansions' effect on health care amenable mortality is less clear. To explore this relationship, we compared health care amenable mortality rates in Kentucky, an expansion state, with North Carolina, a non-expansion state.

METHODS: All mortality data were obtained from the CDC WONDER online database, and all demographic data were extracted from the American Community Survey. We defined 2010-2013 as the pre-reform period and 2014-2016 as the post-reform period. Individuals who were not between the ages of 15-64 during the pre or post-reform period were excluded from the analysis. Demographic characteristics and health care amenable age-adjusted mortality rates were collected at the county level. The criteria for health care amenable diseases were based on a definition by

McKee and Nolte. A generalized linear model was developed for age-adjusted health care amenable mortality in both states, adjusting for demographics including median income, gender, marital status, race, unemployment rate, and other socioeconomic factors. The average age-adjusted mortality rate for the pre-intervention period (2010-2013) was also used as a covariate in the model to ensure that the comparisons were balanced beginning with the intervention period.

RESULTS: All demographic characteristics significantly varied between the two states ($p<0.05$). Between 2010-2016, age-adjusted health care amenable mortality increased by 6.25% in Kentucky, while North Carolina saw a modest decrease of 0.7% during the same time period. Crude age-adjusted mortality rate in the post-reform period in Kentucky was 184.9 per 100,000 as compared to 176.2 in the pre-reform period. Crude age-adjusted mortality in North Carolina was 148.1 per 100,000 in the post-reform period and 147.6 in the pre-reform period. In the generalized linear model, both states showed increasing age-adjusted mortality rates with time, but Kentucky had a sharper increase (188.92 to 204.13, p -value <0.0001) in comparison to North Carolina (178.61 to 181.84, p -value<0.0001) during the post-reform period.

CONCLUSIONS: This analysis suggests that the ACA Medicaid expansions either had no effect or resulted in increased mortality in the state of Kentucky. Given that age-adjusted health care amenable mortality has been steadily increasing in Kentucky since 2010, it is possible that increased insurance coverage has not provided the long-term medical management necessary to amend outcomes. We plan to conduct additional studies to better characterize the relationship between Medicaid expansion and mortality in the United States.

EFFECTS OF PATIENT-CENTERED MEDICAL HOMES TEAMWORK ON PRIMARY CARE STAFF SATISFACTION WITH CARING FOR HIGH-RISK PATIENTS

Alexis K. Huynh¹; Donna M. Zulman²; Susan E. Stockdale³; Alissa Simon¹; Lisa S. Meredith⁵; Gulrez Azhar⁵; Evelyn T. Chang⁴. ¹Veterans Affairs, Los Angeles, CA; ²Stanford University and VA Palo Alto, Stanford, CA; ³Greater Los Angeles VA Healthcare System, Sepulveda, CA; ⁴VA- Greater Los Angeles, Los Angeles, CA; ⁵RAND Corporation, Santa Monica, CA. (Control ID #3184137)

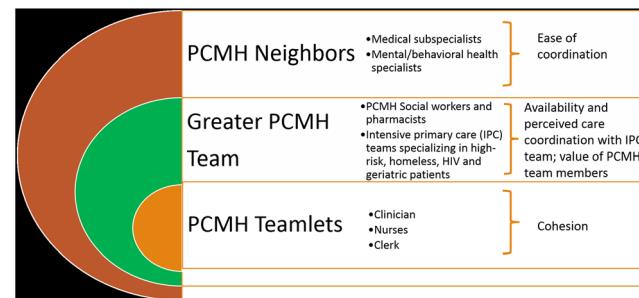

BACKGROUND: Caring for complex patients at high-risk for hospitalization may be stressful for patient-centered medical homes (PCMH) care teams. Augmenting or replacing PCMH with intensive primary care (IPC) teams may improve care for high-risk patients. IPC teams specialize in caring for vulnerable populations such as HIV, homeless, intensively managed patients, and women. Little is known about extent to which IPC teams support PCMH staff and improve satisfaction. We examine the impact of IPC teams on PCMH staff perception satisfaction with help received to care for high-risk patients and overall job satisfaction within the context of the PCMH.

METHODS: Data consisted of a cross-sectional survey of primary care providers and nurses ($N = 291$) at five Veterans Health Administration (VHA) PCMHs in 2016. Outcome measures: satisfaction with help received to care for high-risk patients and overall job satisfaction. Predictors: cohesion among core PCMH teamlet members, availability and perceived care coordination with IPC team and value of PCMH team members, and ease of coordination with PCMH neighbors (e.g., medical and mental health specialists). Covariates: staff exposure to high-risk patients, and staff characteristics (age, gender, provider type and primary care setting), and PCMH team staffing status. We performed bivariate and multiple logistic regressions, weighted for nonresponse.

RESULTS: In fully adjusted models, team cohesion among core PCMH teamlet members ($OR=1.79$; $p=0.01$), perceived care coordination with IPC team ($OR=1.29$; $p<0.01$), ease of coordination with medical subspecialists ($OR=4.05$; $p=0.01$), and spending >20 hours per week providing face-to-face care ($OR=2.64$; $p=0.01$) were significantly associated with

improved satisfaction with help received to care for high-risk patients. Staff with greater perceived workload for high-risk patients had significantly decreased satisfaction with help ($OR=0.80$; $p=0.03$). PCMH cohesion ($OR=4.64$; $p<0.01$) and perceived care coordination with IPC team ($OR = 1.15$; $p=0.03$) were also significantly associated with improved overall job satisfaction.

CONCLUSIONS: Improving PCMH team functioning may be more important than staffing levels in improving staff satisfaction. Care coordination with IPC team that is prompt, frequent, and contain helpful communication may improve PCMH staff satisfaction. Findings suggest that interventions should focus their efforts on improving PCMH teamwork and functioning.

EFFECTS OF SODIUM-GLUCOSE COTRANSPORTER-2 INHIBITORS V.S. PLACEBO AND OTHER ANTIHYPERGLYCEMIC AGENTS IN PATIENTS WITH TYPE 2 DIABETES: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS.

Jason T. Alexander¹; Erin M. Staab¹; Wen Wan¹; Melissa Franco¹; Alexandra Knitter¹; Enkhe-Tuya Montgomery¹; Celeste Thomas¹; Valerie G. Press¹; Meltem Zeytinoglu¹; Elizabeth L. Tung¹; Kathryn E. Gunter¹; Sanjay Jumani¹; Brittany Bindon¹; Shari Bolen²; Nisa Maruthur³; Elbert S. Huang¹; Louis Philipson¹; Neda Laiteerapong¹. ¹University of Chicago, Chicago, IL; ²MetroHealth/Case Western Reserve University, Cleveland, OH; ³Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3185893)

BACKGROUND: Recent evidence from large randomized trials suggests that a new class of medication, the sodium-glucose cotransporter-2 inhibitors (SGLT2Is), may reduce mortality in addition to lowering hemoglobin A1c in patients with type 2 diabetes (T2D). Even with this evidence, treatment algorithms continue to list metformin monotherapy as first-line.¹ Understanding the magnitude of benefits of SGLT2Is compared to placebo and other antihyperglycemic agents may lead to significant changes in clinical algorithms. We quantified the effects that SGLT2Is have on hemoglobin A1c and mortality by conducting a systematic review and meta-analysis of all randomized trials of this new drug class.

¹Davies MJ, D'Alessio DA, Fradkin J, et al. Management of hyperglycemia in type 2 diabetes, 2018. A consensus report by the American Diabetes Association (ADA) and the European Association for the Study of Diabetes (EASD). *Diabetologia*. 2018 Dec;61(12):2461-98.

METHODS: We searched PubMed and Scopus (inception to March 2018) for randomized trials of at least 52 weeks duration enrolling adults with T2D that compared SGLT2Is with placebo or a different antihyperglycemic agent. Two reviewers independently extracted data to ensure accuracy, and differences were resolved by third reviewer and discussion if necessary. Primary outcomes were change in hemoglobin A1c and all-cause mortality. Effect sizes and standard errors were calculated using the Hedges' g method and Mantel-Haenszel method for hemoglobin A1c and mortality, respectively. Pooled analyses with both fixed and random effect models were performed using the generic inverse variance method. Heterogeneity for each outcome was assessed with the Cochran's Q test and I^2 statistic.

RESULTS: A total of 26 randomized controlled trials comprising 43,119 patients were included in the primary analysis. Using a random effect model, patients who received a SGLT2I had a lower hemoglobin A1c when compared to placebo or other antihyperglycemic agent (mean effect size = -0.29, 95% CI -0.38 to -0.20), however heterogeneity was high (Cochran's Q = 297, $I^2 = 0.92$). Patients receiving SGLT2Is also had lower all-cause mortality (OR 0.77, 95% CI 0.67-0.90), and results were not heterogeneous (Cochran's Q = 23, $I^2 = 0$).

CONCLUSIONS: In this systematic review and meta-analysis, patients who received SGLT2Is when compared to placebo or other antihyperglycemic agent had significantly lower hemoglobin A1c levels and mortality rates. Subsequent analyses of changes in cardiovascular risk factors, adverse events, and costs will be needed to help inform future healthcare policy decisions.

EFFICACY OF A MULTI-LINGUAL MOBILE APP TO INCREASE HEPATITIS B AND C SCREENING AMONG ASIAN AMERICANS

Tung T. Nguyen¹; mandana khalili¹; Janice Y. Tsoh¹; Judith M. Walsh²; L. E. Goldman¹; Arcadi Kolchak³; Ginny gildengorin¹; Ching Wong¹; Ivy Lau¹; Vi-Van Nguyen¹. ¹University of California San Francisco, San Francisco, CA; ²UCSF, San Francisco, CA; ³San Francisco Hep B Free, San Francisco, CA. (Control ID #3185711)

BACKGROUND: There are few studies of technological interventions to address health promotion and patient-provider communication for Asian Americans, who have significant health disparities, including high rates of chronic hepatitis B but low screening rates. There are also few interventions to promote screening for hepatitis C among the appropriate risk groups in this population. **METHODS:** Using stakeholder-engaged methods, we developed an iPad app in English, Cantonese, Mandarin, and Vietnamese with: questions about personal risks and beliefs related to hepatitis B and C and their screening; tailoring audio-visual messages delivered by doctors to address patient's responses; and a printout summarizing the patient's situation and recommendations to give to primary care providers (PCPs). PCPs and their patients at two health systems were cluster randomized by provider to the intervention or comparison arm. Eligible patients were Asian Americans age 18+, spoke one of the languages, and no history of hepatitis B screening. In both arms, PCPs received a list of patients with no testing for hepatitis B every 6 months. Prior to a PCP visit, intervention participants used the app while comparison participants learned about nutrition and physical activity. Data sources included electronic health record (EHR) and surveys conducted prior to, immediately after, and 3 months after the visit. Analyses were conducted using an intent-to-treat approach and accounting for provider clusters. The dependent variables were. Generalized linear mixed-effects models (GLMM) were constructed to test the hypotheses that the intervention increased patient-provider discussion and receipt of hepatitis B or C screening in the appropriate risk groups.

RESULTS: The intervention (N=270) and comparison (N=182) participants were similar at baseline, with an overall mean age of 56.8 years (64.0% female, 79.7% foreign-born, 44.8% limited English proficient). At post-visit, intervention patients were more likely to report discussing hepatitis B (70.4% vs. 16.5%) or C (62.6% vs. 12.6%) with their providers. At 3-month, EHR data showed higher test receipt ($p<0.001$) among intervention participants for hepatitis B (37.8% vs. 7.7%) and hepatitis C (30.3% vs. 6.0%). In multivariable analyses, the intervention was very effective in increasing

test receipt of hepatitis B (OR = 7.5; 95% Confidence Interval [CI] 3.6, 15.5) and hepatitis C (OR = 10.5; 95% CI 3.0, 36.8).

CONCLUSIONS: A multi-lingual mobile app led to more viral hepatitis discussion and screening test receipt. Health information technology can improve healthcare quality among Asian Americans if designed appropriately.

EFFICACY, CLINICALLY MEANINGFUL RESPONSE, AND EARLY EFFECT OF FREMANEZUMAB IN PATIENTS WITH CHRONIC MIGRAINE

Stephen D D. Silberstein¹; David W. Dodick²; Joshua M. Cohen³; Ronghua Yang³; Melissa Grozinski-Wolff³; Xiaoping Ning³; Andrea Hinds³; Verena Ramirez Campos³. ¹Jefferson Headache Center, Philadelphia, PA; ²Mayo Clinic, Phoenix, AZ; ³Teva Pharmaceuticals, Frazer, PA. (Control ID #3185665)

BACKGROUND: Migraine is a highly prevalent and disabling neurological disorder. Chronic migraine (CM), defined as 15 or more headache days per month, at least 8 of which are migraine days, has a substantial negative impact on patients' lives. Preventive migraine treatment is recommended in patients with CM, and preventive therapeutics with an early onset of efficacy may improve the outcomes of patients with CM. Fremanezumab is a fully humanized monoclonal antibody (IgG2 a) that selectively targets calcitonin gene-related peptide (CGRP) and is approved for the preventive treatment of migraine in adults. This analysis of the HALO CM trial assessed the onset of efficacy of fremanezumab for the preventive treatment of CM.

METHODS: HALO CM was a multicenter, randomized, double-blind, placebo-controlled, parallel-group Phase 3 study evaluating the efficacy and safety of fremanezumab for the preventive treatment of CM. A diagnosis of CM was confirmed during a 28-day pre-treatment period. Adults with CM were randomized to receive either subcutaneous fremanezumab quarterly (675 mg at baseline and placebo at Weeks 4 and 8), fremanezumab monthly (675 mg at baseline, and 225 mg at Weeks 4 and 8), or matching placebo over a 12-week period. The primary endpoint the mean change in the average number of headache days of at least moderate severity: a day in which headache pain lasted 4 consecutive hours and had a peak severity of at least a moderate level, or an acute migraine-specific medication (triptans or ergots) was used to treat a headache of any severity or duration.

RESULTS: A total of 1130 patients were randomized to receive either fremanezumab quarterly (n=376), fremanezumab monthly (n=379), or placebo (n=375). Fremanezumab significantly reduced the mean number of monthly headache days of at least moderate severity during the 12-week treatment period, for both fremanezumab quarterly (least-squares mean change: -4.3 days; $P<0.0001$) and fremanezumab monthly (-4.6 days; $P<0.0001$) compared with placebo (-2.5 days). Response to treatment was seen during the first week of treatment (all-fremanezumab group [n=750]: -1.1 days; $P<0.0001$ vs placebo: -0.5 days). During the 12-week treatment period, there were reductions in the number of days with any acute headache medication use (quarterly: -3.7 days; monthly: -4.2 days; both $P<0.0001$ vs placebo: -1.9 days) and the number of migraine days (quarterly: -4.9 days; monthly: -5.0 days; both $P<0.0001$ vs placebo: -3.2 days), and a greater proportion of patients who received fremanezumab achieved at least a 50% reduction in headache days of at least moderate severity (quarterly: 38%; monthly: 41%; both $P<0.0001$), as compared with those who received placebo (18%).

CONCLUSIONS: Fremanezumab is effective for the preventive treatment of CM, with responses seen within the first week of treatment.

EFFICACY, CLINICALLY MEANINGFUL RESPONSE, AND EARLY EFFECT OF FREMANEZUMAB IN PATIENTS WITH EPISODIC MIGRAINE

David W. Dodick¹; Stephen D D. Silberstein²; Joshua M. Cohen³; Ronghua Yang³; Melissa Grozinski-Wolff³; Xiaoping Ning³; Sissy Easo-Joseph³; Carolina Burgos-Vega³. ¹Mayo Clinic, Phoenix, AZ; ²Jefferson Headache Center, Thomas Jefferson University, Philadelphia, PA; ³Teva Pharmaceuticals, Frazer, PA. (Control ID #3185671)

BACKGROUND: Migraine is a prevalent and disabling neurological disorder. The most common form of migraine is episodic migraine (EM), defined as fewer than 15 headache days per month. Patients with 3 or more headaches per month are at risk for progression to chronic migraine (CM). Preventive migraine treatment is recommended in EM patients with 4 or more headache days per month with some impairment, and preventive therapeutics with early onset of efficacy may improve patient outcomes. Fremanezumab is a fully humanized monoclonal antibody (IgG2 a) that selectively targets calcitonin gene-related peptide (CGRP) and is approved for the preventive treatment of migraine in adults. This analysis of the HALO EM trial assessed the onset of efficacy of fremanezumab for the preventive treatment of EM.

METHODS: HALO EM was a multicenter, randomized, double-blind, placebo-controlled, parallel-group Phase 3 study evaluating the efficacy and safety of fremanezumab for the preventive treatment of EM. Adults with EM, confirmed during a 28-day pre-treatment period, were randomized to receive either subcutaneous fremanezumab quarterly (675 mg at baseline and placebo at Weeks 4 and 8), fremanezumab monthly (225 mg at baseline, Weeks 4 and 8), or matching placebo over a 12-week period. The primary endpoint was the mean change from baseline in the monthly average number of migraine days: a day with 2 consecutive hours of a headache meeting criteria for migraine, probable migraine, or when acute migraine-specific medication (triptans or ergots) was used to treat a headache.

RESULTS: A total of 875 patients were randomized to receive either fremanezumab quarterly (n=291), fremanezumab monthly (n=290), or placebo (n=294). Fremanezumab significantly reduced the mean number of monthly migraine days during the 12-week treatment period, for both fremanezumab quarterly (least-squares mean change: -3.4 days; P<0.0001) and fremanezumab monthly (-3.7 days; P<0.0001) compared with placebo (-2.2 days). Response to treatment was seen during the first week of treatment (quarterly: -0.8 days; monthly: -0.9 days; both P<0.0001 vs placebo: -0.3 days). During the 12-week treatment period, there were reductions in the number of days with any acute headache medication use (quarterly: -2.9 days; monthly: -3.0 days; both P<0.0001 vs placebo: -1.6 days), and a greater proportion of patients who received fremanezumab achieved at least a 50% reduction in migraine days (quarterly: 44%; monthly: 48%; both P<0.0001), as compared with those who received placebo (28%).

CONCLUSIONS: Fremanezumab is effective for the preventive treatment of migraine, with responses seen during the first week of treatment.

ELDERLY PATIENTS' AND THEIR CAREGIVERS' PERSPECTIVES ON MEDICATION VALUE: A QUALITATIVE STUDY

Aimee N. Pickering¹; Megan E. Hamm²; Joseph T. Hanlon^{2,3}; Carolyn T. Thorpe³; Walid F. Gellad^{3,2}; Thomas R. Radomski^{2,3}. ¹University of Pittsburgh Medical Center, Pittsburgh, PA; ²University of Pittsburgh School of Medicine, Pittsburgh, PA; ³VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #3184453)

BACKGROUND: Health systems are increasingly implementing deprescribing interventions to reduce elderly patients' use of unnecessary or harmful medications. Shared decision making between prescribers and patients is an essential component of successful deprescribing, yet patients' and caregivers' perspectives on medication value and their

willingness to stop a medication are poorly understood. Our objective was to identify the most significant factors that impact the perceived value of a medication from the perspective of patients and caregivers.

METHODS: We conducted 6 focus groups (3 of patients; 3 of caregivers), each consisting of 6-8 community-dwelling adults aged 65 years, or their respective caregivers, who had been prescribed 5 medications in 2018. We sampled participants with diverse sociodemographic backgrounds and varying forms of health insurance. We explored participants' views on factors that enhance or diminish their perception of a medication's value and motivate their decision to discontinue its use. Focus groups were audio-recorded and transcribed verbatim. We developed a codebook that 2 members of the research team independently applied to each transcript, with discrepancies adjudicated by the principal investigator. We then conducted a thematic analysis to identify salient themes.

RESULTS: We identified 3 key themes. First, participants cited effectiveness as the primary factor that caused them to consider a medication to be of high value and worth taking. Patients appraised effectiveness based upon their perceived improvement in symptoms, such as pain, or objective improvement in clinical values, such as blood pressure. Caregivers considered these factors but also based their assessment upon a prescriber's recommendation without directly observing clinical improvement. Second, patients and caregivers considered a medication to be of low value and would stop taking it if it adversely affected their quality-of-life. Participants most frequently cited severity of side effects, discomfort associated with administration, or inconvenience in taking the medication. One caregiver noted, "if it's causing... debilitating pain or nausea... then I don't know if it is worth it... it's sacrificing your quality of life in your older years...." Third, while factoring less prominently, participants also cited a medication's cost as a consideration in determining its value, especially if it caused them to make other material sacrifices.

CONCLUSIONS: We identified a complex interplay of factors, including perceived effectiveness, impact on quality of life, and cost as playing central roles in patients' and caregivers' views of a medication's value and their willingness to discontinue its use. Our findings will allow health systems to incorporate a patient-centered assessment of value into systems-based deprescribing interventions and enable prescribers to more meaningfully engage older patients in shared decision making when deprescribing unnecessary or harmful medications.

ELECTIVE HIP AND KNEE REPLACEMENT: IMPACT OF SOCIAL DETERMINANTS ON POST-ACUTE CARE USE AND OUTCOMES

Shawna N. Smith¹; Ashley Snyder¹; David Ratz²; Laurence F. McMahon¹; Jennifer Meddings¹. ¹University of Michigan, Ann Arbor, MI; ²Veterans Affairs, Ann Arbor, MI. (Control ID #3182513)

BACKGROUND: The Hospital Readmissions Reduction Program (HRRP) includes elective total knee and hip arthroplasty (TKA/THA). We assessed how claims-based variables used for Medicare risk-adjustment and pre-procedure measures of social determinants of health, mobility, activities of daily living (ADL), and pain are associated with the post-acute care (PAC) type first provided after discharge and post-procedure outcomes

METHODS: Retrospective cohort study of Medicare claims was performed for index TKA/THA admissions 2010-2014 as defined by HRRP, and all PAC 90 days post-discharge for adults age 65 years with elective primary TKA/THA, merged with the closest biennial Health and Retirement Study (HRS) survey waves to measure pre-procedure social determinants of health, and pre- and post-procedure self-reported mobility limitations, ADL limitations, and pain. We examined social and clinical determinants as well as pre-post procedure changes in mobility, ADLs, and pain associated with 3 categories of PAC: home health rehabilitation (HH), outpatient rehabilitation (OutptRehab), and skilled nursing facility

or inpatient rehabilitation (SNFIptRehab). Bivariate and mixed models examined associations between social and clinical factors and first PAC discharge, and differences in pre-post-procedure change by PAC.

RESULTS: 977 TKA/THA hospitalizations (977 patients, 708 TKAs, 269 THAs) were identified with pre- and post-HRS survey data. Overall, patients post-procedure reported 0.19 fewer mobility limitations ($p=0.12$), 0.02 more ADL limitations ($p=0.77$), and fewer reported pain (55% pre-versus 44% post-procedure, $p<0.001$). 851 (87%) had Medicare PAC claims. Patients without PAC claims were younger, more likely married, had single procedure, but otherwise no different from those with PAC claims. The 276 discharged to HH were younger, more likely married, men, with children, fewer comorbidities, with single procedures compared to the 262 discharged to SNFIptRehab. Those discharged to HH were younger, more likely married, with fewer comorbidities compared to the 313 discharged to OutptRehab. PAC was not associated with pre-procedure pain, ADL or mobility limitations, wealth or race. Rates of readmission within 30 days were significantly higher for SNFIptRehab (7.6%), compared to HH (2.9%), but not significant compared to OutptRehab (5.4%). Full mixed effects models found no significant differences between HH, OutptRehab, and SNFIptRehab cohorts by pre-post changes in mobility, ADLs, or pain, though pre-post procedure pain improved significantly within each cohort; there was small but statistically significant mobility improvement for SNFIptRehab. **CONCLUSIONS:** PAC after TKA/THA differed by patient age, gender, comorbidities, and having spouse or children, but unexpectedly not by pre-procedure pain, mobility, and ADLs. Failure to address social determinants of health in policies aiming reduce PAC costs may reduce effectiveness or risk adverse outcomes.

ELIMINATING LOW-VALUE PRE-OPERATIVE CARE IN VIRGINIA: A STATE'S CALL TO ACTION

John N. Mafi^{1, 2}; Beth A. Bortz³; Kyle Russell⁴; Sitaram Vangala⁵; Chi-Hong Tseng⁶; Joshua M. Liao⁶; Bruce E. Landon⁷; Catherine Sarkisian⁸; A. M. Fendrick⁹. ¹David Geffen School of Medicine at UCLA, Los Angeles, CA; ²RAND Corporation, Santa Monica, CA; ³Virginia Center for Health Innovation, Henrico, VA; ⁴Virginia Health Information, Richmond, VA; ⁵University of California, Los Angeles, Los Angeles, CA; ⁶University of Washington, Seattle, WA; ⁷Harvard Medical School, Boston, MA; ⁸UCLA and Greater Los Angeles VA, Los Angeles, CA; ⁹University of Michigan Health Systems, Ann Arbor, MI. (Control ID #3182816)

BACKGROUND: For decades, randomized-controlled trials have repeatedly proven that routine pre-operative care for patients undergoing low-risk surgery offers little value; yet, low-value pre-operative care still occurs far too frequently. Using Virginia's All Payer Claims Database (APCD), we examine the prevalence and costs of low-value pre-operative care in order to inform a state-sponsored, randomized intervention to reduce low-value care.

METHODS: Using the 2017 Virginia APCD, we evaluated the use and costs of (1) low-value pre-operative laboratory testing, (2) low-value EKGs, chest x-rays, and pulmonary function testing (PFT), and (3) low-value cardiac imaging and cardiac stress testing among asymptomatic, low-risk patients undergoing low-risk surgery (e.g., cataract surgery). The Virginia APCD includes administrative claims data on state residents insured under traditional Medicare, Medicare Advantage, Medicaid, and commercial insurers, and it also divides the state into 5 major regions: Northern, Northwest, Central, Eastern, and Southwest. We defined low-value pre-operative care using the Milliman Health Waste Calculator, which applies Choosing Wisely® campaign recommendations and evidenced-based clinical guidelines to administrative claims data. For instance, a screening EKG in an asymptomatic, low-risk patient undergoing cataract surgery would be deemed low-value; in contrast, if the patient has chest pain or a recent myocardial infarction, then an EKG would be

considered appropriate. We estimated costs by calculating the average amount of money per service paid to a health care provider across all payers (including patients' out-of-pocket spending).

RESULTS: Among 5.4 million Virginia beneficiaries, 613,242 (11%) received 1,017,104 pre-operative services in 2017. Of these services, 487,561 (48%) were determined to be low-value, which cost the state \$227 million in unnecessary spending on pre-operative care (an estimated 0.8% of total health care spending in Virginia). Northern Virginians received the highest proportion of low-value pre-operative services: 53% of the pre-operative services were low-value (compared to 45-49% across the other four regions). Low-value pre-operative laboratory testing, low-value EKGs/chest x-rays/PFTs, and low-value cardiac imaging/cardiac stress testing comprised approximately 94%, 0.2%, and 6% of the volume and approximately 96%, 0.2%, and 4% of the spending on low-value pre-operative care respectively.

CONCLUSIONS: Low-value pre-operative care—particularly pre-operative laboratory testing—is highly common and costly in Virginia. As state governments face mounting pressure to lower health care spending, low-value pre-operative care represents an important target for local interventions to improve quality and safely lower the costs of care.

EMERGENCY DEPARTMENT VISITS AND HOSPITAL ADMISSIONS FOR OVERDOSE IN A STATE WITHOUT MEDICAID EXPANSION 2016-2017

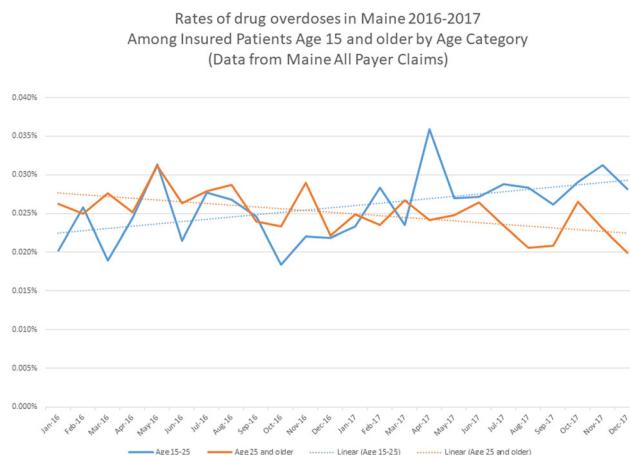

Kathleen Fairfield^{1, 1}; Kimberly Murray¹; Timothy B. Plante²; Eric Maughan¹; Susan Richardson³; Valerie S. Harder³. ¹Maine Medical Center, Portland, ME; ²University of Vermont Larner College of Medicine, Burlington, VT; ³University of Vermont, Burlington, VT. (Control ID #3185302)

BACKGROUND: Opioid use disorder increased to epidemic proportions in the past decade, and Maine has one of the worst overdose rates in the US. State legislation was passed in 2016 to reduce provider opioid prescribing through mandated checking of a Prescription Drug Monitoring Program, increased provider education, and limits on amount of opioids that could be prescribed. Simultaneously, medication assisted therapy (MAT) and illicit drug use were rising in the state. This study aims to identify the effect of these policies and changes on patterns of overdose in 2016 and 2017.

METHODS: We used Maine's all-payer claims database to identify 1,299,537 people aged 15+ with insurance eligibility between 2016 and 2017. We examined the extent and timing of emergency department (ED) visits and inpatient hospital admissions for overdose from opioids and unspecified drugs in Maine, and variations across age groups (15-24, 25-44, 45-64, 64+). We used descriptive statistics to examine differences between groups.

RESULTS: We observed a total 5,498 overdose events resulting in an ED visit or hospital admission in 2016 and 2017. These episodes decreased slightly, from 2859 (0.026%) in 2016 to 2639 (0.024%) in 2017. We observed significant differences in the rates of overdose by age category. Of the 5,498 overdose events, more events occurred in those aged 45 to 64 (38%), followed by those aged 25-44 (29%), aged 65-84 (21%), and the least in the group aged 15 to 24 (12%). Only the youngest age group (15 to 24 year olds) experienced increases in overdose from 2016 to 2017 (Figure). A higher proportion of events occurred in patients with Medicaid or dual Medicare/Medicaid coverage (54%) compared to those with Medicare only (27%) or commercial insurance (19%).

CONCLUSIONS: ED visits and hospital admissions for drug overdose decreased during 2016 to 2017 in Maine, in all age groups except the youngest. Overdoses disproportionately affected the Medicaid population. As Maine now begins Medicaid expansion and MAT programs expand, overdose may further decrease in the Medicaid population. Continued efforts to describe the groups most at risk of overdose may inform outreach, prevention, and policy efforts.

EMOTIONAL COMMUNICATION IN AMBULATORY ENCOUNTERS: HOW DOES PHYSICIAN RESPONSE TO PATIENT EMOTION IMPACT SUBSEQUENT COMMUNICATION AND VISIT LENGTH?

Mary Catherine Beach¹; Jenny Park¹; Dingfen Han¹; Hsin-Chieh Yeh¹; Somnath Saha². ¹Johns Hopkins University, Baltimore, MD; ²Portland VA Medical Center, Portland, OR. (Control ID #3186096)

BACKGROUND: It is widely cited that responding directly to patient emotions is an efficient use of time and that patients are less likely to repeat their emotional concerns if they've felt adequately understood. Because this assertion is based on limited evidence, we sought to verify it.

METHODS: We audio-recorded 41 clinicians interacting with 342 unique patients in an HIV clinic, transcribed each encounter, and used the Verona Coding Definitions of Emotional Sequences (VR-CoDES) to categorize and time-stamp patient emotional expressions and clinician responses. VR-CoDES, categorizes patient expressions as either cues (hints about emotion) or concerns (clear emotional expressions). Clinician responses are categorized as (1) providing vs. reducing space for the patient to talk further and (2) explicit vs. non-explicit in terms of addressing the emotion. Responses that reduce space are subdivided into those that provide information to the patient and those that block the patient from speaking further. We used random intercept multilevel logistic and linear regression models (accounting for clustering of emotional expressions within encounters and of patients within clinicians), evaluating whether clinician responses were associated with the time in the visit that the emotion was expressed, with subsequent patient repetition of the emotion, and with subsequent visit length.

RESULTS: The mean visit length was 30.4 minutes, with 1028 emotional expressions (750 cues and 228 concerns). Most clinician responses provided space (81%) and most were not explicit (56%). As each minute of the visit passed, clinician responses were less likely to provide space (OR 0.96 95% CI 0.95-0.98) and more likely to be explicit (OR 1.02, 95% CI 1-1.03). Emotions were more likely to be repeated (OR 2.33, 95% CI 1.66-3.27) when clinicians provided space, and less likely to be repeated (OR 0.61, 95% CI 0.47-0.80) when clinicians were explicit. When clinicians gave information in response to emotion, the patient was less likely to repeat the emotion immediately (OR 0.50, 95% CI 0.33-0.75) but more likely to repeat the emotion (OR 2.31, 95% CI 1.17-4.55) later in the visit. In adjusted analyses, visit length was shorter ($=-0.28$, 95% CI -0.54—-0.02) when clinicians provided space for patients, and longer when clinicians gave information in response to patients' emotions ($=0.42$, 95% CI 0.11—0.73). There was no association between the explicitness of clinician response and visit length.

CONCLUSIONS: These results support the widely-held belief that patients are less likely to repeat emotions when clinicians respond explicitly to them, and visit lengths are reduced when clinicians allow space for emotional discussion. Giving information to patients in response to their

emotions may result in later patient repetitions, and an increase in visit length.

EMPLOYER AND EMPLOYEE PERSPECTIVES ABOUT A VALUE-BASED BENEFIT DESIGN: DECISION-MAKING FOR OFFERING FREE MEDICINES FOR CHRONIC ILLNESS

Vanessa Simiola¹; Dennis Ross-Degnan²; Connie M. Trinacty¹. ¹Kaiser Permanente, Honolulu, HI; ²Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA. (Control ID #3186146)

BACKGROUND: Failure to take medications as prescribed has been linked to several negative health consequences for patients with diabetes. To improve health outcomes for patients with chronic illness, Kaiser Permanente, Hawaii offers a value-based insurance design (VBID) to select large employer accounts that waives all copays for essential medications and supplies for patients with chronic diseases. Since most Americans under age 65 have medical coverage through their workplace, employers play a prominent role in efforts to lower healthcare costs and increase high quality care through their coverage choices.

METHODS: Using qualitative interviews, this study seeks to understand employer perspectives and decision making for offering VBIDs within their medical insurance benefit plan. Patient surveys were conducted and linked to employer interviews to assess concordance of patient and employer perceptions. We conducted 8 interviews with representatives from five employer groups currently enrolled in a VBID program. Transcribed interviews were analyzed from a grounded theory perspective. Survey data were obtained from 287 adults with diabetes actively receiving free medicines via the VBID program.

RESULTS: Diabetes prevalence in these employers ranged from 2.2-9.8% ($M=5.5\%$). All employer groups ($N=5$) reported use of consultants to assist in determining benefits offered to employees and to complete cost-benefit analyses. Several employer representatives reported belief that VBIDs would be viewed differently amongst various facets of their insured members with the most interest amongst retirees ($n=3$) and the least interest among youngest employees (e.g., ages 18-35; $n=2$). Employers ($n=4$) also regarded the program as improving not only health behaviors within their employees but seeing effects impact families as well. Indeed, several employers provided anecdotes about how their employees demonstrated overall more confidence in their ability to manage their health and were teaching their family members how to improve health outcomes through healthy eating, health screening and overall diabetes management. These results were congruent with findings from patient surveys, where on a scale of 0-10, patients reported high confidence in their ability to maintain or improve glucose levels ($M=6.64$) in the next 6 months, and nearly 80% reported taking medications as prescribed daily.

CONCLUSIONS: Both employers offering the VBID program and employees using the VBID program reported positive outcomes in the presence of program use. Employers noted observable changes in employee behavior and employees identified confidence in their ability to manage their diabetes in the future. Results of this study demonstrate VBIDs can result in an intergenerational transmission of knowledge and behavior change within families. This study provides important information from both employer buyers and employee consumers on VBID plans that can shape the future development of VBID programs and increase uptake in commercial plans.

EMPOWERING PATIENTS TO ACT: USING GRAPHIC MEDICINE TO IMPROVE OUTPATIENT ENGAGEMENT WITH THE EHR

Tyrone A. Johnson; Jacqueline Nichols; Meera Dhadapkar; Maria L. Alkureishi; Wei Wei Lee. University of Chicago, Chicago, IL. (Control ID #3185964)

BACKGROUND: Electronic health record (EHR) use can have positive and negative effects on the patient-doctor relationship and communication.

Unfortunately, providers receive little training on EHR-related communication behaviors, and no prior studies have assessed if advocacy interventions can increase patient-EHR engagement. Given that graphic art has been effective in health education, our study aimed to evaluate the impact of graphic medicine comics in promoting patient-centered EHR use and patient engagement during outpatient office visits.

METHODS: Educational comics for patients and providers were developed using best practices from a systematic review on the effects of EHR use on doctor-patient communication, and qualitative studies on patient perceptions of the EHR. Each comic highlighted three best practices for patient-centered EHR use; patient comics advised asking to see the screen, being involved with computer use, and calling for providers' attention during periods of EHR-related distraction. Provider comics were made visible in provider workspaces for the duration of the study and highlighted three best practices: screen sharing, valuing the EHR, and utilizing patient educational resources. Patients attending appointments at the University of Chicago Primary Care Group were recruited for the study. Comics were given to patients at check-in and they were asked to complete a post-visit survey. Participants were randomly selected to complete a follow-up phone survey 1-2 months after the visit.

RESULTS: Response rate of the initial post-visit survey was 84% (198/236). 79% rated provider communication behaviors positively, 67% agreed provider communication improved compared to prior visits, and 70% agreed the comic effectively encouraged patient-EHR involvement. Decreased education level was positively correlated with increased engagement in self-advocacy behaviors, including asking to see the screen ($r_s=.273$, $p<.001$), asking to be involved ($r_s=.244$, $p=.003$), and calling for providers' attention ($r_s=.162$, $p=.049$). Female patients were more likely to ask to be involved with their doctor's computer use ($z=2.18$, $p=.030$). On phone follow-up, 90% (45/50) remembered the comic; 46% recalled at least one best-practice communication behavior. When asked about subsequent doctors' visits, patients reported increases in asking to see the screen (median 3 vs. 4, $z=2.746$, $p=0.010$).

CONCLUSIONS: This is the first study to evaluate the impact of graphic medicine on adult patients' EHR-related impressions and behaviors. Comics were effective in encouraging patient involvement, and follow-up indicates lasting impacts over time. The comic may be especially effective with female patients and populations of low-to-average educational level.

ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION OF PANCREATIC METASTASES: A RETROSPECTIVE STUDY

KEVIN LAMM: Andrew Dries; Jason Lewis; Tarun Narang. Carolinas Medical Center, Charlotte, NC. (Control ID #3184882)

BACKGROUND: Metastatic lesions to the pancreas are an uncommon but increasingly prevalent problem, accounting for 2% of pancreatic malignancies. Surgical resection is often recommended for medically fit patients with a single lesion, but in an era with rapid emergence of new chemotherapies and biologic agents, it has not been well established which modality offers the best survival. Lung, breast, renal, skin, and gastrointestinal origins are the most common metastatic primaries. It is postulated that pancreatic metastases may directly invade the ductal epithelium, causing patients to present similarly to pancreatic adenocarcinoma. We report a cohort of cases at a single medical center that utilizes endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) for diagnosis of metastatic lesions to the pancreas.

METHODS: Medical records were abstracted for patients who underwent EUS-FNA with a diagnosis of pancreatic mass. Data regarding demographics and clinical outcomes were recorded from patients with metastatic primaries.

RESULTS: There were a total number of 1,472 EUS-FNA procedures performed for evaluation of pancreatic mass from 2007-2017. Twenty-two (1.5%) of the masses were found to be from metastatic primaries. Nineteen were diagnosed with immunocytology after EUS-FNA. Small cell

carcinoma of the lung was the most common histopathology (7 of 22; 32%). In the remaining patients, the primary histopathology was lung adenocarcinoma (n=5), renal cell carcinoma (n=4), adenocarcinoma of the breast (n=1), liposarcoma (n=1), neuroendocrine tumor of the rectum (n=1), melanoma (n=1), osteosarcoma (n=1), and squamous cell carcinoma of the lung (n=1). EUS-FNA generated 7 new diagnoses of cancer including small cell carcinoma of the lung and adenocarcinoma of the lung. The most common location for metastatic lesions was the pancreatic head (8 of 22; 36%). Four masses were found in the tail of the pancreas, and all were found to be small cell carcinoma of the lung. Five of the patients have documented one year survival and one with five year survival. Surgery was performed in three patients. Hospice was pursued by nine of the patients, all with metastases from the lung.

CONCLUSIONS: Pretherapeutic diagnosis of pancreatic masses due to metastatic primaries is necessary for proper management by the multimodal treatment team. As the treatment of cancer continues to rapidly evolve, EUS-FNA with immunocytology can assist with the diagnosis of pancreatic metastases and have a major clinical role.

| Primary Cancer | Age (yrs) | # of Cases (%) | Average Size of Mass (cm) | New Cancer Diagnosis (%) | Surgery (%) | Hospice (%) | 1 year survival (%) |
|---------------------------------|-----------|----------------|---------------------------|--------------------------|-------------|-------------|---------------------|

ENGAGING PATIENTS TO PROMOTE DEPRESCRIBING OF POTENTIALLY INAPPROPRIATE MEDICATIONS

Amy Linsky^{1, 2}; Nancy R. Kressin¹; Barbara Bokhour³; Amy Rosen²; Kelly Stolzmann²; Steven R. Simon². ¹Dept of Veterans Affairs and Boston University, West Roxbury, MA; ²VA Boston Healthcare System, Boston, MA; ³ENRM Veterans Affairs Medical Center, Bedford, MA. (Control ID #3185250)

BACKGROUND: While efforts exist to prevent initiation of medications with low likelihood of benefit, fewer initiatives target medication dose reduction or discontinuation, a process known as deprescribing. While some believe providers have primary responsibility for deprescribing, patients can also facilitate deprescribing. We sought to understand how medication-specific brochures activate Veterans to discuss medications with their primary care providers and affect deprescribing of targeted medications.

METHODS: We identified Veterans at one Veterans Affairs Medical Center (VA) with primary care appointments over a 3-month period eligible for one of two cohorts: 1) chronically prescribed a proton pump inhibitor (PPI), or 2) diabetes (DM) at risk of hypoglycemia and prescribed either insulin or a sulfonylurea. Each subject was mailed a VA-tailored EMPOWER ("Eliminating Medications through Patient Ownership of End Results") brochure two weeks prior to their appointment. Patients who did not attend their appointment were excluded from analyses. Chart review identified our two outcomes: 1) documentation of discussion about the target medication (possible vs. no), and 2) target medication prescription changes (dose increase or no change vs. dose decrease or discontinuation ["deprescribing"]). Control subjects were patients seen in primary care in the month prior to the intervention who would have been eligible. Additional variables included demographics and select comorbidities and medications. Descriptive statistics examined patient characteristics and prevalence of the two outcomes. Chi-square tests examined the association of receiving brochures with discussions and deprescribing. Within each cohort, we used chi-square tests to assess relationships between patients' characteristics with each outcome.

RESULTS: There were 254 Veterans who received a brochure and attended their primary care appointment (217 in PPI, 37 in DM) and 95 Veterans in the control group (80 in PPI, 15 in DM). Subjects were predominantly male (94%), age >65 years (80%), and white (82%). There was a possible discussion for 1/95 (1.1%) control vs. 32/254 (12.6%) intervention subjects ($p=0.001$). Target medications were deprescribed for 4 (4.2%) control vs. 37 (14.6%) intervention subjects ($p=0.008$). No medication or comorbidity was statistically associated with deprescribing except within the PPI cohort,

where gastroesophageal reflux disease was statistically associated with deprescribing, with 24 (20%) of those with reflux experiencing deprescribing compared to 11 (6.25%) of those without reflux ($p=0.0004$).

CONCLUSIONS: Targeted distribution of medication-specific brochures in advance of a primary care appointment increased both discussions about and deprescribing of potentially inappropriate medications. Engaging patients can lead to changes in clinicians' prescribing practice, specifically for deprescribing. Stopping or reducing inappropriate medication has the potential to improve quality, patient safety, and efficiency.

ENGAGING USERS IN THE DESIGN OF AN MHEALTH, TEXT MESSAGE-BASED INTERVENTION TO INCREASE PHYSICAL ACTIVITY AT A SAFETY-NET HEALTHCARE SYSTEM

Patricia Avila-Garcia⁴; Sarah Nouri²; Anupama Cemballi^{1, 3}; Urmimala Sarkar^{1, 3}; Courtney Lyles^{1, 3}; Adrian Aguilera⁴. ¹UCSF, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA; ³Zuckerberg San Francisco General Hospital, San Francisco, CA; ⁴UC Berkeley, Berkeley, CA. (Control ID #3183046)

BACKGROUND: Mobile health (mHealth) interventions using text-messages are a promising approach to increasing physical activity in vulnerable populations. This participatory design study outlines the structure to address both content adaptation as well as implementation processes of a physical activity intervention delivered via text-messaging among low-income English and Spanish speakers.

METHODS: Qualitative data was collected in three stages, including one focus group and two rounds of 10 in-depth, semi-structured interviews with primary care patients at a safety-net healthcare system. Discussions focused on participant's overall experience with using text messages as part of depression treatment, influences and perceptions of physical activity, and mobile phone use. We open coded for themes within the transcripts and documented each associated change in the intervention protocol.

RESULTS: The sample was 69% female, mean age 56.2 years (range 36-72); 62% interviewed in Spanish, 65 % identified as Hispanic/Latino(a), and 46.2% reported less than a high school education. All had depression and 62% had diabetes. Specific barriers that emerged in our intervention design included low literacy and only basic use of mobile phones in everyday life, in combination with a high prevalence of co-morbid health conditions and limited mobility. These were each addressed with a specific content or implementation change in the overall intervention design (Table).

CONCLUSIONS: Conducting participatory research with end users of an mHealth intervention to increase physical activity allowed us to tailor and modify components of the text message content and format and ensure that the final intervention will engage participants most effectively.

ESTIMATING RISK OF RECURRENT GASTROINTESTINAL BLEEDS OVER PATIENTS AND TIME

Matthew A. Pappas. Cleveland Clinic Foundation, Cleveland, OH. (Control ID #3179153)

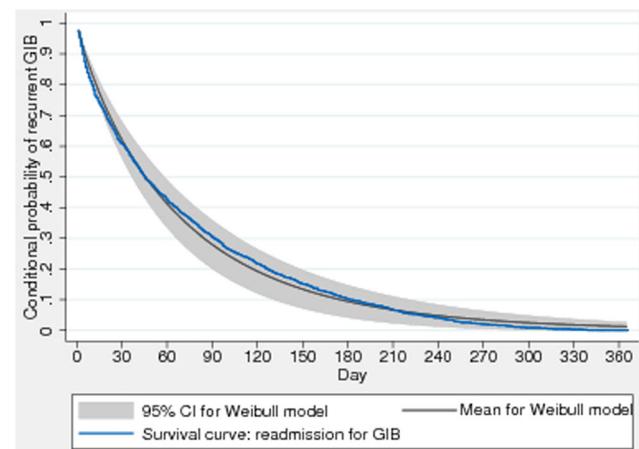

BACKGROUND: Following an anticoagulation-associated gastrointestinal hemorrhage (GIB), whether and when to resume anticoagulation is controversial. Patient-level recurrence risk is difficult to predict with accuracy, but time-based recurrence risk may be more predictable. To better inform clinical impressions and future decision-analytic models, we set out to estimate the decrease in GIB recurrence risk over time among patients with atrial fibrillation.

METHODS: Using the Nationwide Readmissions Database (NRD), a large administrative dataset of hospital readmissions, we created a two-

stage prediction model, with the first stage predicting patient-level risk of recurrence and the second stage predicting timing, conditional on recurrence. In the first stage, we used standard logistic regression and tested patient characteristics that have been previously associated with recurrent hemorrhage and that are captured in administrative datasets (e.g., cirrhosis, end-stage renal disease, number of chronic conditions). In the second stage, we compared standard survival functions (exponential, Weibull, Gompertz, lognormal, and loglogistic), selecting the survival function that best represented risk of recurrent GIB over time according to Akaike and Bayesian information criteria (AIC and BIC).

RESULTS: Our first-stage model demonstrated reasonable calibration across a 3.5-fold gradient of risk but discriminated poorly (c-statistic: 0.55). A Weibull survival function accurately explained the declining risk of recurrent GIB over time. A survival curve and Weibull model are shown in the Figure. Of patients who sustain recurrent GIB, around 50% will have done so by day 55, 80% will have done so by day 129, and 95% will have done so by day 235.

CONCLUSIONS: Using a large, nationally-representative administrative sample of patient readmission, we have estimated the risk of GIB recurrence, across patients and over time. Our patient-level discrimination was poor; datasets with physiologic parameters may be better able to predict patient-level risk. But regardless of patient characteristics, risk over time is highly predictable. Decisions to resume anticoagulation after GIB may be better tailored according to time than according to patient-level risk.

ESTIMATING THE IMPACT OF A MEDICALLY-TAILORED MEAL INTERVENTION FOR FOOD INSECURITY ON HEALTHCARE UTILIZATION: A NEAR/FAR MATCHING ANALYSIS

Seth A. Berkowitz¹; Jean Terranova²; Liisa Randall³; Kevin C. Cranston³; David B. Waters²; John Hsu⁴. ¹UNC School of Medicine, Chapel Hill, NC; ²Community Servings, Boston, MA; ³Massachusetts Department of Public Health, Boston, MA; ⁴Massachusetts General Hospital, Boston, MA. (Control ID #3152343)

BACKGROUND: Poor access to nutritious food is associated with increased healthcare use and costs, but whether interventions to improve food access can reduce this is unknown. We sought to determine whether participation in a medically-tailored meal intervention is associated with fewer subsequent hospitalizations.

METHODS: We conducted a retrospective cohort study using near/far matching instrumental variable analysis. This analytic approach combines matching on measured characteristics with instrumental variable analysis to account for unmeasured characteristics. We used linked data from the 2011-2015 Massachusetts All-Payer Claims Database (APCD), and Community Servings, a not-for-profit organization delivering medically-tailored meals (MTM). Individuals were eligible for MTM on the basis of being

chronically ill and at nutritional risk (inability to afford the foods needed to manage their condition). Among those with 360+ days of APCD data, we matched MTM recipients with non-recipients based on demographic, clinical, and neighborhood characteristics. The MTM intervention comprised weekly delivery of ready-to-consume meals tailored to individual medical needs as determined by a registered dietitian nutritionist. Distance from the MTM program was the instrumental variable. The primary outcome was inpatient admissions. Secondary outcomes were admission to a skilled nursing facility and healthcare costs (from medical and pharmaceutical claims).

RESULTS: There were 807 eligible MTM recipients. The instrumental variable passed standard tests of instruments (first stage F-statistic: 219; improved covariate balance with standardized mean difference < 0.2 for all covariates). Prior to matching, and compared with non-recipients in the same area, healthcare utilization, healthcare cost, and comorbidity were all significantly higher in recipients. For example, pre-intervention mean inpatient admissions were 1.6 (SD: 6.5) in MTM recipients versus 0.2 (SD: 0.8) in non-recipients ($p<.0001$), and mean healthcare costs were \$80,616.80 (SD: \$312,336.56) versus \$16,138.42 (SD: \$68,737.55) ($p<.0001$). Recipients were also significantly more likely to have HIV (21.9% vs. 0.7%, $p<.0001$), cancer (37.9% vs. 11.3%, $p<.0001$), and diabetes mellitus (33.7% vs. 7.0%, $p<.0001$), compared with non-recipients. In 'near/far' matching analyses, MTM receipt was associated with significantly fewer inpatient admissions, skilled nursing facility admissions, and healthcare costs (Table).

CONCLUSIONS: Participation in a medically-tailored meals program was associated with fewer hospital and skilled nursing admissions, and less overall medical spending.

EVALUATING THE CASCADE OF CARE FOR LATENT TUBERCULOSIS INFECTION AT AN URBAN PRIMARY CARE CLINIC

Amy M. Beeson^{3, 1}; Jonathan S. Schultz^{3, 1}; Joshua M. Gannon^{2, 1}; Anne Frank^{3, 1}; Kaylynn Aiona⁴; Michelle Haas^{4, 5}; Julie Venci^{3, 1}; Timothy P. Newton⁶. ¹Federico Peña Southwest Family Health Center, Denver Health, Denver, CO; ²Denver Health, Denver, CO; ³University of Colorado, Denver, CO; ⁴Denver Metro Tuberculosis Program, Denver, CO; ⁵University of Colorado School of Medicine, Aurora, CO; ⁶University of Colorado School of Medicine, Englewood, CO. (Control ID #3186203)

BACKGROUND: Screening and treatment of latent tuberculosis infection (LTBI) is a key strategy for elimination of TB in the United States. Screening and treatment based in primary care clinics may be beneficial for patients and allow for a broader reach than centralized TB clinics alone; however, the optimal strategy for scaling up testing and treatment in this setting is uncertain. From 2016-2018, providers at Denver Health's Federico Peña Clinic developed a new protocol for clinic-based LTBI treatment. We report on the current status of the LTBI treatment cascade at our clinic.

METHODS: A retrospective chart review was performed from April 11, 2016 to Dec 18, 2018 to identify patients at risk of LTBI based on birth in a high incidence country, defined as active TB incidence of >20/100,000. Among these, patients with an interferon-gamma release assay (IGRA) test result were identified. Charts of patients with positive IGRA results were then reviewed in depth to characterize the treatment cascade, including evaluation for active TB, clinical decision to treat or not, treatment initiation (defined as an initial prescription for one of three LTBI treatment regimens) and treatment completion (defined as documentation of the final monthly monitoring visit). When patients did not start treatment or discontinued treatment without documentation of clinical rationale (such as pregnancy or low risk of progression to active TB), they were considered lost to follow up.

RESULTS: There were 94,859 patient visits during the evaluation period, including 23,102 individual patients from 120 different countries. Of these, 6,566 (28%) were identified as at-risk for TB. 1,523 (23%) of these were screened for LTBI with an IGRA, of which 172 tests were positive

(11%). Among patients with positive IGRA, 153 (88.9%) were evaluated with a chest x-ray, of which 145 (94.7%) did not show evidence of active TB, while 7 were indeterminate and one identified active TB. Of those with negative x-rays, 97 (66.9%) initiated treatment, 53 (36.5%) completed treatment and 25 (17.2%) are currently on treatment. Among those with positive IGRA who did not initiate treatment (N=75, 43.6%), a clinical decision not to treat was documented in 43 cases (57.3%) while 25 (33.3%) were lost to follow-up. Of 21 women with positive IGRA during pregnancy, only one had a plan to initiate treatment, while 6 remained pregnant, precluding treatment initiation, and a majority (14) were lost to follow up post-partum.

CONCLUSIONS: While urban primary care clinics may contribute meaningfully to large-scale LTBI testing and treatment efforts, these interventions are complex. We noted significant gaps in both testing and treatment at the Peña clinic, with the largest gap in testing individuals at risk. Forthcoming improvement efforts may include standardized screening, strengthening of the clinic-wide protocol to increase treatment initiation when indicated after a positive IGRA result, and targeted efforts to improve post-partum follow-up.

EVALUATING THE EFFECT OF REPORTING PAIN ON CARE FOR ELEVATED BLOOD PRESSURE

Elizabeth Pföh; Alexander Chaitoff; Kathryn A. Martinez; Kaitlin Keenan; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #3185204)

BACKGROUND: Physicians may consider elevated systolic blood pressure (SBP) in the presence of pain to be physiologic and put off medication intensification. Our objective was to identify whether reporting pain was associated with SBP and delaying medication intensification.

METHODS: We included adult primary care patients seen in an integrated health system in 2015. Pain was identified by asking ""Are you having pain associated with your visit today?". We defined acute pain as lasting 7 days and severe pain as a rating 7/10. We defined elevated SBP as 140mmHg. Medication intensification was defined as a dosage increase or additional antihypertensive medication 1 day of the visit. We performed mixed-effect regression models adjusted for age, sex, race, marriage, insurance status and repeated visits. For patients with elevated SBP, a linear regression was used to identify the association between pain and SBP. Logistic regression was used to identify the association between pain and medication intensification after also adjusting for SBP. We used linear regressions to identify the association between pain at the 1st visit and change in SBP between the 1st and 2nd visit, after further adjustment for initial SBP and medication intensification.

RESULTS: In total, 17,357 people had 1 elevated SBP and a pain score on the same day. Patients had a mean age of 65, were majority women (60%), white (77%) and married (59%). Patients reported pain at 26% of visits, acute pain at 5% and severe pain at 12%. There was no significant difference in SBP when comparing patients who did vs. did not report pain, nor was there a difference in SBP in patients reporting acute vs. chronic pain ($p>0.05$). Patients reporting severe pain had slightly higher SBP than those reporting moderate pain ($=1.2$ mmHg; 95%CI: 0.7, 1.7). Compared to patients without pain, the adjusted odds ratio (AOR) of medication intensification with pain was 0.61 (95%CI: 0.57-0.66). The odds of medication intensification was lower for patients with acute pain vs. chronic pain (AOR: 0.53; 95%CI: 0.45-0.64), but similar for severe vs. moderate pain (AOR: 0.90; 95%CI: 0.79-1.03). Adjusted change in SBP at the 2nd visit was slightly greater for patients who initially reported pain vs patients who reported no pain ($=-1.0$ mmHg; 95%CI: -1.80, -0.19). Change in SBP was not different for patients who reported acute vs chronic pain, severe vs. moderate pain, or pain that resolved vs. persisted ($p>0.05$ for all comparisons).

CONCLUSIONS: In primary care, severe pain is minimally associated with uncontrolled hypertension, but physicians were less likely to intensify anti-hypertensive therapy in the presence of any pain. Reduction in SBP at the

following visit was only slightly greater for patients who had pain initially. Physicians should not consider pain when deciding about medication intensification for hypertension.

EVALUATION OF USE OF LONG-ACTING INSULIN IN INPATIENTS PER AMERICAN DIABETES ASSOCIATION (ADA) GUIDELINES

Richa Panara¹; Ethan Molitch-Hou¹; Erika Brechtelsbauer²; Shanza Ashraf²; Susan Henry²; Karen Robinson²; Mary Beth Clark²; Haritha Katakam²; Ingrid M. Pinzon²; Dhaval Desai²; Maria Klimenko²; Hasan Shabbir². ¹Emory University School of Medicine, Atlanta, GA; ²Emory University, Atlanta, GA. (Control ID #3185690)

BACKGROUND: The current American Diabetes Association (ADA) guidelines recommend against using correctional insulin alone for inpatient blood glucose control in patients with diabetes mellitus. The use of correctional insulin alone inadequately controls hyperglycemia, leads to larger swings in blood glucose when compared to scheduled insulin use, and increases hospital complications. Basal insulin use has been recommended for inpatient glycemic control for more than a decade. We analyzed the frequency of prescribing guideline-recommended basal insulin for hospitalized patients with a blood glucose greater than 180mg/dL within our healthcare system.

METHODS: All hospital encounters at four hospitals within a quaternary healthcare system involving patients above the age of 18 admitted to the medical and surgical wards from September 1, 2017 to September 30, 2018 with an inpatient blood glucose greater than 180 mg/dL were reviewed. Information was obtained from a clinical data warehouse. Patients in critical care units, pregnant patients and patients with an admission diagnosis directly influencing insulin use such as hyperglycemia, hypoglycemia, ketoacidosis, and hyperosmolar states were excluded from the analysis.

RESULTS: A total of 11,752 patient encounters were analyzed. Of these encounters, 42% were started on basal insulin during the hospitalization (2% Basal alone, 3% Basal/Bolus, 44% Basal/Bolus/Correctional, 51% Basal/Correctional.) 39% were treated with lone correctional insulin, and 17% were not started on insulin of any kind. Basal insulin was used more commonly if admitted by a Medicine service compared to Surgical service (45% vs. 25% p < 0.01), the patient was on home basal insulin (90% vs. 60% p < 0.01), the patient had an A1c > 9% (85% vs. 43% p < 0.01), or an order set was used (70% vs. 30% p < 0.01). The use of basal insulin resulted in more patient days with hypoglycemia (<70mg/dL, 0.64d vs. 0.29d, p<0.01) and hyperglycemia (>299mg/dL, 2.3d vs. 0.5d, p < 0.01).

CONCLUSIONS: This study showed that ADA guidelines for inpatient insulin dosing are being underutilized in multiple hospitals within a quaternary healthcare system. Only 42% of patients were prescribed basal insulin during hospitalization. While hyperglycemia and hypoglycemia were worse in the basal insulin group, this group was more likely to have worse glucose control prior to admission. Implementing a guideline-derived inpatient order set could increase prescribing of a basal-bolus insulin regimen.

EVIDENCE REVIEW: MODIFIABLE RISK FACTORS AND INTERVENTIONS TO PREVENT OR DELAY LONG-TERM NURSING HOME PLACEMENT FOR ADULTS WITH IMPAIRMENTS

Wei Duan-Porter^{3, 2}; Kristen Ullman³; Christina Rosebush³; Lauren McKenzie³; Nancy Greer³; Kristine E. Ensrud^{3, 4}; Edward Ratner^{1, 2}; Tetyana Shippee⁴; Joseph Gaugler⁴; Timothy Wilt^{3, 2}. ¹Minneapolis VA Health Care System, Minneapolis, MN; ²University of Minnesota Medical School, Minneapolis, MN; ³Minneapolis VA, Minneapolis, MN; ⁴University of Minnesota, Minneapolis, MN. (Control ID #3185374)

BACKGROUND: To help adults with physical or cognitive impairments remain in community settings, national efforts have sought to improve access to home and community-based services (HCBS) and rebalance funding. In

this review of reviews, we examined modifiable risk factors for long-term nursing home placement (NHP) and intervention effects on preventing or delaying NHP.

METHODS: Multiple databases were searched, and additional references sought from experts. Eligible systematic reviews (SR) examined frailty, other risk factors, and various interventions. Abstracted data included: study characteristics; target population; NHP ascertainment; and risk factor or intervention category. Using predetermined criteria, we prioritized a subset of SR for further abstraction of detailed results: meta-analysis or qualitative synthesis of effects, moderation effects, datasets used, NHP ascertainment, quality of included studies, and overlap in studies.

RESULTS: Of 7014 unique citations, we found eligible 67 SRs (20 on risk factors, 47 for interventions); all included older adults with impairments, or at risk for impairments due to age or medical burden. Eighteen SR were high quality, 10 were umbrella reviews, and 46 included randomized controlled trials. Few SR discussed how studies assessed NHP; those that examined this question found that most studies used participant (or family) reports or had unclear NHP ascertainment. Main results from the subset of eligible SR (6 for risk factors, 20 for interventions) are summarized in Table.

CONCLUSIONS: Comprehensive case management and caregiver support showed some benefit, although results were inconsistent. Future studies should compare effects of interventions that target similar factors in alternative settings (eg, home vs. clinic), and consider follow-up periods >2 years.

EVOLUTION OF NURSING ROLES AND NURSE-PHYSICIAN COLLABORATION DURING IMPLEMENTATION OF VA'S PATIENT-CENTERED MEDICAL HOME: KEY STAKEHOLDER PERSPECTIVES

Alicia Bergman¹; Danielle Rose²; Linda Kim³; Alison B. Hamilton⁴; Susan E. Stockdale⁵. ¹VA Greater Los Angeles, North Hills, CA; ²VA GLA Healthcare System, Sepulveda, CA; ³VA-Greater Los Angeles, Los Angeles, CA; ⁴VA Greater Los Angeles Healthcare System, Los Angeles, CA; ⁵Greater Los Angeles VA Healthcare System, Sepulveda, CA. (Control ID #3184426)

BACKGROUND: Effective nurse-physician collaboration is essential for providing quality health care, but long-standing relationship challenges have been reported between these professions. Recent studies have explored the impacts of the patient-centered medical home (PCMH) model on primary care providers and teams, but a targeted investigation into nurses' and physicians' respective roles and interprofessional dynamics with one another is missing. Veterans Health Administration (VHA) implemented PCMH in 2010. The goal of this study was to explore primary care provider (PCP) and nurse (RN) interprofessional collaboration against the backdrop of evolving RN roles during PCMH implementation.

METHODS: Qualitative interviews were conducted with 47 key stakeholders (e.g., primary care and nursing leaders) as part of a PCMH implementation evaluation in 3 VA healthcare systems. Interviews were recorded, transcribed, and analyzed to identify major themes regarding RN roles and RN-PCP interprofessional collaboration.

RESULTS: Key stakeholders perceived that: 1) PCPs and RNs understood PCMH RN roles differently; 2) PCPs expected RNs to work above the top of their license; 3) RNs were not working at the top of their license; and 4) PCPs were coping with deviations from a traditional physician/RN model. Differences in understanding of the RN roles were perceived to derive from separate reporting structures between PCPs and RNs, and nursing roles being translated and practiced differently across different PCMH teams. With regard to perceived PCP expectations, key stakeholders noted that some nurses took on extra work (beyond their scope) in order to appease PCPs. Other key stakeholders described how RNs were not working at the top of their license for reasons including PCP territoriality, inadvertent creation of clerical work hindering dedication of sufficient time to higher functioning tasks,

and/or a lack of prior exposure to and/or experience with higher-level tasks (e.g., chronic disease management). Key stakeholders also recounted observing physician resistance to the less hierarchical and more team-oriented model of the RN-PCP relationship promoted in PCMH, and they recalled instances of power struggles as physicians resisted evolving RN autonomy and/or new reporting structures.

CONCLUSIONS: Key stakeholders had diverging perspectives on the nature of RN tasks being performed, but most agreed that there was confusion in PCMH over RN roles; many perceived that a breakdown of the traditional PCP/RN hierarchical structure was being met with resistance by some physicians. A key aim of PCMH models is to use team-based approaches to improve patient care, but challenges to RN-PCP collaboration can make implementation of such models more difficult. These findings highlight areas for improvement and can guide the development of future trainings.

EXAMINATION OF INTERNAL MEDICINE, PEDIATRIC AND FAMILY MEDICINE RESIDENTS' PERCEPTIONS, SKILLS, AND PRACTICES IN DELIVERING CROSS-CULTURAL CLINICAL CARE

Eun Ji Kim¹; Lyndonna M. Marrast¹; Omolara T. Uwemedimo³; Shari Jardine²; Johanna Martinez¹. ¹Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; ²Northwell Health, New Hyde Park, NY; ³Zucker School of Medicine at Hofstra/Northwell, New Hyde Park, NY. (Control ID #3185108)

BACKGROUND: Social determinants of health (SDH) encompass conditions arising from where people are born, live, learn, and work. SDH affect more than half of patient health outcomes and the presence of health harming needs have been associated with poor health outcomes. The purpose of this study is to assess previous education in SDH-related topics and examine the translation of resident education into preparedness, skillfulness, and clinical practice to address patients' SDH.

METHODS: In the beginning of the academic year, Internal Medicine, Pediatrics, and Family Medicine residents were asked to complete a survey containing questions about sociodemographic background, cross-cultural characteristics, and prior education or training in SDH. The survey also contained questions about self-perceived preparedness, skillfulness, and clinical experience addressing SDH. We conducted descriptive analysis of resident's responses to the survey and examined characteristics associated with skillfulness.

RESULTS: The study included 160 residents from Internal Medicine (n=87), Pediatrics (n=63), and Family Medicine (n=10). The study sample respondents self-identified as 36.9% White, 6.9% Black, 8.1% Hispanic, 36.9% Asian, and 11.2% Other. About a quarter (27.5%) of residents reported coming from a disadvantaged background (low income, limited English proficient, or attending a school with high dropout rate). A majority of the residents spoke another language other than English (58.8%) and had a parent who was born outside of the US (65.0%). Residents reported prior education or training in health disparities (75.6%), SDH (83.8%), and community health (57.5%). Despite the majority of the residents reporting prior education in various cross-cultural topics (reported range 63.1-98.1%), there were wide variations in perceived preparedness in addressing patients with cross-cultural differences (24.4% prepared to care for patients with a distrust of healthcare system and 51.3% prepared to care for patients with limited English proficiency or from a different culture). Very small percentages of residents regularly asked patients about social needs, including homelessness (4.1%), affordable housing (2.7%), food insecurity (0.0%), and unhealthy living conditions (9.5%). Residents perceived level of

skill in providing cross-culture care increased when they had received medical school education in social history, including identifying 1) how well a patient can read or write English, 2) religious beliefs that might affect clinical care, 3) cultural customs that might affect clinical care, and 4) how a patient makes decisions with other family members.

CONCLUSIONS: Medical school teaching in cross-cultural care is associated with improved self-perception of skill in addressing patients SDH among residents. Graduate medical education that is inclusive of cultural competency, social justice, and health equity may improve trainees' perceptions, readiness, and skill for clinical practice adept in addressing SDH.

EXAMINATION OF THE ASSOCIATION BETWEEN LIFE-COURSE SOCIOECONOMIC STATUS, ACCULTURATION, AND HYPERTENSION AMONG UNITED STATES IMMIGRANTS WITH AND WITHOUT DIABETES

Aprill Z. Dawson; Rebekah J. Walker; Leonard E. Egede. Medical College of Wisconsin, Milwaukee, WI. (Control ID #3185017)

BACKGROUND: More than 42 million immigrants live in the United States (US), and are more likely to work low paying jobs, live in poverty, and lack health insurance. It is known that ethnic minorities are disproportionately affected by hypertension and diabetes. Immigrants face additional challenges in disease management due to barriers to accessing care, limited English proficiency, and cultural differences. Therefore, the aim of this study was to understand the relationship between life-course socioeconomic status (SES), acculturation, and hypertension among US immigrants with and without diabetes.

METHODS: Data from the New Immigrant Survey, a multi-cohort study of documented US immigrants, was analyzed. Logistic regression with hypertension as the outcome was used to investigate the relationship between acculturation & life-course SES in adult US immigrants with and without diabetes. The acculturation variable included measures of English proficiency (understand, speak, read, write) and length of residence in the US (>15 years). Life-course SES included father's education, mother's education, number of siblings, individual's level of education, income, and employment status. Hypertension and diabetes were measured by self-report.

RESULTS: 8533 US immigrants, 317 of which had diabetes were included in the study. 659 immigrants without diabetes had hypertension, and 121 with diabetes had hypertension. Unadjusted models found a significant association between life-course SES and hypertension in those without diabetes (OR:0.83; p<0.001) and with diabetes (OR:0.58; p<0.001). After adjustment for age, sex, race/ethnicity, and marital status significance only remained among immigrants with diabetes (OR:0.68; p=0.033). Acculturation was significantly associated with hypertension among immigrants without diabetes in the unadjusted model (OR:1.35; p=0.001), however significance did not hold after adjusting for demographics.

CONCLUSIONS: US immigrants with diabetes and with higher life-course SES were found to have reduced risk of having hypertension whereas this relationship was not seen in immigrants without diabetes. Additionally, acculturation was not identified as a significant predictor of hypertension among US immigrants with or without diabetes. Similar to US-born adults, our findings support the idea of socio-economic status across the life-course being associated with the development of chronic disease in US adults. Additionally, these results suggest that low SES immigrant populations with diabetes may be at high risk for hypertension and should be the focus of culturally tailored interventions.

EXAMINING FACTORS ASSOCIATED WITH NICOTINE REPLACEMENT THERAPY USE AMONG ASIAN AMERICAN MALE SMOKERS

Fiona Ng^{1, 4}; Hallen Pham^{1, 4}; Janet Chu^{2, 4}; Ginny gildengorin^{1, 4}; Susan Stewart^{5, 4}; Alice Guan^{1, 4}; Edgar Yu^{3, 4}; Angela Sun^{6, 4}; Joyce Cheng^{6, 4}; Tung T. Nguyen^{2, 4}; Janice Y. Tsoh^{3, 4}. ¹University of California, San Francisco, San Francisco, CA; ²UCSF, Livermore, CA; ³University of California San Francisco, San Francisco, CA; ⁴Asian American Research Center on Health, UCSF, San Francisco, CA; ⁵University of California, Davis, Davis, CA; ⁶Chinese Community Health Resource Center (CCHRC), San Francisco, CA. (Control ID #3161742)

BACKGROUND: Compared to the average prevalence of smoking in California (16%), smoking prevalence remains disproportionately high among Vietnamese (30%) and Chinese (27%) men with limited English proficiency. Asian Americans are less likely to use and to receive nicotine replacement therapy (NRT) prescriptions, an evidence-based smoking cessation intervention. Additional barriers to NRT-use in this population include misconceptions of its side effects, skepticism of its effectiveness compared to willpower alone, and preference for non-pharmacological strategies. This study examined factors associated with NRT-use among Asian American male daily smokers.

METHODS: Participants consisted of dyads formed by a Chinese or Vietnamese daily smoker and a non-smoking family member. In this randomized controlled trial, dyads received a family-centered education intervention taught by lay health workers (LHW) on either smoking cessation (n=166) or nutrition and physical activity (n=159). Bivariate and multivariable regression analyses were used to identify factors associated with NRT-use reported at 3-months after enrollment. Treatment group, demographics, and the following baseline Information-Motivation-Behavioral Skills Model (IMB) constructs were examined: information (harms of tobacco use, effectiveness of NRT), motivation (family support, discussion with doctor, intention to quit), and behavioral skills (24-hour quit attempt, self-efficacy).

RESULTS: The sample consisted of 163 Vietnamese and 162 Chinese men who smoked daily at the time of enrollment (mean age=54.7). All but one participant were foreign born; 98% spoke limited English; 74% had high school or less education. On average, the participants have smoked for 28.3 years with a mean of 9.4 cigarettes smoked daily; 46% had no intent to quit in 6 months; and 49% smoked 30 minutes after waking (indicating high nicotine dependence). At 3 months post-enrollment, smoking cessation group yield higher NRT-use than the control group (12% versus 6.9%) [(AOR=3.28, p=.01)]. In multivariable analysis, independent of group assignment the following IMB constructs were associated with NRT-use: motivation (frequent encouragement from family member to use cessation resources [AOR=2.04, p<.01], discussion with doctor about smoking [AOR=5.24, p<.01], intention to quit 6 months [AOR=2.57, p=.049]) and behavioral skills (at least one 24-hour quit attempt in the year prior to study [AOR=3.69, p=.01]).

CONCLUSIONS: While LHW-led family-based smoking cessation intervention increased NRT-use among Chinese and Vietnamese male smokers, utilization remains low. Information on the harms of tobacco and efficacy of cessation resources alone were insufficient. Our findings underscore the importance of healthcare providers promoting NRT-use with an understanding of personal and cultural barriers. Efforts to improve NRT-use among this population should also involve empowering family members to discuss cessation resources with smokers.

EXAMINING THE ASSOCIATION OF SOCIAL DETERMINANTS OF HEALTH WITH 30-DAY READMISSION AND MORTALITY IN OLDER VETERANS WITH CONGESTIVE HEART FAILURE

Charlie M. Wray^{1, 2}; Marzieh Vali³; Louise Walter¹; Wendy Chapman⁴; Brett South⁴; Amy L. Byers^{1, 2}; Salomeh Keyhani⁵. ¹University of

California, San Francisco, San Francisco, CA; ²San Francisco VA Medical Center, San Francisco, CA; ³NCIRE, San Francisco, CA; ⁴University of Utah, SLC, UT; ⁵University of California at San Francisco, San Francisco, CA. (Control ID #3185361)

BACKGROUND: The Veterans Health Affairs (VA) closely tracks 30-day readmission and mortality rates among patients hospitalized for congestive heart failure (CHF). While previous work has identified multiple factors that are predictive of readmission and death, social determinants of health (SDOH) are often not examined due to the difficulty in extracting this information from clinical databases. We previously extracted four SDOH (see Table) that are commonly associated with poor clinical outcomes. We examined whether SDOH were associated with 30-day readmission and mortality in the VA's integrated health care system.

METHODS: We randomly selected 1500 elderly (65 years and older) Veterans hospitalized in the VA with a primary admission diagnosis of CHF in 2012. We identified 25 candidate variables associated with the outcomes of interest in CMS hospital profiling models. SDOH were independently extracted by two reviewers from patient charts. We examined the association of each clinical variable with the outcome of interest (30-day readmission or 30-day mortality) and retained variables significant in univariate analysis ($p<0.1$) in subsequent analyses. Using multivariate logistics regression, we examined the association between the four SDOH and 30-day hospital readmission and 30-day mortality after adjusting for age and clinical factors.

RESULTS: Of the 1500 patients, 312 (21%) were readmitted while 85 (6%) died within 30 days of discharge. In multivariate analysis, lack of social support (OR 5.37; 95% CI 1.53-19.81), higher AlaRMS Score (OR 1.01; 95%CI 1.00-1.02), or renal failure (OR 1.39; 95%CI 1.05-1.83) were associated with higher 30-day readmissions. Of note, marginal housing (or receipt of housing services) appeared to decrease a patients' propensity to be readmitted to the hospital (OR 0.24; 95% CI 0.03-0.91).

CONCLUSIONS: Of the four SDOH we examined, only 'lack of social support' was shown to be associated with higher 30-day readmission, and none were associated with 30-day mortality. Patients with marginal housing (or who were received housing services) were less likely to be readmitted. The VA's extensive outpatient and social safety net programs may be attenuating the deleterious effects SDOH commonly have on health outcomes in other settings. Future work should focus on how these SDOH effect other, younger patient populations within the VA, and what social services may be mitigating risk.

Patient Characteristics & Social Determinants of Health Associated with Outcomes

| | Clinical & Patient Characteristics | | | | |
|---|------------------------------------|---|-------------------------|---|-------------------------|
| | Mean | 30-day Readmission Unadjusted OR (95% CI) | Adjusted OR (95% CI) | 30-day Mortality Unadjusted OR (95% CI) | Adjusted OR (95% CI) |
| Age | 77.9 | 1 (0.99-1.02) | 0.99 (0.97-1.01) | 1.03 (1-1.05) | 0.99 (0.97-1.03) |

Note: Only clinical variables that were significantly associated with outcome were included in the table. Multivariate analyses also controlled for age and the following comorbid conditions: PCI, CABG, CAD, valvular heart disease, arrhythmias, stroke, renal failure, COPD, pneumonia, diabetes, dementia, functional disability, metastatic cancer, major psychiatric disorder, chronic liver disease, severe hematologic disorder, iron deficiency, depression, ESRD, decubitus skin ulcers. OR: Odds Ratio; AlaRMS: Acute Laboratory Risk of Mortality Score. * $P<0.05$, NS: Not significant in univariate analysis

EXAMINING THE AWARENESS OF UNHEALTHY WEIGHT AMONG CHINESE AMERICAN AND VIETNAMESE AMERICAN IMMIGRANTS

Hallen Pham¹; Fiona Ng¹; Janet Chu¹; Ginny gildengorin¹; Susan Stewart²; Edgar Yu¹; Alice Guan¹; Angela Sun³; Joyce Cheng³; Tung T. Nguyen¹; Janice Y. Tsoh¹. ¹University of California, San Francisco, San Francisco, CA; ²University of California, Davis, Sacramento, CA; ³Chinese Community Health Resource Center (CCHRC), San Francisco, CA. (Control ID #3147717)

BACKGROUND: The World Health Organization (WHO) recommends lowering the cutoff for overweight body mass index (BMI) for Asians from 25 to 23 due to disproportionately higher risks of having diabetes among Asians with BMI 23. Self-awareness of being overweight or obese correlates positively with healthy weight management. This study aims to examine the factors associated with lack of awareness of unhealthy weight among Chinese American and Vietnamese American immigrants.

METHODS: This study analyzed pre-intervention survey data from 680 participants enrolled in a randomized trial to promote smoking cessation and healthy eating. Participants were male daily smokers accompanied by a non-smoking family member to form a smoker-family dyad. All participants were asked "Do you think your current weight is at a healthy range?" BMI was computed from self-reported height and weight. Participants whose BMI 23 but self-perceived their weight to be in a healthy range were considered as unaware of their unhealthy weight. For the subset of participants with BMI 23, bivariate and multivariable logistic regression models using generalized estimating equation to account for within-dyad clusters were conducted to identify correlates of being unaware of one's unhealthy weight.

RESULTS: Participants included 346 Chinese Americans and 334 Vietnamese Americans: 53.5% male, 99.3% foreign born, 95.8% limited English proficiency, and 41.9% had less than a high school education. About half of participants had BMI 23 (50.2%, n=319). Among those with BMI 23, 46.7% had BMI between 23 and 24.9, which would have been categorized as healthy weight by the standard BMI cutoff of 25. Of those with BMI 23, 58.9% were unaware of their unhealthy weight, and only 22.3% reported discussing weight with their doctor within the last year. Among those who discussed weight with their doctor, 36.6% remained unaware of being overweight or obese. In multivariable analysis, factors associated with lack of awareness of being overweight or obese included being male (OR=2.96, 95% CI: 1.58-5.53), perceiving good/excellent general health (OR= 2.95, 95% CI: 1.66-5.23), having BMI between 23 and 25 (OR=4.37, 95% CI: 2.62-7.27), and not discussing weight with their doctor (OR= 3.13, 95% CI: 1.69-5.82).

CONCLUSIONS: A majority of Chinese American and Vietnamese American immigrants with BMI 23 lacked awareness about being overweight. Those who did not discuss weight with their doctors were at increased odds of overweight unawareness, but some remained unaware even after discussion with their doctor. These findings underscore the need for targeted interventions to help patients understand healthy weight range and weight management to prevent and improve health outcomes for diseases associated with being overweight or obese. Interventions should also engage healthcare professionals to increase weight discussions with their Asian patients utilizing recommended BMI cutoff of 23.

EXAMINING THE REPLETION REFLEX: THE ASSOCIATION BETWEEN SERUM POTASSIUM AND OUTCOMES IN HOSPITALIZED PATIENTS WITH HF

Kevin F. O'Sullivan^{3, 2}; Mohammad A. Kashef^{4, 3}; Alexander B. Knee^{3, 3}; Alexander S. Roseman³; Penelope S. Pekow³; Mihaela S. Stefan^{3, 3}; Meng-Shiou Shieh³; Quinn R. Pack^{3, 4}; Peter K. Lindenauer^{3, 3}; Tara Lagu^{3, 3}. ¹Hamden and Franklin Cardiovascular Associates, Springfield, MA; ²University of Massachusetts Medical School, Worcester, MA; ³University of Massachusetts Medical School-Baystate Medical Center, Springfield, MA; ⁴Baystate Medical Center, Springfield, MA. (Control ID #3184657)

BACKGROUND: Many physicians monitor their hospitalized patients' potassium levels daily and replete as needed to maintain serum potassium 4.0 mEq/L. The evidence basis for this practice is relatively weak. We aimed to evaluate the association between serum potassium levels and outcomes in patients admitted with heart failure (HF).

METHODS: We identified patients with acute HF exacerbations admitted to hospitals that contributed to an electronic health record (EHR)-

derived dataset in the years 2010-2012. In a subset of patients with normal serum potassium (3.5-5.0 mEq/L) at the time of admission, we averaged serum potassium values within a 72-hour exposure window during and just after admission. We categorized average serum potassium during this window as less than 4.0 mEq/L (low normal), 4.0-4.5 mEq/L (medium normal), or greater than 4.5 mEq/L (high normal). We created multivariable models examining the association between these categories and outcomes (inpatient mortality, length of stay, and admission to ICU after the "exposure window"), adjusting for patient demographics, comorbid conditions, and presenting severity (using the Laboratory-based Acute Physiology Score (LAPS-2), which includes admission blood urea nitrogen and creatinine levels as well as anion gap).

RESULTS: We included 4,995 patients, of which 2,080 (41.6%), 2,326 (46.6%), and 589 (11.8%) were in the low, medium, and high cohorts, respectively. The <4.0 mEq/L and 4.0-4.5 mEq/L groups were relatively similar in terms of age, sex, illness severity (LAPS-2), and comorbidity score. Compared to these groups, the group with mean potassium >4.5 mEq/L group had higher admission creatinine, more chronic kidney disease, more deficiency anemias, and more chronic obstructive pulmonary disorder. Overall, 3.7% (n=187) of patients died during the hospitalization, 2.4% (n=98) were admitted to ICU after the exposure window and median length of stay was 5.6 days. After adjustment, we observed a trend towards higher risk of mortality (OR = 1.51; 95% CI = 0.97 to 2.36) and ICU transfer (OR = 1.78; 95% CI = 0.98 to 3.26) and a statistically significant longer length of stay (median of 0.57 days; 95% CI = 0.21 to 0.93) in patients with a potassium level of >4.5 mEq/L.

CONCLUSIONS: In this large observational study of patients hospitalized with an acute HF exacerbation, we found no association between low normal serum potassium and negative outcomes. Compared to those with mean potassium values <4.0 mEq/L, potassium values of >4.5 mEq/L were associated with worse outcomes, but this was attenuated after adjustment. This suggested that factors beyond potassium values influenced the observed relationship. Because daily potassium repletion represents a huge cost in time, money, and effort, to physicians, nurses, hospitals, laboratories, and healthcare payers, future pragmatic trials could attempt to disentangle the associated risks and benefits of potassium repletion and identify the best treatment methods going forward.

EXECUTIVE PHYSICALS IN THE VALUE ERA: ARE TOP MEDICAL CENTERS LEADING THE WAY?

Deborah R. Korenstein; Maha Mamoor; Peter Bach. Memorial Sloan Kettering Cancer Center, New York, NY. (Control ID #3182494)

BACKGROUND: Executive physical programs are one to two-day comprehensive evaluations offering "preventive" testing/screening. Program fees cover all included testing; subsequent services in response to findings are billed to insurers. Amidst widespread efforts to improve healthcare value, executive physicals have been criticized as wasteful and non-evidence-based, but no studies have described their offerings. As top-ranked academic hospitals may be viewed as role-models in appropriate care, we set out to describe the prevalence of executive physical programs in top US academic hospitals and to characterize included non-laboratory testing.

METHODS: We searched websites of the 20 hospitals included in the US News & World Report 2018-2019 hospital "honor roll" for information about executive physical programs and recorded prices and services offered. When information was incomplete, we performed Google searches and telephoned representatives to inquire about programs. When hospitals provided different packaged services based on age or price, we recorded information for each package separately. We divided services into 7 domains: cardiovascular risk review, cardiac screening, ENT/Ophthalmology, cancer screening, lung disease screening, bone health, and total body CT. We assessed the appropriateness of each service based on US Preventive Services Task Force (USPSTF) guidelines as:

recommended, non-recommended (NR), risk- or age-based (RB), and insufficient evidence (IE). For these determinations we assumed all patients were under age 65. The study was deemed exempt by the MSKCC IRB.

RESULTS: Seventeen (85%) hospitals offered executive physicals. We identified services included in 20 packages across 13 hospitals; information was unavailable for 4 hospitals. Package price ranged from \$1700-\$9400. The most commonly offered services were screening ECG (included in 90% of packages), hearing exam (75%), and stress testing (70%); all are NR. Across packages, cancer screening was the most common domain, with 48 cumulative services (12 [25%] NR), followed by cardiac screening (n=32, all NR), ENT/ophthalmology (n=25, all IE), and lung disease screening (n=19, all NR). Overall, among unique services offered in any package (n=16), 1 (6.3%) was recommended by USPSTF, 6 (37.5%) were NR, 5 (31.3%) were RB, 3 (18.8%) were IE, and 1 was not addressed by USPSTF. Notably, few hospitals included pap/pelvic exam (54%), which is recommended by USPSTF, or abdominal ultrasound for AAA screening (23%) (deemed RB per USPSTF), none offered lung cancer screening (RB), and 1 offered total body CT.

CONCLUSIONS: Most top academic hospitals offer executive physical programs; public information on these programs is incomplete. Price varies, non-recommended services are common, and some recommended services are omitted. With growing emphasis on value, leading hospitals should align executive physical offerings with best evidence.

EXPANDING SUPPLY OF MEDICATION ASSISTED TREATMENT TO UNDERSERVED AREAS: BUPRENORPHINE WAIVERS FOR ADVANCED PRACTICE PROVIDERS

Michael L. Barnett¹; Dennis Lee¹; Richard Frank². ¹Harvard T.H. Chan School of Public Health, Boston, MA; ²Harvard Medical School, Boston, MA. (Control ID #3181480)

BACKGROUND: There are large segments of the country where access to evidence-based treatment for opioid use disorder (OUD) is limited by the lack of clinician supply. To help address the limits of OUD treatment capacity, the Comprehensive Addiction and Recovery Act (CARA) passed in July 2016 enabled nurse practitioners and physicians' assistants (NP/PA) to obtain federal waivers to prescribe buprenorphine, an effective medication for treating OUD, after 24 hours of training. We examined the take-up and use of these waivers by NPs and PAs and their association with scope of practice laws.

METHODS: We obtained the date and county of buprenorphine waiver approval for all clinicians including NP/PAs from 2005-2017 from the Substance Abuse and Mental Health Services Administration, merged with publicly available county demographic characteristics and 2016 opioid mortality data. We captured buprenorphine prescribing from the publicly available Drug Enforcement Agency databases. Using linear regression, we estimated the associations in characteristics of counties with the highest vs. lowest quartiles of waivered NP/PAs per capita by the end of 2017. Next, we estimated a county- or 3-digit ZIP- quarter level linear regression with geographic fixed effects to quantify changes post-CARA in buprenorphine prescribing per capita. We compared growth in these outcomes between states with fully independent vs. restricted scope of practice laws for NP/PAs as of 2016.

RESULTS: By the end of 2017, 3,682 NPs and PAs in 812 counties representing 75% of the US population obtained buprenorphine waivers, including 39 counties with no buprenorphine-waived providers before 2017. Among counties with any waivered NP/PAs, there were 6.2 vs. 0.6 waivered NP/PAs per 100,000 in counties in the top vs. bottom quartiles of NP/PA waiver adoption. Top quartile counties had significantly higher opioid-related mortality per 100,000 in 2016 than bottom quartile counties (18.4 vs. 13.2, adjusted p<0.001). By the end of 2017, counties in states with full vs. restricted scope of practice had over twice as many waivered NP/PAs per 100,000 (2.2 vs. 0.9, p<0.001). Annual buprenorphine

prescribing per capita grew faster in 2017 after CARA passage than from 2005-2016 (15.2% faster annual growth vs. national average, p<0.001), but there was no difference in growth between states with full vs. restricted scope of practice regulations (p=0.27).

CONCLUSIONS: One year after CARA passage, thousands of NP/PAs obtained buprenorphine waivers despite the 24-hour training requirement, many of whom were in counties with no prior buprenorphine providers. There was greater adoption in states where NP/PAs could practice independently, though buprenorphine prescribing did not grow faster in states with full scope of practice laws in 2017. The growth of NP/PAs as buprenorphine providers suggests that they could serve a crucial role in expanding access to OUD treatment nationally.

EXPECTATIONS AND EXPERIENCES WITH PRESCRIBING CLINICIANS AMONG SHORT-STAY PATIENTS IN SKILLED NURSING FACILITIES

Kira Ryskina¹; Kierra A. Foley¹; Jason H. Karlawish¹; Joshua Uy¹; Briana Lott²; Erica Goldberg¹; Nancy Hodgson¹. ¹University of Pennsylvania, Philadelphia, PA; ²Veteran Affairs, Philadelphia, PA. (Control ID #3169816)

BACKGROUND: One in four Medicare beneficiaries discharged from hospitals to skilled nursing facilities (SNFs) for post-acute care (short-stay) are re-hospitalized or die within 30 days. While prescribing clinicians (physicians, nurse practitioners, and physician assistants) are considered integral to improving care coordination and transitions in care, little is known about the role of SNF prescribing clinicians in the experience of patients who transition from hospitals to post-acute care in SNFs. Our objectives in this study were: 1) to describe patient and caregiver expectations and experiences with SNF prescribing clinician care among patients receiving post-acute care in these facilities, and 2) to elicit thematic differences in patient and caregiver experiences among patients with and without cognitive impairment as well as among white patients and black patients.

METHODS: We conducted a qualitative study using semi-structured patient interviews at five diverse (i.e., size, setting, and prescribing clinician staffing) SNFs between January and August 2018. Forty-eight patients transferred to the SNFs for short-term care 5-10 days prior to the interview were eligible to participate. All participants were asked to identify a primary caregiver who was contacted by telephone to complete the interview as well. Thematic analysis of the transcripts was performed to detect recurrent themes and divergent ideas with a focus on modifiable prescribing clinician-level factors that might improve patient experience with post-acute care in SNFs. Analysis was stratified by patient cognitive impairment (measured by the Montreal Cognitive Assessment (MOCA) test) and race. Member checks were conducted as a validation technique.

RESULTS: The major theme that emerged was misleading expectations about the prescribing clinician (for example, patients expected to continue seeing the doctor who was treating them during the preceding hospitalization). A majority of subjects (85%) reported transient interactions with their SNF prescribing clinician. Most (95%) had limited knowledge of the prescribing clinician(s) in SNFs and 60% reported feeling disempowered to discuss their care with the clinician(s). Patients with lower MOCA scores and minorities were more likely to report feeling disempowered.

CONCLUSIONS: Our findings identify specific areas for improvement in the delivery of care for patients discharged to SNF for post-acute care after a hospitalization. In the context of growing reliance on SNFs as a post-acute care destination after hospital discharge, especially among patients with cognitive impairment, and increasing specialization of prescribing clinicians in SNF practice (i.e. the emergence 'SNFists'), better understanding of patient and caregiver expectations of prescribing clinician care in SNFs is needed to inform policy and local practices related to prescribing clinicians in SNFs.

EXPERIENCES OF SEX TRAFFICKING VICTIMS IN HEALTHCARE SETTINGS

Joseph Shin¹; Vivian Pender³; Karen Mathewson⁴; Monika M. Safford².
¹Weill Cornell Medicine, Brooklyn, NY; ²Weill Cornell Medical College, New York, NY; ³Weill Cornell Medicine, New York, NY; ⁴New York University, New York, NY. (Control ID #3183293)

BACKGROUND: It is estimated that up to 88% of sex trafficking victims in the United States have had contact with one or more health professionals during the period of time they were trafficked. As victim identification remains low, little is known about the characteristics of these healthcare encounters or the experiences of victims. The purpose of this study is to explore the experiences of domestic sex trafficking victims in order to identify potential barriers to and opportunities for improved victim identification, disclosure, and linkage to appropriate services.

METHODS: A qualitative study involving a series of focus groups with survivors of domestic sex trafficking was conducted. Study participants were English-speaking women, age 18 years or older, survivors of child and adolescent domestic sex trafficking. Participants were recruited from a single community-based organization in New York City. Transcripts of the focus groups were analyzed using a grounded theory approach, and key concepts and themes were identified.

RESULTS: Four focus groups were conducted including a convenience sample of 28 total participants with a mean age of 22 (range: 18-27), and an average age of initiation into trafficking of 14.8 years (range: 11-18). Participants were mostly Black (n=13), Hispanic (n=5), and Mixed-race (n=8). They reported seeking healthcare from a wide variety of locations and practice settings, for a variety of medical problems and symptoms: 1) physical trauma/injuries, 2) mental health, 3) gynecologic and reproductive health, 4) substance-use related and 5) neurologic. Six key themes emerged that characterized their healthcare experiences. Generally, trafficking victims experience high levels of 1) healthcare fragmentation; 2) stigma and disrespect during healthcare visits; 3) high burdens of disclosing trafficking experience; 4) narrowed expectations for effective assistance; 5) conflict between self-perception of agency and victimization; and 6) a greater receptivity to peer support.

CONCLUSIONS: Although sex trafficking victims appear to have frequent contact with healthcare providers, these encounters are often characterized by negative experiences and interactions. These may represent major contributors to the current gaps in care and limited effectiveness of screening and service linkage strategies for trafficking victims. Interventions that enhance trauma-informed care, stigma-free engagement, and peer support while reducing the personal, legal and administrative burdens of disclosure and perceived threats to agency or security may lead to improved victim identification and assistance.

EXPERT RECOMMENDATIONS ON IMPROVING TRAUMA-SENSITIVE PRIMARY CARE DELIVERY FOR WOMEN VETERANS WITH HISTORIES OF MILITARY SEXUAL TRAUMA

Alicia Bergman¹; Elizabeth M. Yano²; Joya G. Chrystal³; Bevanne Bean-Mayberry⁴; Alison B. Hamilton³. ¹VA Greater Los Angeles, North Hills, CA; ²VA Greater Los Angeles Healthcare System, Sepulveda, CA; ³VA Greater Los Angeles Healthcare System, Los Angeles, CA; ⁴VA Greater Los Angeles HSR&D Center, Sherman Oaks, CA. (Control ID #3184446)

BACKGROUND: The rate of military sexual trauma (MST) among regular primary care (PC) women Veteran (WV) users in the VA is high. History of sexual trauma is associated with depression, anxiety, PTSD, adverse impacts on medical management of chronic conditions, and discomfort with routine preventive exams. Ensuring delivery of VA's medical home care that is sensitive to sexual trauma histories is therefore critical. However, there is a need for additional expert guidance for

primary care providers on the delivery of trauma-sensitive primary care. Our goal was to explore VA subject matter expert (SME) perspectives on critical aspects and best practices of trauma-sensitive primary care.

METHODS: We conducted interviews with 30 VA SMEs (Women's Health Medical Directors [n=10], Military Sexual Trauma Coordinators [n=10], and Women's Mental Health Champions [n=10]) in 10 VA Medical Centers regarding their experiences with and expertise on trauma-sensitive PC. Interviews were recorded, transcribed, and analyzed to identify trauma-sensitive best practices for PCPs to promote feelings of physical and psychological safety during general PC exams.

RESULTS: Participants discussed various verbal and non-verbal strategies PC providers can use in general exams to promote feelings of physical safety and psychological safety among WV patients who have histories of sexual trauma. Strategies for physical safety included ensuring the patient is fully clothed during discussions, giving the patient a wide girth of space, asking permission before any physical contact, not coming up to the patient from behind, and proactively asking about the patient's comfort regarding specialty procedures before making a referral (e.g., if sedation is ok). Participants also shared numerous strategies that PC providers can use to facilitate feelings of psychological safety. For example, displaying good bedside manners was described as important to building a foundation of trust and positive emotions (e.g., making eye contact, greeting patient in a comforting manner), as was giving the patient options for how to proceed with care (e.g., "If you prefer that a female provider do A, B, and C, that's ok with me"). Additional strategies for encouraging emotional comfort included calling patients by name, using shared decision-making, making sure the patient is ok with medical students observing exams or procedures, and employing careful and intentional (non-judgmental) phrasing for asking questions and recommending tests (e.g., STD or HIV test).

CONCLUSIONS: Participants highlighted various concrete trauma-sensitive tips and strategies for how VA PC providers can promote feelings of physical and emotional safety among WV patients who have histories of sexual trauma. Increasing awareness of pragmatic trauma-sensitive care strategies can improve PC provider sensitivity and care delivery. The translation of recommended strategies into practice-wide changes will require multilevel action to operationalize and implement them.

EXPLORING HOW SCREENING AND REFERRAL FOR SOCIAL DETERMINANTS OF HEALTH AFFECTS USAGE OF HOSPITAL AND COMMUNITY RESOURCES THAT HELP WITH SOCIAL NEEDS: A PILOT STUDY

Pablo Buitron de la Vega¹; Kelsi Carolan²; Marna Stack⁴; Nancy R. Kressin⁵; Stephanie Losi³; Linda Sprague Martinez²; Alana Ewen³; Haeyeon Hong⁷; Daniel Sylvester⁷; Heloisa DeCarvalho⁶; Arvin Garg³. ¹Boston Medical Center / Boston University, Dorchester, MA; ²Boston University School of Social Work, Boston, AL; ³Boston Medical Center, Boston, MA; ⁴Boston University School of Medicine, Boston, MA; ⁵Dept of Veterans Affairs and Boston University, West Roxbury, MA; ⁶Boston University School of Medicine, Chelsea, MA; ⁷Boston University, Boston, MA. (Control ID #3172757)

BACKGROUND: Social determinants of health (SDOH) affect risk and outcomes from chronic diseases. Yet, there have been few systematic and sustained clinical strategies and processes for addressing SDOH. An Electronic Health Record-based SDOH screening and referral model called THRIVE, adapted from the WECARE model for pediatrics, has been implemented at Boston Medical Center (BMC) adult primary care since October 2017. This study examined the potential impact of THRIVE on usage of

Hospital and Community Resources that Help with Social Need among BMC adult primary care patients.

METHODS: Mixed methods telephone survey to explore usage of resources that help with social needs. 57 adult patients (English and Spanish speaking) that went through THRIVE from October 2017 to March 2018 were called 4-8 weeks after presenting to their primary care visit. A comparison group of 37 participants that presented to BMC primary care from July to October 2017 (prior to THRIVE implementation), were also called.

RESULTS: Of the 57 THRIVE participants, 15 (26%) endorsed the need for assistance connecting with resources (including housing, food, medicines, transportation, utilities, employment and education). Of the 57 patients, 14 (25%) attempted to connect with some type of resource and 17 (30%) indicated that they received help with a social need since their last visit. Of the 37 surveyed patients in the comparison group, two (5%) indicated that their doctor had referred them to resources, 5 (14%) attempted to connect with some type of resource and 4 (11%) indicated that they have received help with a social need since their last visit. THRIVE participants reported high levels of difficulty connecting with housing resources. Additionally, they described having an easier time connecting with BMC resources including the BMC pharmacy and food pantry. Qualitative analysis of open ended questions for both groups showed that reaching out by phone but not hearing back from resources was the main challenge when trying to receive help. Additional obstacles included having to reapply for the same resources multiple times, language barriers, health and transportation barriers and importantly, limited knowledge of available resources. The most consistent piece of feedback that both groups provided was that healthcare professionals should ask patients about SDOH resource needs - and provide resource or referral information - as part of primary care visits.

CONCLUSIONS: The THRIVE participants attempted to connect with resources more often than those in the control group. Although both group participants attempting to connect successfully received resources, and several described Boston Medical Center itself as a source of assistance, patients experience multiple obstacles to obtaining resource assistance. The results indicate that patients are interested in physicians and/or healthcare professionals proactively asking about potential resource needs as part of office visits.

EXPLORING MEDICATION ADHERENCE FOR OHIO MEDICAID ENROLLEES WITH HYPERTENSION IN AN ERA OF TIGHTER TARGETS: WHERE ARE THE OPPORTUNITIES FOR THE GREATEST IMPACT?

Shari Bolen^{1,2}; Suparna Navale²; Siran Koroukian²; Michelle Menegay³; Douglas Einstadter⁴; Jackson Wright²; Randall D. Cebul²; Adam T. Perzynski⁵; Catherine Sullivan⁵; Wanda Ali-Matlock⁶; Jonathan Lever⁶; Michael Konstan²; Dushka A. Crane³; Allison Lorenz²; Michael Nau³; Melissa Nance⁷; Stephen Albanese⁷; Donald Wharton⁷; Mary Applegate⁷. ¹MetroHealth/Case Western Reserve University, Cleveland, OH; ²Case Western Reserve University, Cleveland, OH; ³Ohio Colleges of Medicine Government Resource Center, Columbus, OH; ⁴MetroHealth Medical Center, Cleveland, OH; ⁵Case Western Reserve University at MetroHealth, Cleveland, OH; ⁶Better Health Partnership, Cleveland, OH; ⁷The Ohio Department of Medicaid, Columbus, OH. (Control ID #3185055)

BACKGROUND: Although prior studies have utilized claims data to evaluate medication adherence, utilization and cost for adults with hypertension, few studies have combined clinical and administrative data to explore factors associated with medication adherence and blood pressure (BP) control. In an era of tigher BP targets, this study combines recent

electronic health record (EHR) data from Ohio safety net primary care clinics linked with Medicaid claims data to explore these relationships and provide potential opportunities for improving medication adherence and BP control.

METHODS: Ohio Medicaid enrollees aged 64 or younger with a diagnosis of hypertension and seen at one of six safety net primary care clinics participating in a statewide hypertension quality improvement project during 2017-18 were included in this retrospective observational study. We conducted 2 sequential logistic regression analyses: 1) a baseline analysis for medication adherence adjusted for age, race, sex, selected comorbidities, and days supply of medication; and 2) an analysis for BP control with the same adjustments and also adjusted for medication adherence. We defined medication adherence as a medication possession ratio (MPR) of 80%.

RESULTS: Of 1,038 Ohio Medicaid enrollees seen at one of 6 clinics during 2017- 18, 56% were under good blood pressure (BP) control (most recent BP<140/90 mm Hg). Patients had a mean age of 50 (SD 10) and were diverse (46% African American, 48% white, and 58% female). About 1/3 of uncontrolled patients had no claims for BP medications during the study period. Of 729 patients who had filled 1 BP medications, 68% were considered adherent (MPR 0.8). Those with controlled BP had higher medication adherence compared to those with uncontrolled BP (75% vs 57% respectively). Due to coverage policies, most patients (88%) received a 30-day supply of their BP medications, with only 10% and 2% of patients receiving > 30-day or 90-day supply respectively. In adjusted models, medication adherence was associated with better BP control (OR 2.1; 95% CI 1.5-2.9). Age was positively associated with medication adherence (OR 1.8; 95% CI 1.0-3.2 comparing 55-64 versus 18-34 years) but was not associated with better BP control after adjusting for adherence. Receiving more than a 30 day supply of BP medication had a suggestion of an association with better medication adherence (OR 1.3; 95% CI 0.8 to 2.3), and was associated with better BP control (OR 2.0; 95% CI 1.2-3.3). African Americans (versus whites) had lower medication adherence and lower BP control (OR 0.5; 95% CI 0.3-0.7 and OR 0.6, 95% CI 0.4-0.8 respectively).

CONCLUSIONS: Non-adherence was common and strongly associated with worse BP control. Programs targeted at younger hypertensive adults and African Americans with uncontrolled BP could have the greatest impact. The effect of changing policy to permit a 90-day supply of medications should be further evaluated.

EXPLORING PATIENT PERSPECTIVES ON THE FEASIBILITY AND ACCEPTABILITY OF MEDICATION ADHERENCE SUPPORT SERVICES FOR HYPERTENSION AT A PRIVATE HOSPITAL IN KAMPALA, UGANDA

Rachel Wilkinson¹; Evan Garden¹; Rose C. Nanyonga⁴; Allison Squires²; Jeremy I. Schwartz³; David J. Heller^{1, 1}. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²New York University, New York, NY; ³Yale School of Medicine, New Haven, CT; ⁴Clarke International University, Kampala, Uganda. (Control ID #3185654)

BACKGROUND: Hypertension (HTN) is the leading risk factor for death not only in the United States but also in low- and middle-income countries. In Uganda, HTN affects 24% of adults, but the primary care system has struggled to control it. Only 7.7% of Ugandans with hypertension are aware of their diagnosis, and less than half of those persons receive treatment with medication. Moreover, less than half of persons on HTN treatment achieve blood pressure control, suggesting substantial barriers to medication adherence even among patients with adequate care access. As HTN treatment programs scale up across Uganda, identifying and solving barriers to adherence within these programs becomes increasingly crucial. This study explored patient perspectives on acceptability of medication adherence interventions for HTN at International Hospital Kampala (IHK) in Uganda.

METHODS: Using a qualitative descriptive design, we conducted 42 key informant interviews with hypertensive patients probing beliefs about the causes of medication nonadherence, and identifying viable adherence support tools to mitigate them. We explored the acceptability of support strategies validated in similar contexts, such as: daily text reminders, educational materials on hypertension, monthly group meetings (i.e. "adherence clubs") led by patients or providers, one-on-one appointments with providers, and modified drug dispensing at the hospital pharmacy. An open coding approach using NVIVO software structured the analysis. Themes and categories emerged iteratively and were solidified through consensus building processes.

RESULTS: Two themes emerged regarding causes of and solutions to adherence barriers: medication access and care engagement. Engagement barriers included lack of HTN symptoms, lack of peer or family support, interest in alternative or traditional medicine, forgetfulness, and disease denial; access barriers included distance to clinics and medication cost and availability. Patients were most supportive of interventions designed to further engage them in care, such as educational materials and adherence clubs. Patients praised their convenience (i.e. educational materials are portable and customizable) and peer support (i.e. learning from successfully adherent peers). Text message reminders and one-on-one counselling also received support because of convenience and high levels of provider trust respectively.

CONCLUSIONS: Patients are motivated to control their blood pressure and are supportive of interventions designed to actively engage them in their care, suggesting that adherence clubs and educational materials may be successful tools for improving adherence in this population. Pilot testing of adherence clubs is underway; further work will directly evaluate its impact on blood pressure control. If effective, these interventions have the potential to improve medication adherence in similar contexts globally.

EXPLORING PHYSICIAN EXPERIENCES ENGAGING CAREGIVERS IN THE SAFETY-NET

Wagahta Semere¹; Anupama Cemballi¹; Alejandra Casillas²; Neda Ratanawongsa¹; Shobha Sadasivaiah¹; Courtney Lyles¹. ¹University of California San Francisco at Zuckerberg San Francisco General Hospital, San Francisco, CA; ²University of California Los Angeles, Los Angeles, CA. (Control ID #3185330)

BACKGROUND: Physicians experience communication gaps with caregivers, which create care coordination challenges that may be compounded when caring for patients in the safety-net who have limited resources and language barriers. However, knowledge of physician interactions with caregivers in this setting is limited. The objective of this study is to explore physician experiences with caregivers in the safety-net.

METHODS: We conducted 40-60 minute semi-structured interviews with 16 primary care providers from three California safety-net hospital systems (San Francisco Health Network, Los Angeles Department of Health Services, and Alameda Health System). Interviews explored provider engagement with caregivers in the safety-net setting. We analyzed interview transcripts using both deductive (i.e., guided by the interview guide) and inductive approaches (i.e., open coding) then established consensus regarding major themes and exemplary quotes.

RESULTS: Of 16 primary care providers interviewed, 4 were geriatricians. We identified four themes describing provider experiences with caregivers: (1) the diversity of caregivers, (2) visit and inter-visit communication strategies, (3) engaging caregivers in patient care, and (4) language and literacy barriers (Table). Providers noted a distinction between formal, paid caregivers

and informal (often family) caregivers that coordinate patient care. Most interactions with caregivers were described in the context of clinic visits, where providers frequently encountered language and literacy barriers. Providers expressed that caregivers in the safety-net displayed limited confidence engaging in care management.

CONCLUSIONS: Providers in the safety-net understood caregivers to be a diverse group, including both formal and informal caregivers, providing multiple supportive roles on behalf of patients. In order to better leverage caregivers in patient care, providers in the safety-net may benefit from targeted resources to overcome language and literacy barriers and to specifically empower caregivers.

EXPLORING PROVIDER PERSPECTIVES ON THE FEASIBILITY AND ACCEPTABILITY OF MEDICATION ADHERENCE SUPPORT SERVICES FOR HYPERTENSION AT A PRIVATE HOSPITAL IN KAMPALA, UGANDA

Evan Garden¹; Rachel Wilkinson¹; Rose C. Nanyonga²; Allison Squires³; Jeremy I. Schwartz⁴; David J. Heller^{1, 1}. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Clarke International University, Kampala, Uganda; ³New York University, New York, NY; ⁴Yale School of Medicine, New Haven, CT. (Control ID #3185640)

BACKGROUND: Hypertension (HTN) is the most common contributor to mortality in Uganda, and cardiovascular disease (CVD) is the leading cause of death. Although access to HTN screening and treatment is a major contributor to this burden, medication adherence is also a barrier to disease control. Previous work demonstrates that primary care providers in Uganda struggle to aid patients with HTN medication adherence, as patients lack symptoms and disease information, and face financial obstacles. Several interventions to improve HTN medication adherence in sub-Saharan Africa (SSA) exist in similar settings, but the feasibility and acceptability of these options for care providers, especially within the private sector, is unclear.

METHODS: Using a qualitative descriptive approach, we explored provider perspectives on challenges to HTN medication adherence, as well as the feasibility and acceptability of various forms of medication adherence support. Data collection occurred through key informant interviews with 15 providers (8 medical officers, 7 nurses) at International Hospital Kampala (IHK), a private hospital in Uganda. We specifically asked about potential interventions, including daily SMS (text) reminders; educational materials; monthly group meetings ("adherence clubs") led by patients or providers; one-on-one appointments with providers; and modifying drug dispensing at the hospital pharmacy. Two coders analyzed the interviews using a general content analysis approach, where themes and categories emerged iteratively.

RESULTS: Providers' beliefs on adherence determinants centered on two themes: patient access (i.e. cost, distance from care centers) and patient engagement (i.e. lack of knowledge of HTN causes and treatment, lack of support systems), aligning with patients' views in related interviews. Providers especially supported adherence clubs, citing improved patient engagement through peer support and increased provider-patient interactions. They also endorsed patient educational materials due, but cited limited patient literacy as a barrier. Daily SMS reminders were deemed convenient, particularly for patients who lived far from IHK. Providers considered staffing concerns as the major barrier to implementing these interventions, but also cited program finances, patient participation, and scheduling concerns.

CONCLUSIONS: Providers viewed adherence support interventions as feasible and acceptable additions to HTN care at IHK, but cited financial cost and human resources as barriers. Providers' views regarding HTN

adherence initiatives centered on both improving access to care and increasing patient engagement, whereas patients' beliefs centered primarily on engagement. HTN adherence clubs, developed based on patients' and providers joint perspectives, could substantially improve patient engagement with and access to HTN care; design and implementation of this initiative at IHK is ongoing.

FACTORS AFFECTING HEALTHY EATING AND EXERCISE AMONG LESBIAN AND BISEXUAL LATINA WOMEN AND DISCUSSING HEALTHY LIFESTYLE WITH THEIR PRIMARY CARE PROVIDERS

Julie Grutzmacher¹; Jessica I. Mora¹; Katherine Ordóñez¹; Monica Vela²; Seeba Anam¹; Arshiya A. Baig¹. ¹University of Chicago, Chicago, IL;

²University of Chicago Pritzker School of Medicine, Chicago, IL. (Control ID #3177734)

BACKGROUND: Latina lesbian and bisexual women experience high rates of overweight and obesity compared to their white counterparts; however few studies have explored the factors that influence healthy eating and exercise in this population and their experiences discussing healthy lifestyle with their primary care providers.

METHODS: We conducted semi-structured one-on-one interviews in English and Spanish with 20 lesbian and bisexual cisgender Latina women in Chicago. Questions focused on identity and intersectionality; relationships with healthcare providers, the mechanism of disclosure and shared decision making; particularly involving decisions about healthy and unhealthy diet, and exercise. Examples of these questions include: "Tell me about how your identities (racial/ethnic and sexual orientation/gender identity) affect your thoughts about healthy and unhealthy eating," and "Have you ever talked with a healthcare provider about healthy and /or unhealthy eating, exercise and/or body image?" The interviews were later transcribed verbatim. A codebook was developed, transcripts were double coded and entered into NVIVO, and themes were analyzed using modified Grounded Theory. Fifteen of the interviews were conducted in English and five in Spanish.

RESULTS: Of the 20 participants, the average age was 33 years old. Fourteen or 70% of them identified as lesbian and six (30%) identified as bisexual, pansexual, or queer. All of them identified as a cisgender woman and as Latina/Hispanic. Participants indicated that cultural traditions and norms (i.e. carnitas, tortillas, chorizo) can pose as barriers to healthy eating patterns. On the other hand, some participants stated that being part of the queer community has endorsed healthier eating patterns and exposed them to healthy foods not endemic to their popular cultural traditions (i.e. vegan diets). With regards to physical activity, participants' cultural heritage, comfort and safety, and stereotypes about certain sports (i.e. soccer or softball) influenced their decisions around physical activity more so than their sexual minority identities. Participants described the stress of having to educate their providers on queer lifestyle, which they described as awkward and wasting time where they could otherwise be asking questions of their own. The recommendations were for providers to take a patient-centered, individualized counseling approach and engage them in dialogue about healthy eating and exercise.

CONCLUSIONS: Identity and behavior is inextricably connected. Participants' decisions around eating and exercise were heavily impacted by their multiple intersecting identities (race/ethnicity, gender, sexual orientation, SES and employment status). Raising awareness among providers about intersectionality and factors that influence patients' decision making is an essential place to start for reducing disparities and further supporting the health equity of this population.

FACTORS AFFECTING YOUNG GAY MEN'S PREFERENCE FOR SEXUAL ORIENTATION- AND GENDER IDENTITY-CONCORDANT PROVIDERS

Stephanie E. McLaughlin²; Cary Blum²; Angelina Gomes²; Carolyn Drake²; Colleen Gillespie²; Richard Greene²; Perry Halkitis¹; Farzana Kapadia¹. ¹New York University, New York, NY; ²New York University School of Medicine, New York, NY. (Control ID #3184662)

BACKGROUND: A relative dearth of literature exists on preferences of young gay male patients have regarding the sexual orientation and gender identity (SOGI) of their healthcare providers. Further research in this area is warranted to better serve the young MSM population.

METHODS: *Data collection:* A sample of 800 young adult gay men completed a brief survey on healthcare preferences between 2015-2016. Participant inclusion criteria were: age 18-29, male gender, self-identified gay sexual orientation, living in US for 5+ years, and being a resident of the New York City metropolitan area. Only participants who reported having a current PCP provided information on preferred PCP characteristics (i.e. male and/or LGBT). *Data analysis:* Multivariable logistic regression models were built to assess factors associated with participant preference for an LGBT or male PCP. Covariates for inclusion were considered based on prior literature as well as those identified as significant in bivariate logistic regression analyses. Backward model selection with variance inflation factor (VIF) analysis was used to eliminate collinearity and arrive at the most parsimonious models.

RESULTS: In this sample, n=614 men (77%) reported having a PCP. Of those 614 with a PCP, 42% indicated a preference for male PCP, 36% preferred a gay or LGBT PCP, and a total of 20% preferred a male-LGBT provider. A preference for consolidated care and distrust in the health system were associated with preference for a sexual orientation concordant PCP. Preference for sexual orientation concordance was strongly associated with preference for gender concordance, and vice versa. Minority race was also found to be associated with preference for a gender-identity concordant (male) PCP.

CONCLUSIONS: Gay men who wish to discuss their overall health and sexual health with their primary care provider (ie, receive consolidated care) tend to prefer a LGBT provider. This is also true of gay men who distrust the healthcare system, possibly because they anticipate these providers will provide more culturally sensitive care. A surprising association was found between minority racial background and preference for a gender concordant provider. Further research is warranted to explore the factors giving rise to this finding.

Table 2. Summary of OLS regression predicting preference for PCP SOGI concordance

| Variable | Prefer gay or LGBT PCP OR (95% CI) | Prefer male-identified PCP OR (95% CI) |
|----------------------------|---------------------------------------|---|
| Age 24-29 | 1.02 (0.703-1.47) | 0.981 (0.684-1.40) |
| Minority race | 0.865 (0.537-1.39) | 2.02 (1.24-3.27) *** |
| HIV positive | 0.981 (0.684-1.40) | 1.20 (0.734-1.97) |
| Distrust in health system | 1.59 (0.922-2.73) * | 0.928 (0.540-1.59) |
| Prefer consolidated care | 1.72 (1.01-2.92) ** | 0.958 (0.587-1.50) |
| Prefer male-identified PCP | 2.61 (1.81-3.74) *** | N/A |
| Prefer gay or LGBT PCP | N/A | 2.60 (1.81-3.37) *** |

FACTORS ASSOCIATED WITH INCREASED RISK PERCEPTION FOR DEVELOPING TYPE 2 DIABETES IN WOMEN WITH RECENT GESTATIONAL DIABETES

Jacinda M. Nicklas¹; Geraldine Skurnik²; Ellen W. Seely². ¹University of Colorado School of Medicine, Aurora, CO; ²Brigham and Women's Hospital, Boston, MA. (Control ID #3184760)

BACKGROUND: Women with gestational diabetes (GDM) have a 30-70% risk for developing type 2 diabetes. Although women with a history of GDM can decrease their risk for type 2 diabetes through weight loss and increased physical activity, prior studies indicate that many women with a history of GDM do not engage in risk reducing behaviors. Perception of personal risk for type 2 diabetes may influence participation in these risk reduction behaviors. We sought to identify factors associated with increased risk perception for developing type 2 diabetes in women with recent gestational diabetes.

METHODS: For the Balance After Baby Intervention 2 (BABY-2) trial, we recruited women with GDM during pregnancy or just after delivery. We asked participants to come in at 6 weeks postpartum for a baseline study visit. We measured weight and height, and women completed questionnaires detailing demographic, family history and medical history, as well as the Edinburgh Postnatal Depression Scale and the Risk Perception Survey for Developing Diabetes. All measurements and questionnaires were conducted before randomization into the intervention trial. For this analysis we included all women answering a risk perception question about their risk for getting diabetes within the next 10 years. We then categorized women into almost no or slight perceived chance vs. moderate or high perceived chance for developing diabetes. We conducted univariate analyses, and modeled the odds of increased risk perception for type 2 diabetes using multivariable logistic regression. We included all variables with a p value <.2 from the univariate analyses in the initial model, and then used backward selection to fit a final model.

RESULTS: Our study included 181 women (mean 33 ± 5.3 years; 48% White, 17% African-American, 22% Asian, 13% other race, with 35% Hispanic). 48% of women spoke a primary language at home that was not English and 54% of women had graduated from college. 31% of women reported household incomes of <\$35,000 per year. 28% had had GDM in a previous pregnancy, and 43% had a first degree relative with type 2 diabetes. The mean BMI at the study visit was $31.3 (\pm 5.9)$ kg/m². Factors included in the final model associated with a moderate to high perception of risk for diabetes included having a first degree relative with type 2 diabetes (OR 2.9, 95% CI 1.5-5.5) and identifying as Hispanic or Latino (OR 2.5, 95% CI 1.3-4.9). Having a history of GDM in a previous pregnancy and education status were not retained in the final model.

CONCLUSIONS: Among women with recent gestational diabetes, identifying as Hispanic/Latino and having a first degree relative with type 2 diabetes were associated with increased risk perception for developing diabetes. Further research should address how risk perception in this population influences participation in interventions designed to reduce risk for type 2 diabetes and whether employing unique strategies addressing risk perception can improve outcomes.

FACTORS ASSOCIATED WITH LONG-TERM RETENTION IN BUPRENORPHINE BASED ADDICTION TREATMENT PROGRAMS: A SYSTEMATIC REVIEW

Amy J. Kennedy³; Jessica S. Merlin³; Charles B. Wessel²; Rebecca Levine¹; Iman Hassan³; Kendall Downer¹; Megan Raymond⁴; Deborah Osakue¹; Jane M. Liebschutz³. ¹University of Pittsburgh Medical Center, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA; ³University of Pittsburgh, Pittsburgh, PA; ⁴University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #3170853)

BACKGROUND: The average length of opioid agonist therapy with buprenorphine (BUP) for opioid use disorder is less than 6 months. We conducted a systematic review to determine what treatment level factors (dose, treatment setting and behavioral therapies) were associated with longer retention in BUP treatment.

METHODS: We searched Medline, Embase and the Cochrane Database of Systematic Reviews in February 2018. Articles were restricted to randomized-controlled trials on human subjects, written in English, and contained >24 weeks of objective data on retention in BUP treatment. We assessed whether dose of BUP, treatment setting, or co-administration of behavioral therapy were associated with retention rates.

RESULTS: Over 14,000 articles were identified. Twenty-two articles met final inclusion criteria, describing a total of 13 studies (Figure 1). There was significant heterogeneity in the measurement of retention. Measures included days in treatment (n=10), urine drug testing for BUP (n=2), and a combination of days in treatment and plasma level testing for BUP (n=1). Three studies compared doses of BUP between 1-8mg and showed significantly higher rates of retention with higher doses (p-values <0.01). All other studies in our review utilized maintenance BUP doses between 8mg-24mg daily, without comparison. No study found a significant difference in retention between BUP alone and BUP plus behavioral therapy (p-values > 0.05). Starting BUP prior to initiation in outpatient treatment programs (inpatient induction or within criminal justice settings) was significantly associated with retention in BUP treatment (p-values 0.009 and 0.005 respectively).

CONCLUSIONS: Setting of treatment initiation and higher BUP dose are associated with improved long-term treatment retention. More data on BUP treatment programs is needed as well as a standardized approach to defining retention in BUP treatment programs.

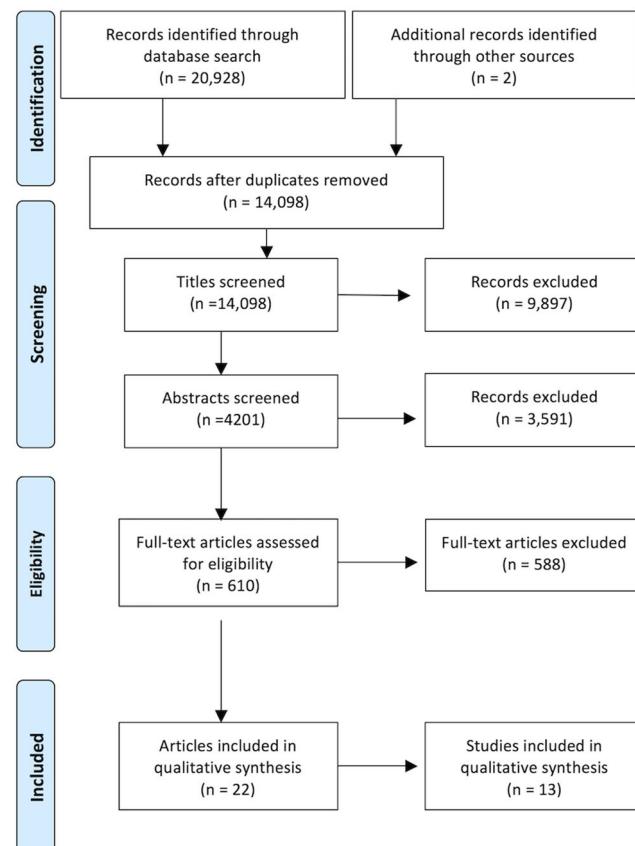

Figure 1. Flow diagram of the selection process for study inclusion.

FACTORS ASSOCIATED WITH OPIOID DISCONTINUATION IN CHRONIC OPIOID THERAPY

Jason M. Glanz^{1, 2}; Stanley Xu¹; Komal J. Narwaney¹; Susan M. Shetterly¹; Jo Ann Shoup¹; Jennifer Lyden^{3, 4}; Ingrid A. Binswanger^{1, 4}. ¹Kaiser Permanente Colorado, Denver, CO; ²Colorado School of Public Health, Aurora, CO; ³Denver Health, Denver, CO; ⁴University of Colorado School of Medicine, Aurora, CO. (Control ID #3186067)

BACKGROUND: There is limited evidence on the safety and effectiveness of opioid tapering practices in pain management. In addition, there is a lack of data describing tapering practices and outcomes in routine clinical care. We sought to examine characteristics associated with opioid discontinuation among patients receiving chronic opioid therapy (COT).

METHODS: We conducted a matched cohort study using electronic health record data from an integrated health system in Colorado. We identified health plan members 18 years between 2006 and 2017, who had 90 days continuous enrollment and received COT (3 opioid prescriptions in 90 days). Among these patients, we identified periods of opioid discontinuation, defined as 3 months without any opioid dispensings. Using calendar time, patients who had been discontinued were frequency matched to patients who did not discontinue. We conducted two logistic regression analyses examining 11 demographic and clinical characteristics. The first compared patients with 1 period of discontinuation to patients without a discontinuation. The second analysis compared patients who had a period of discontinuation but resumed opioid therapy to patients who remained discontinued while enrolled in the health plan.

RESULTS: We identified a cohort of 14,419 patients who received COT during the observation period. Over a mean follow-up of 4.8 years, 8,518 (59%) were never discontinued, 2,740 (19%) stayed discontinued, 2,234 (15%) were discontinued and resumed opioids, and 927 (6%) were discontinued and disenrolled from the health plan. In the first analysis, the following variables were positively associated with being discontinued: young age, white, history of overdose, mental health diagnosis, alcohol and drug use disorders, long acting opioids, and low opioid dose (Table). In the second analysis, the following variables were positively associated with sustained discontinuation: young age, drug use disorder, and low opioid dose. Receipt of a benzodiazepine was negatively associated with sustained discontinuation.

CONCLUSIONS: Among patients on COT, periods of opioid discontinuation were common. Discontinued patients frequently resumed opioids, and baseline patient characteristics were significantly associated with opioid discontinuation patterns. The results suggest that it may be easier to discontinue patients on low opioid doses, and sustained discontinuation may be difficult with patients prescribed benzodiazepines.

FACTORS ASSOCIATED WITH STATE LEGISLATOR SUPPORT FOR MEDICAID WORK REQUIREMENTS

Jane M. Zhu¹; Renuka Tipirneni²; David Jones³; Michael Fichman⁴; David Grande⁴. ¹Oregon Health and Science University, Portland, OR; ²University of Michigan, Ann Arbor, MI; ³Boston University School of Public Health, Boston, MA; ⁴University of Pennsylvania, Philadelphia, PA. (Control ID #3185422)

BACKGROUND: As of early 2019, seven states (AR, IN, KY, ME, MI, NH, WI) have Medicaid waivers approved by the Centers for Medicare and Medicaid Services (CMS) to implement work or community engagement requirements in exchange for coverage, and more states are considering or seeking similar waivers. This study examined district-level demographic and socioeconomic characteristics associated with state legislators' support for Medicaid work requirements.

METHODS: Using a database from the National Conference of State Legislators (NCSL), we surveyed active state legislators (n=7,340) on their views of Medicaid policy proposals, including work requirements,

selected from approved and pending Medicaid section 1115 waiver applications. The survey instrument was pilot-tested with current state legislators and federal legislative staff to ensure policy relevance of questions and non-partisan language. Post-survey, responses were linked to demographic and socioeconomic data from the 2016 American Community Survey. We used descriptive analyses to assess views by political party, and multivariable logistic regressions to analyze legislator- and district- level factors that were associated with support for work requirements.

RESULTS: Overall, 894 (12.2%) state legislators completed the survey, a response rate consistent with those in other studies of elite-level actors. Non-respondents were more likely to be non-health care committee members, Republican, male, and from the Midwest region. Republicans were more likely than Democrats to support work eligibility requirements for Medicaid (84.8% vs. 26.7%). Supporters of work requirements tended to be Republican (OR 27.75, 95% CI: 15.69-49.08, p<0.0001), reside in rural areas (OR 2.43, 95% CI: 1.48-3.99, p<0.0001), and have higher levels of Medicaid enrollment in their districts (OR 1.34 for each higher quartile of district-level Medicaid enrollment, 95% CI: 1.04-1.71, p=0.021). Legislators who supported work requirements also tended to represent districts with higher percentages of white constituents (OR=0.68 for each higher quartile of white population, 95% CI: 0.52-0.89, p=0.004). State participation in Medicaid expansion was not associated with legislators' views on Medicaid work requirements, nor was legislator membership in a health-related legislative committee.

CONCLUSIONS: Among state legislators, support for Medicaid work requirements is more strongly associated with political party affiliation than with other legislator or district-level characteristics. As state legislators become increasingly influential health policy actors, future research should probe more deeply into how views and knowledge about specific policies are cemented, including the influence of constituencies and their needs.

FACTORS INFLUENCING PATIENTS IN MEDICALLY UNDERSERVED AREAS TO CHOOSE THE EMERGENCY ROOM INSTEAD OF PRIMARY CARE FOR NON-URGENT CONDITIONS

Rosita N. Ekem; Satya Surbhi; Leonard J. Harris; James E. Bailey. University of Tennessee Health Science Center, Memphis, TN. (Control ID #3183980)

BACKGROUND: Patients often go to the emergency department (ED) for non-urgent conditions, that can be managed in primary care (PC) settings. Past research suggests that ED care for non-urgent conditions may result in unnecessary testing, elevated costs, and missed opportunities for essential primary and preventive care. ED use for non-urgent conditions is especially prevalent in medically underserved areas (MUA). This study explored patient experiences, perceptions, barriers to PC access, and preferences regarding ED and primary care use. We also examined factors that would encourage patients with non-urgent conditions to choose primary care over ED.

METHODS: A self-administered cross-sectional survey was given to a convenience sample of adults triaged as semi-urgent or non-urgent conditions in the ED of a large non-profit healthcare system during June-July of 2018. Consent was obtained before patients completed the survey in private exam rooms. Exclusion criteria included pregnancy, cognitive impairment, non-English speaking, under police supervision, or hospital admission. The survey was designed to compare experiences in the ED and PC, collect demographics, patient perception of illness severity, and factors that affect non-urgent usage of the ED. Descriptive analyses were conducted to describe the study population, examine the most common barriers to PC access, and identify factors that would encourage patients to choose primary care over the ED.

RESULTS: Of 125 eligible patients approached for this study, 89 agreed to participate (response rate 71.2%). Participant mean age was 36.6 years. Most were female (50%), African-American (88.4%), and had 2 ED visits in the past year (56.6%). Also, 70% had less than a high school education, low health literacy (53.6%), and a yearly income of <\$20,000 (75.3%). Most patients regarded their condition as urgent (32.6%) or emergent (33.7%). One-third reported not having a PCP (35.3%) and using the ED as a usual source of care when sick (39.7%). Patients cited long wait times (31.4%), untimely appointments (29.4%), inconvenient clinic hours (21.2%), and transportation difficulties (18.8%) as barriers to care. Patients cited improved accessibility, acceptability, provider technical quality, and getting appointments on short notice as factors that would encourage use of PC.

CONCLUSIONS: Patients in MUA commonly perceive their conditions as urgent or emergent and desire patient-centered care when they need it, in convenient locations, and at low out-of-pocket cost. Difficulty contacting providers by phone, making timely appointments, long wait times, and high out-of-pocket costs are barriers that discourage utilization of PC. Patients cite that improved PC accessibility, accommodation, acceptability, and provider technical quality increased PC attractiveness. This study provides insight for health systems on how to increase value of care for medically underserved patient populations by improving access, affordability, and quality of PC.

FACULTY DEVELOPMENT IN MEDICAL EDUCATION IMPACTS CLINICIAN EDUCATORS' ROLE IDENTITY AND SENSE OF COMMUNITY

Penelope Lusk¹; Kevin Hauck¹; Verity Schaye³; Neil Shapiro⁴; Khemraj A. Hardowar⁵; Sondra Zabar³; Anne Dembitzer^{2, 1}. ¹NYU Langone, Brooklyn, NY; ²VA Health and Harbor, New York, NY; ³NYU School of Medicine, New York, NY; ⁴Dept. Of Veterans Affairs, New York, NY; ⁵NYU, New York, NY. (Control ID #3183943)

BACKGROUND: Faculty development programs (FDP) in medical education can increase clinician educators' (CE) confidence in teaching and improve their teaching skills. The impact of FDP on faculty's role as educators and sense of an educator community is less well understood. Identification with a community of educators (COE) can enhance teaching in the workplace along with personal and professional growth. We evaluated the impact of participation in the Education for Educators program (E4E) on these issues. E4E is a year-long FDP designed to enhance teaching confidence and skill in a variety of venues; improve ability to assess learners; promote an environment of academic inquiry with trainees at different levels; and create a COE.

METHODS: An annual needs assessment of key stakeholders including medical school deans, program directors, and participants forms the basis for the E4E curriculum. The program begins with a Group Observed Structured Teaching Experience (GOSTE) followed by three 3-hour workshops which pair a clinical and teaching topic. After each workshop, participants complete "commitment to change" statements and take part in peer-to-peer (P2P) observations wherein participants observe each other teaching in their usual teaching environment. The program concludes with structured debriefs and an assessment of participants' perception of their role as educators and their sense of an educator community. Participants reported how participation in E4E impacted their teaching and what new skills they implemented. Structured phone conversations assessed the same information one-year after completing the program.

RESULTS: Fifty-one CEs completed the program in two cohorts (2016-17 and 2017-18), 60% of whom were women. Participants

included 20 hospitalists and 31 subspecialists, averaging 8 years in practice (range 1-28) and spending an average of 63% of their time in patient care (range 10-100%). Thirty-eight participants (75%) completed the immediate post-program debrief sessions. Participants reported a renewed identification with their role as an educator. They cited a change in perspective to become more reflective and focused on teaching and recognized that their teaching skills can in fact be improved. Many reported time constraints as a barrier to teaching. They noted an increased identification with their COE, stating that they now had peers and mentors with whom to discuss teaching challenges. To date, phone interviews have been completed with three participants at one-year of follow-up. The preliminary results show a sustained impact on educators' roles and belonging to a COE. They also reported ongoing use of specific skills including resilience strategies, and planning teaching sessions.

CONCLUSIONS: Longitudinal FDP in medical education for CE can lead to a greater appreciation for the role of an educator, and identification with a COE. Investment in longitudinal FDP may have lasting impact on the clinical learning environment and the identity of faculty as an educator.

FACULTY DEVELOPMENT NEEDS FOR THE AMBULATORY CLINICIAN EDUCATOR: RESULTS OF THE AMBULATORY FACULTY RECRUITMENT, RETENTION, AND REMUNERATION IN GRADUATE MEDICAL EDUCATION SURVEY BY THE AAIM EDUCATION COMMITTEE

Jonathan Tolentino¹; Isitri Modak²; Margaret C. Lo³. ¹Stony Brook University, Cincinnati, OH; ²Methodist Health System, Grand Prairie, TX; ³University of Florida College of Medicine, Gainesville, FL. (Control ID #3186358)

BACKGROUND: With expansion of the Affordable Care Act, GME directors must create robust ambulatory teaching environments. Successful redesign of ambulatory education requires high-yield faculty development (FD) programs with clear understanding of the FD needs of ambulatory educators. While literature cites various FD programs, little exists on the FD priorities of ambulatory faculty. Tasked by AAIM, our descriptive survey reports key FD skills needed in ambulatory education.

METHODS: After several teleconferences and Delphi processes, AAIM Education committee members drafted a needs-assessment survey to address the barriers and strategies for effective ambulatory teaching and FD. Survey asked the value of 20 specific ambulatory FD skills and 5 specific venues to effectively teach these skills to residents in the ambulatory setting, based on 5-point Likert scale. Request for survey participation was posted bimonthly from August-Nov 2017 on listservs of APDIM, APM, SGIM and AAIM Ambulatory Faculty focus group. Participation was anonymous and voluntary. De-identified results were analyzed via descriptive statistics from STATA software. University of Oklahoma HSC provided IRB approval.

RESULTS: 217 ambulatory faculty completed the survey. Most were core ambulatory resident educators (76%) at academic medical centers (65%). [M1] Highest-valued FD skills for ambulatory teaching were bedside teaching (77.5%); clinical reasoning (76%); and goal-setting, evaluation, and feedback (71.6%). Least-valued FD skills were concept mapping (14.3%), research methods (19%), and large group teaching (20.1%). No differences exist between respondents from academic medical centers (AMC) or community-based programs for all skills except for promotion of clinician educators ($p<0.05$), which held less value to community-based faculty. Respondents preferred small group workshops as the delivery mechanism for learning most FD skills over didactic sessions, webinars, online modules, or conferences.

CONCLUSIONS: This cross-sectional survey adds to the literature by identifying high-yield ambulatory skills to help GME directors tailor their FD programs based on faculty types and engage ambulatory faculty to teach housestaff. Ambulatory FD programs should target teaching skills most useful in one-on-one precepting relationships (e.g. bedside teaching, feedback, and goal-setting/mentorship) and deliver such skills in small group interactive workshops. Survey data do not support FD skills esoteric to ambulatory educators such as concept mapping, research methods, or promotion for community-based faculty. Further work must focus on effective ambulatory FD models to teach these skills in low- and high-resource institutions.

FAMILY CAREGIVER PERSPECTIVES ON LONG TERM CARE PLANNING

Steffi Shilly¹; Vanessa Chicas¹; Jillian Shotwell¹; Caren Steinway¹; Sophia Jan². ¹Cohen Children's Medical Center at Northwell Health, New Hyde Park, NY; ²Northwell Health, New Hyde Park, NY. (Control ID #3175394)

BACKGROUND: Although many family caregivers of individuals with intellectual/developmental disabilities (IDD) worry about their relative's future, few develop solid long term care (LTC) plans. This lack of LTC planning may lead to crises and emotional trauma for concerned loved ones, unexpected dilemmas for siblings or extended families, and unwanted or inappropriate emergency placement.

METHODS: We conducted five focus groups in two states with parents and siblings of individuals with IDD. Before each focus group, participants were asked to complete a survey that included basic demographic information, the Waisman Activities of Daily Living Scale (W-ADL), and Scales of Independent Behavior-Revised, Problem Behavior Scale (SIB-R). Caregivers were asked about perceived barriers and facilitators of LTC planning and preferences for tools to promote LTC planning among families like theirs. Focus group recordings were transcribed verbatim and coded using the constant comparative method to identify major themes.

RESULTS: Twenty-seven family caregivers, 19-74 years old (mean age, 39.59), participated in focus groups. Family caregivers were predominantly female (56%) and White (81%). Caregivers resided in Delaware (44%), Pennsylvania (48%), and New Jersey (7%). Education level and yearly household income varied among family caregivers. The individuals with IDD, ages 14-40 years old (mean age, 23.24) lived in various states: Delaware (n=12, 44%), Pennsylvania (n=12, 44%), New Jersey (n=2, 7%), and Missouri (n=1, 4%). Of the individuals with IDD, 78% (n=21) identified as White, 15% (n=4) as Black, and 4% (n=1) as Asian. Almost half (48%) of the individuals with IDD had a Medicaid Waiver and 63% had 1 problem behavior. The mean W-ADL score was 1.209, meaning that most individuals need assistance with activities of daily living. Focus groups revealed that having an advocate (i.e., a support coordinator or government official), networking (such as with other caregivers), emotions (i.e., hope or fear), adverse events (i.e., eviction) and the experience or personal background of a caregiver (i.e., having a medical background) facilitated planning. Lack of information, lack of appropriate resources (i.e., medical providers inexperienced in caring for adults with IDD), emotions (i.e., uncertainty of the future), finances, and difficulty in systems navigation (i.e., difficulty obtaining Medicaid) were identified as barriers to planning. These barriers and facilitators are especially prominent when most services are lost during transition to adulthood. Family caregivers mentioned that a website would be a useful resource to help with LTC planning.

CONCLUSIONS: LTC planning is influenced by the coordination of many complex factors, including emotions, knowledge, and resources. Interventions for LTC planning may improve quality of

life, independence, and personal choice of adults with IDD and their caregivers.

FASTING STATUS OF PATIENTS UNDERGOING AMBULATORY LABORATORY TESTING

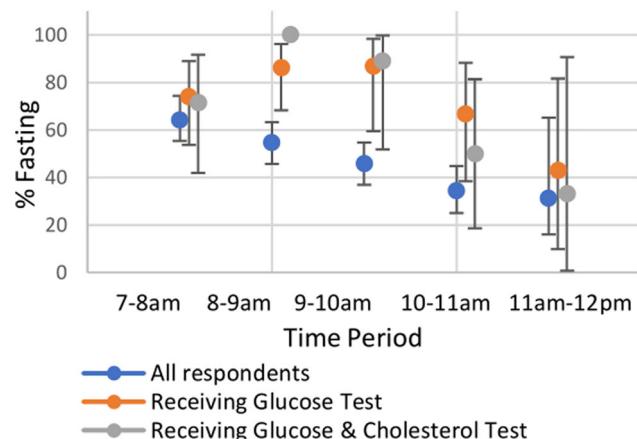

Eva Tseng¹; Jodi B. Segal²; Nisa Maruthur². ¹Johns Hopkins University SOM, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3185039)

BACKGROUND: Many population-level studies use glucose values from EMR data to identify patients with prediabetes and diabetes. Since diagnostic criteria are based on fasting glucose, investigators often assume patients are fasting, particularly if phlebotomy was in the morning. We sought to assess the validity of the assumption that outpatient, morning measurements are fasting measures.

METHODS: We surveyed adult patients (age 18 years) presenting for phlebotomy at the Johns Hopkins Outpatient Center during 7am-12pm over 2 weeks in November 2018. Patients self-administered a 4-question written survey, provided by the registration staff, about their fasting status, whether the ordering provider instructed them to fast, whether they were getting a glucose and/or cholesterol test, and what time they presented to the lab. We defined fasting status as "nothing to eat or drink 8 hours before the test except for water." We estimated a sample size of n=500 would provide a relatively tight confidence interval around the estimates (i.e., 95%CI within 5% on either side of the estimate).

RESULTS: Of 506 survey respondents, 49% reported they had fasted. Patients presenting earlier vs. later were more likely to be fasting (Figure) with 64% fasting between 7-8am compared to 31% fasting between 11am-12pm (p trend<0.001). Among those who had fasted, 49% reported their provider advised them to fast, and the remainder had not. Of those recommended by their provider to fast, the majority (91%) had fasted. Overall, more respondents who reported they were having a glucose and/or cholesterol measurement fasted (75%) than those having other testing (37%), p<0.001. The prevalence of fasting among those reporting a glucose or cholesterol measurement before 10am was 80.2% (95%CI, 71.9 to 86.9).

CONCLUSIONS: About half of patients presenting to a large, academically affiliated lab in the morning between 7am and 12pm had fasted. Glucose and cholesterol measures before 10am are more likely than not to be fasting. The reported range of fasting patients may help investigators explore the impact of misclassification of patient fasting status in population-level studies. Consideration of other variables may also enhance the accuracy of using ambulatory glucose data for population studies of diabetes and prediabetes.

FEMALE SPEAKER REPRESENTATION AT INTERNAL MEDICINE RESIDENCY CONFERENCES

Alicia M. Corwin²; Paula Chatterjee¹; Maria Yialamas³. ¹University of Pennsylvania, Philadelphia, PA; ²Brigham and Women's Hospital, Brookline, MA; ³Brigham and Women's Hospital, Boston, MA. (Control ID #3185701)

BACKGROUND: Morning reports and noon conferences are two forums that make up the backbone of internal medicine residency curricula nationwide. Invited discussants are considered master clinicians, educators and/or researchers, and often become role models for clinical trainees. While it has been documented that women are less likely to be represented at departmental grand rounds nationally, little research has evaluated exposure to female speakers at the level of clinical trainees.

METHODS: We analyzed morning report and noon conference data from three large internal medicine residency programs for the 2017-2018 academic year in Boston, MA: Brigham and Women's Hospital, Massachusetts General Hospital, and Boston Medical Center. Discussants were categorized by gender, and we performed Student's t-tests to compare the prevalence of male and female speakers at the two types of conferences.

RESULTS: The average number of female residents in the training programs was 51.5%. Morning reports were largely clinically-based case reports, while noon conferences were mainly didactic lectures. For morning reports, approximately 2/3 of speakers were men (63.7%) while 1/3 were women (36.3%). Similar results were seen for noon conferences (62.1% male and 37.9% female). These comparisons were statistically significant ($p<0.05$). The percentage of female discussants at morning report and noon conference fell 32.2% (+/- 7.4%) and 31.2% (+/- 7.9%), respectively, below the percentage of female constituents in each individual residency program.

CONCLUSIONS: Representation of female attending physicians in internal medicine residency educational conferences falls below the female composition of the resident audience. These results indicate that residents are not being exposed to a cohort of speakers that reflects their programs' gender demographics. These educational conferences often showcase clinical reasoning and medical leadership, in addition to providing an opportunity for role modeling for female trainees. Being exposed to female role models may reduce the effects of implicit bias during clinical training. Programs should examine mechanisms behind these disparities, and future research could examine whether programmatic changes impact how trainees envision medical leaders and perceived implicit biases.

FIDELITY TO KEY FEATURES OF EVIDENCE-BASED QUALITY IMPROVEMENT TO ACCELERATE PATIENT-CENTERED MEDICAL HOME TRANSFORMATION IN THE VETERANS HEALTH ADMINISTRATION (VHA)

Susan E. Stockdale^{1, 2}; Alicia Bergman¹; Alison B. Hamilton^{3, 2}; Danielle Rose¹; Elizabeth M. Yano⁴; Lisa V. Rubenstein⁵. ¹VA HSR&D, Los Angeles, CA; ²University of California, Los Angeles, CA; ³VA Greater Los Angeles Healthcare System, Los Angeles, CA; ⁴VA Greater Los Angeles Healthcare System, Sepulveda, CA; ⁵RAND and UCLA, Medford, OR. (Control ID #3179187)

BACKGROUND: Transforming primary care toward patient-centered medical home (PCMH) models requires cultural, technical, and clinical innovation. Evidence-Based Quality Improvement (EBQI) engages research evidence, organizational data, and boundary-spanning organizational stakeholders in innovation. Previous studies in the VHA comparing EBQI to non-EBQI sites in a modified stepped-wedge design showed more rapid adoption of

PCMH features and reduced primary care provider burnout in EBQI sites. Little information is available, however, on EBQI implementation and fidelity to its key features. In this study, we assessed fidelity to three key EBQI features over four study years (2010-2014).

METHODS: EBQI for PCMH was rolled out in one Southern California/Nevada VHA region from April 2010-September 2014, and included 9 primary care practices and 7 cross-site, topic-focused workgroups. Key features included: 1) Leadership and front-lines priority setting process for primary care QI; 2) QI learning collaborative for front-line primary care and cross-site QI teams; and, 3) support for the use of data/evidence to inform QI. We reviewed project files to assess fidelity to these key features based on explicit criteria. We used qualitative analysis of 73 interviews conducted in Sept 2013-Feb 2014 and July 2014-January 2015 to assess stakeholder perceptions of EBQI. Participants included multi-level, interprofessional leaders; primary care providers; staff; and researchers.

RESULTS: Data showed high or medium fidelity for participation in the priority setting process, with 72 QI projects submitted by frontline QI teams between 2011 and 2014 and 24 interprofessional regional leaders participating in at least one of four rounds of project proposal review. 26 QI projects were prioritized by leaders; QI teams completed 21 projects and 16 projects resulted in tools/toolkits for spread. Participation in QI collaborative activities varied by site, but all sites attended in-person across-site collaborative learning sessions and bi-weekly telephone calls. Most QI teams showed high or medium fidelity for using data or evidence in their QI projects. Qualitative interviews identified bi-directional communication between leaders and QI teams, project management and data support for QI, and partnership with health services researchers as critical for achieving fidelity to EBQI features.

CONCLUSIONS: These findings suggest that participation in local primary care QI is enhanced by 1) systematically linking multi-level, interprofessional leadership to frontline innovators; 2) across-site communication and learning; and 3) availability of project management and data support. Learning health systems search for effective methods for developing evidence-based innovation and improvement agendas that span organizational boundaries and engage the frontlines. Our data support EBQI as a method for achieving these goals, advancing our understanding of complex QI interventions.

FINANCIAL IMPLICATIONS TO THE VETERANS AFFAIRS HEALTHCARE SYSTEM OF ALLOWING FOR 12-MONTH DISPENSING OF ORAL CONTRACEPTIVE PILLS
Colleen P. Judge-Golden¹; Kenneth J. Smith¹; Maria K. Mor²; Sonya Borrero^{1, 2}. ¹University of Pittsburgh, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #3164458)

BACKGROUND: The Veterans Affairs (VA) Healthcare System stipulates a 3-month maximum dispensing limit for all medications, including oral contraceptive pills (OCPs). However, emerging evidence from other practice settings suggests that 12-month OCP dispensing improves continuation, decreases coverage gaps between medication refills, and reduces unintended pregnancy. We aimed to evaluate financial implications for VA of a 12-month OCP dispensing option, with the goal of informing potential policy change.

METHODS: We developed a decision model from the VA (payer) perspective to estimate incremental costs of allowing the option to receive 12 months of OCPs, compared to 3 months (Figure). Per-woman average and total costs were estimated over a 1-year time horizon. Because a subset of VA-users incur co-pays for OCPs,

base case analyses assumed that 50% opt to receive 12 months. Probabilities of OCP continuation, coverage gaps, pregnancy and pregnancy outcomes were drawn from published data. Costs of OCP provision and pregnancy-related care, and the number of women using OCPs were drawn from VA administrative data. One-way and probabilistic sensitivity analyses were performed to assess model robustness.

RESULTS: The 12-month dispensing option resulted in VA cost savings of \$96.49 per woman per year compared to 3-month dispensing, or \$2,345,575 total saved annually. Cost savings resulted from an absolute reduction of 34 unintended pregnancies per 1,000 women per year with 12-month dispensing, or 827 unintended pregnancies averted annually. Expected cost savings with 12-month dispensing were sensitive to changes in the probability of an OCP coverage gap given 3-month dispensing, probability of pregnancy during coverage gaps, and the proportion of pregnancies paid for by VA. In probabilistic sensitivity analysis simultaneously varying all parameters over plausible ranges, the 12-month strategy was cost saving in 97% of model iterations.

CONCLUSIONS: Adoption of a 12-month OCP dispensing option is expected to produce substantial cost savings for VA while reducing unintended pregnancies experienced by women Veterans served by VA. The proposed policy change would better support women Veterans in meeting their reproductive goals, and is economically feasible for VA.

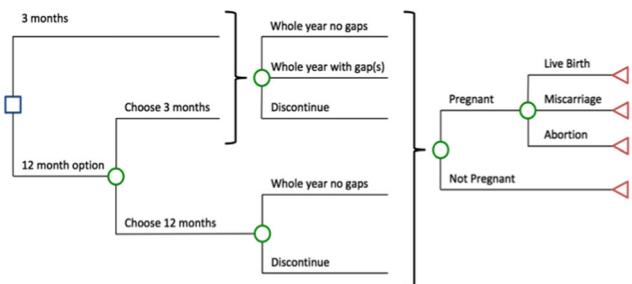

Figure. Decision model schematic

FOOD INSECURITY AND HEPATIC FIBROSIS MEASURED BY TRANSIENT ELASTOGRAPHY AMONG WOMEN WITH AND AT RISK FOR HIV

Ilya Golovat¹; Yifei Ma¹; Sheri D. Weiser¹; Jennifer C. C. Price¹; Mark H. Kuniholm²; Howard Minkoff³; Audrey L. French³; Adaora Adimora⁴; Igbo Ofoekun⁵; Margaret Fischl⁶; Deborah Konkle-Parker⁷; Eric Seaberg⁸; Phyllis C. Tien¹. ¹University of California San Francisco, San Francisco, CA; ²University at Albany, State University of New York, Rensselaer, NY; ³CORE Center/Stroger Hospital of Cook County, Chicago, IL; ⁴University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁵Emory School of Medicine, Atlanta, GA; ⁶Miami Center for AIDS Research, University of Miami Miller School of Medicine, Miami, FL; ⁷University of Mississippi Medical Center, Jackson, MS; ⁸Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ⁹Maimonides Medical Center, Brooklyn, NY. (Control ID #3183408)

BACKGROUND: Non-alcoholic Fatty Liver Disease (NAFLD) will soon be the leading cause of chronic liver disease in people living with HIV. Household food insecurity (FI) may be an upstream determinant of metabolic risk. In a U.S. general population survey, very low food security was associated with increased NAFLD risk. Among women with HIV, FI is highly prevalent (>30%) and has been linked to key risk factors for

NAFLD, including obesity and poor diabetes control. Studies of liver disease in the setting of HIV infection have been limited to the use of indirect serum markers of fibrosis that may be affected by HIV infection itself. We evaluated the relationship of FI with liver fibrosis estimated by transient elastography in a large cohort of women with and at risk for HIV.

METHODS: We conducted a cross-sectional analysis of women with and without HIV from the multicenter Women's Interagency HIV study. Inclusion criteria were age>18 years, no active hepatitis B or C infection, not pregnant, and not reporting heavy alcohol use. FI was estimated using the US Department of Agriculture's Core Food Security Module (18-point scale). Since liver fibrosis may result from the cumulative stress of FI, we defined *persistent* FI as consistently reporting FI+ over an 18-month period (> 2 of previous 3 semi-annual visits); *any* FI (1 of 3 previous visits reporting FI+); and food secure (3 previous visits reporting no FI). Our primary outcome was liver stiffness (LS) measured using vibration-controlled transient elastography at a subsequent visit and analyzed continuously in kiloPascals (kPa). We used multivariable linear regression, adjusting for socio-demographics (age, gender, ethnicity, education, household income), traditional metabolic risk factors (diabetes, body mass index, self-reported menopause status) and HIV status.

RESULTS: 1,042 women (744 HIV-seropositive; 82% African-American) from 9 study sites completed a liver stiffness measurement and food security surveys. 19% reported persistent FI and 15% reported any FI in the past 18 months. Overall, 18% of the population had significant fibrosis (i.e. LS>7.1 kPa; median 5.0 kPa; IQR: 3.9, 6.6) and 52% had BMI >30 kg/m² (median 30.5 kg/m²; IQR 26.0, 35.7). Compared to food-secure women, those reporting persistent FI had 5% lower liver stiffness that did not reach statistical significance (95% CI: -11%, 1%), whereas there was little association of *any* FI with liver stiffness (1%; 95% CI: -6%, 7%). After multivariable adjustment including metabolic factors and HIV status, the relationship between food security and liver stiffness remained unchanged.

CONCLUSIONS: Contrary to expectations, we did not observe an independent association of FI with liver fibrosis among our population of women with or at risk for HIV. Using a highly specific measure for fibrosis, the overall high metabolic burden in this cohort may have masked an appreciable difference in liver stiffness by FI.

FOSTERING PHYSICIAN PRESENCE IN PRIMARY CARE: FINDINGS FROM A HUMAN-CENTERED DESIGN PROJECT AND DELPHI PANEL

Donna M. Zulman^{1, 2}; Marie Haeverfield^{1, 2}; Rachel Schwartz^{1, 2}; Jonathan G. Shaw^{1, 2}; Cati Brown-Johnson^{1, 2}; Dani L. Zions¹; Nadia Safaeinili¹; Aaron A. Tierney^{1, 2}; Meredith Fischer¹; Sonoo Thadaney¹; Steven Asch^{1, 2}; Abraham Verghese¹. ¹Stanford University, Stanford, CA; ²VA Palo Alto Health Care System, Menlo Park, CA. (Control ID #3180119)

BACKGROUND: Modern medicine has produced record levels of physician distress, as clinicians attempt to reconcile time constraints and administrative demands with empathy and caring. While structural changes are undeniably needed, there is evidence that certain physician actions and communication practices can lead to more meaningful and effective patient encounters. We sought to identify evidence-based practices through which physicians can adopt a state of *presence*—a purposeful practice of awareness, focus, and attention with the intent to understand and connect with patients.

METHODS: We derived potential presence practices through a systematic literature review of effective interpersonal interventions (n=77 articles), followed by a human-centered design process that included clinical observations of 29 primary care encounters (at an academic medical center, a VA general medicine clinic, and a Federally Qualified Health Center), qualitative interviews with primary care physicians (n=10) and patients (n=29), and

interviews with non-medical professionals whose jobs involve intense interpersonal interactions (n=30). After synthesizing the evidence, we identified 13 preliminary presence practices. We then conducted a 3-round modified Delphi process with 14 national experts, including researchers, physicians, patients, caregivers, and health system leaders. The experts reviewed and rated the practices on three 9-point Likert scales [range -4 to +4] that reflected the potential impact on patient experience, potential impact on clinician experience, and implementation feasibility. We prioritized practices with median rantings 2 for all three criteria.

RESULTS: Eight practices received high ratings for implementation feasibility and the potential to positively impact patient and clinician experience: 1) Come prepared (review patient information before the encounter to focus and familiarize yourself with the patient you are about to see); 2) Take a moment to focus (incorporate a brief ritual into clinical practice to focus your attention on the impending patient encounter); 3) Position yourself (use positive open body language, e.g., sit down, lean in, orient your body towards the patient); 4) Listen without interrupting (avoid interjecting during a patient's opening description of health issues); 5) Elicit patient priorities and incorporate these priorities into the visit agenda; 6) "Walk in the patient's shoes" (consider a patient's sociocultural and life circumstances); 7) Focus on the positive (acknowledge specific patient efforts in a genuine and positive manner); and 8) Attend to patient emotions (assess and acknowledge patient feelings).

CONCLUSIONS: Through a novel process that combined a systematic literature review with human-centered design and Delphi methodology, we identified simple and concrete practices that facilitate clinician presence and connection with patients, and have the potential to improve patient and physician experience.

FREQUENCY OF INPATIENT DEATHS DUE TO MEDICAL ERROR: A SYSTEMATIC REVIEW AND META-ANALYSIS

Benjamin Rodwin^{1, 2}; Victor P. Bilan^{1, 2}; Naseema B. Merchant^{1, 2}; Catherine G. Steffens²; Lori A. Bastian^{1, 2}; Craig G. Gunderson^{1, 2}. ¹Yale School of Medicine, New Haven, CT; ²VA Connecticut Healthcare System, West Haven, CT. (Control ID #3138948)

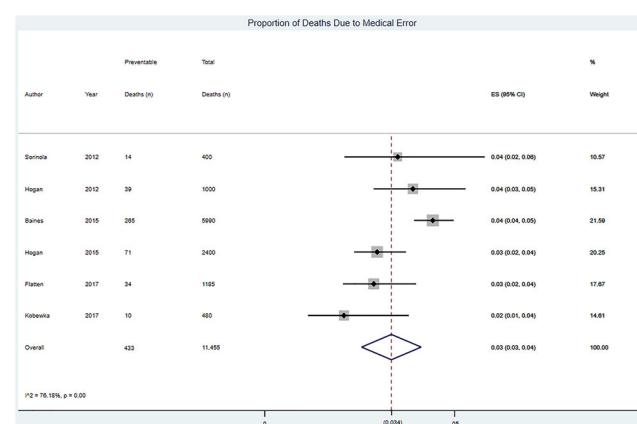

BACKGROUND: Since the Institute of Medicine report *To Err Is Human* in 1999, preventable inpatient deaths in the United States have been estimated as between 44,000 and 98,000 annually. A more recent review concluded that the number of preventable deaths was over 250,000 annually. Because inpatient deaths are believed to be commonly due to medical error, and therefore preventable, mortality rates are used for hospital rankings by the Centers for Medicare and Medicaid services (CMS) and the Veterans Administration. Given the uncertainty in reported rates of preventable mortality, we undertook a systematic review and meta-analysis of studies that directly assess rates of preventable mortality in hospitalized patients.

METHODS: A systematic search was conducted for studies that reported case series of hospitalized patients who died and used physician review to determine the number of deaths due to preventable medical errors. Our search included MEDLINE, EMBASE, Web of Science, and the Cochrane library. Study quality was assessed using the Newcastle-Ottawa Quality Assessment Scale. Mortality rates were pooled using random-effects meta-analysis.

RESULTS: 1,086 studies were screened for inclusion. Six studies including 11,455 deaths met study inclusion criteria. The overall pooled rate of mortality due to preventable error was 3.4% (95% CI 2.7% - 4.2%) (figure 1). Two studies reported rates of preventable mortality limited to patients expected to live longer than three months, which was 0.8% (95% CI 0.3% - 1.9%). In the United States, these estimates equate to approximately

21,450 preventable deaths annually and 5,720 deaths among patients with greater than three-month life expectancy.

CONCLUSIONS: The number of deaths due to medical error is much lower than previously reported. Furthermore, most of these preventable deaths appear to occur in patients with less than three months life expectancy. Because the vast majority of inpatient deaths are not due to medical error, overall hospital mortality rates are unlikely to be valid quality measures. Variation is more likely to reflect differences in patient characteristics and location of patient death. Our results also question the validity of using disease-specific mortality rates for quality measures and reimbursement, as currently done by CMS.

FREQUENTLY HOSPITALIZED PATIENTS' PERCEPTIONS OF FACTORS CONTRIBUTING TO HIGH HOSPITAL USE

Kenzie A. Cameron¹; Margaret Chapman²; Shandu Foster¹; Lyndsey O'Hara¹; Bruce L. Henschen¹; Kevin O'leary¹. ¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Massachusetts General Hospital, Ipswich, MA. (Control ID #3180056)

BACKGROUND: Frequently hospitalized patients pose unique challenges to existing medical and psychosocial support networks offered within the current model of health care delivery. Most studies focus on understanding this "high utilizer" population from the perspective of the clinician or health care system. We sought to obtain patients' perspectives of factors associated with onset and continuation of high hospital use.

METHODS: This qualitative study took place at a large, urban, 894-bed hospital. From December 2016-September 2017, we recruited adult patients admitted to the general medicine services and conducted one-on-one semi structured interviews. Eligible participants had two-unplanned 30-day inpatient hospital readmissions within the prior 12 months, and one or more of the following: 1 readmission in last 6 months, referral from a clinician, or 3 observation visits. Our interview guide sought to explore, from the patients' perspective, what factors contribute to patients becoming and continuing to be high-utilizers of hospital care. Digital audio recordings were transcribed verbatim, de-identified, and analyzed using an iterative inductive team based approach to coding. In our first cycle coding, coders used

descriptive coding and subcoding to generate a preliminary code-book with code definitions. Our second coding cycle utilized pattern coding to identify consistency and associations both within and between transcripts. Participant recruitment, interviews, and analysis of transcripts continued until no new codes emerged and thematic saturation was achieved.

RESULTS: Overall, 26 participants completed interviews; 42.3% were female, 73.1% were non-white, and mean age was 47.0 (sd=15.3). The median number of admissions in past year was 8.5 (interquartile range 6.0 - 11.0). Four main themes emerged. First, major medical problems were universal but the onset of frequent hospital use varied, such that some participants had experienced periods of high hospital use throughout their lifetime, while others experienced high hospital use as an adult. Second, participants perceived fluctuations in their course of illness to be related to psychological, social, and economic factors. Social support was perceived as helpful and participants benefitted when providing social support to others. Third, episodes of illness could range from sudden onset to a gradual onset of symptoms, but generally seemed uncontrollable and often unpredictable to the participant. Fourth, participants strongly desired to avoid hospitalization and typically sought care only after self-management failed.

CONCLUSIONS: Emergent themes pointed to factors that influence patients' onset of high hospital use, fluctuations in their illness over time, and triggers to seek care during an episode of illness. These findings enable patients' perspectives to be incorporated into the design of programs serving similar populations of frequently hospitalized patients.

FROM THE #METOO FRONTLINES: INCOMING INTERNS REPORT A BREADTH OF EXPERIENCES RELATED TO SEXUAL HARASSMENT IN MEDICAL SCHOOL
Emmanuelle B. Yecies^{1, 2}; Melissa McNeil^{3, 2}. ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #3184999)

BACKGROUND: The prevalence of sexual harassment in medicine has recently been in the spotlight, with up to 30% of female physicians reporting sexual harassment in the workplace. There is also increasing recognition that the spectrum of sex discrimination includes microaggressions, the prevalence of which have yet to be elucidated. Medical students are a particularly vulnerable population within medicine as they experience the widest power differentials and their ongoing grades and evaluations deepen the consequences of retaliation to reporting. With the influence of the #MeToo movement, a few medical school deans have seen an increase in reporting, but most schools report stagnant (and low) reporting rates, indicating that sexual harassment may still be under-represented in the current reporting system. We aimed to study the ways in which medical students experienced sexual harassment in medicine.

METHODS: An in-person cross-sectional survey was administered to incoming interns at UPMC about their experience with sexual harassment in medical school. An optional question invited respondents to share experiences of sexual harassment in free-text form. The reports were examined for common themes.

RESULTS: 185 graduates of U.S. medical schools returned the survey, with 42 completing the optional free-text question ("If you are willing and interested in sharing any of your experiences, please use the space below"). Of these, 33 respondents identified

as female, and 9 as male. Analysis of the responses revealed six recurring themes: (1) decision not to report, (2) unsuccessful reporting, (3) disproportionate "scut" work for female students, (4) inappropriate comments and touching, (5) repeat offenders with well-known reputations, and (6) male patients harassing female students. This last theme was particularly attributed to Veterans Administration (VA) patients.

CONCLUSIONS: More female students than male students shared negative experiences. They identified a breadth of experiences attributed to both colleagues/superiors and patients. Most importantly, many students identified the current reporting system as discouraging of reporting. Given the variety of experiences shared by incoming trainees, tackling sexual harassment must evolve from a single broad campaign to targeted approaches for each of these issues. The current reporting system appears to be insufficient and reforms are needed to develop an improved system that encourages and supports trainees to report inappropriate experiences.

FURTHER VALIDATION OF THE CONSUMER HEALTH ACTIVATION INDEX (CHAI) AMONG DIVERSE PRIMARY CARE SETTINGS

Guisselle Wismer¹; Laura M. Curtis¹; Lauren Opsasnich¹; Scott Hur¹; Stacy Bailey¹; Rachel O'Conor¹; Marina Arvanitis¹; Alex Federman²; Ruth Parker⁴; Amisha Wallia³; Michael S. Wolf¹. ¹Northwestern University, Chicago, IL; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³Northwestern Medicine, Chicago, IL; ⁴Emory University, Atlanta, GA. (Control ID #3185042)

BACKGROUND: Although there has been increasing interest in patient activation, few measures are publicly available and suitable for patients with limited health literacy. The Consumer Health Activation Index (CHAI) is a valid, reliable, and easily administered tool that can be used to assess health activation among a diverse adult population, including those with limited health literacy. This study was completed to further validate the CHAI in a more diverse different setting.

METHODS: We used data from two ongoing randomized controlled trials of community dwelling adults. 617 English and Spanish-speaking patients who had been prescribed 5+ medications were recruited in outpatient academic and federally qualified health center practices in New York City, NY and Chicago, IL. Outcomes included health literacy via the Newest Vital Sign assessment (NVS), regimen adherence (ASK-12), depression (PROMIS) and blood pressure. To confirm CHAI associations with health outcomes, we ran correlations between the CHAI and depression, regimen adherence, and blood pressure. We obtained the alpha, Eigen, and factor loadings range.

RESULTS: The mean age of participants was 60 years; 36.5% were men, 73.5% had a high school education or less, and 91.9% had an annual income of less than \$30,000. Nearly half (41.5%) of participants had limited health literacy. The CHAI showed good internal consistency ($\alpha = 0.82$). The ten items included in the CHAI loaded onto a single factor (Eigenvalue: 3.24, 9 of 10 factor loadings ranged 0.45-0.66; one item <0.20). A higher CHAI score was associated with fewer depressive symptoms ($r=-0.34$, $p<0.001$) and greater medication adherence ($r=-0.46$, $p<0.001$). No significant differences were noted by blood pressure ($r=0.04$, $p=0.28$).

CONCLUSIONS: The CHAI tool is a reliable, valid measure of consumer health activation that demonstrated exceptional psychometric performance, although opportunities may exist for further

reducing items. CHAI scores were also associated with patient-reported outcomes, while not being associated with intermediary clinical outcomes. These results suggest the CHAI should still be considered a viable, publicly available alternative to existing activation measures.

GAPS IN INSURANCE COVERAGE AMONG LOW-INCOME ADULTS AFTER THE AFFORDABLE CARE ACT
Anna Goldman^{2, 1}; Benjamin D. Sommers³. ¹Cambridge Health Alliance, Cambridge, MA; ²Havard T.H. Chan School of Public Health, Boston, MA; ³Harvard School of Public Health, Brookline, MA. (Control ID #3185319)

BACKGROUND: Gaps or changes in health insurance coverage, known as "churning," is a common problem in Medicaid and has been shown to have adverse consequences.^{1,2} Little is known about the effect of the Affordable Care Act's (ACA) Medicaid expansion on churning rates. We used a difference-in-differences framework to compare coverage continuity for low-income adults in expansion vs. non-expansion states under the ACA.

METHODS: We analyzed data from the Medical Expenditure Panel Survey on monthly insurance status for the years 2011-2016 (the ACA's Medicaid expansion went into effect in 2014). Our study population (n=14,370) included non-elderly adults ages 19-64 with family incomes under 138% of poverty who reported having Medicaid for at least one month. Our intervention group included adults residing in states that expanded Medicaid prior to December 31, 2015. Our control group included adults in states that did not expand Medicaid prior to the end of our study period. Individuals living in Montana and Louisiana, which expanded Medicaid during in 2016, were excluded. In our primary analysis, we examined changes in churning rates among Medicaid enrollees in expansion vs. non-expansion states before and after the ACA. The annual churning rate was defined as the proportion of Medicaid enrollees who moved from Medicaid coverage to no coverage or non-Medicaid at any point during the year. A second outcome was the proportion of Medicaid enrollees who experienced a coverage gap, defined moving from Medicaid coverage to no coverage. Lastly, to explore the impact of churning on access to care, we analyze the following outcomes in expansion vs. non-expansion states: inability to get necessary care; delays in care; and delays in obtaining prescription drugs.

RESULTS: The annual churning rate among Medicaid enrollees in expansion states was 17.9% prior to the ACA, and it declined by 4.2 percentage points ($p=0.02$) in the post-ACA period compared to non-expansion states. Gaps in coverage were experienced by 14.0% of Medicaid enrollees in expansion states prior to the ACA, and this rate decreased by 4.1 percentage points ($p=0.02$) after Medicaid expansion. Access to care outcomes did not change significantly in association with expansion status in this population of Medicaid-enrolled adults.

CONCLUSIONS: Using a quasi-experimental approach, we found that churning rates and gaps in coverage for low-income adults decreased significantly in states that expanded Medicaid. Measures of access to care did not change significantly between the study groups. Previous research has documented that Medicaid expansion significantly reduced the uninsured rate among low-income adults. Our study makes a novel contribution in showing that some of this effect is due to reduced churning among existing beneficiaries, in addition to new enrollment. Mechanisms for the

reduced churning rates due to Medicaid expansion include the ACA's higher income eligibility, uniform income cutoffs across eligibility groups, and better outreach.

GASPING FOR AIR: MEASURING PATIENT EDUCATION AND ACTIVATION SKILLSETS IN TWO CLINICAL ASSESSMENT CONTEXTS

Jeffrey Wilhite¹; Kathleen Hanley¹; Khemraj Hardowar¹; Harriet Fisher¹; Lisa Altshuler¹; Adina Kalet¹; Colleen C. Gillespie^{1, 2}; Sondra Zabar¹. ¹NYU School of Medicine, New York, NY; ²NYU, New York, NY. (Control ID #3185457)

BACKGROUND: Asthma education should focus on patient self-management support. Objective structured clinical examinations (OSCEs), as measured by standardized patients (SPs), provide a controlled, simulated setting for timed competency assessments while Unannounced Standardized Patients (USPs) measure clinical skills transfer in real world clinical settings. Both enable us to assess skills critical for providing quality care to patients. Learners seeing USPs have added real world stressors such as clinical load. This study describes differences in education and activation skills in two assessment contexts.

METHODS: A cohort of primary care residents (n=20) were assessed during two time points: an OSCE and a USP visit at an urban, safety-net clinic from 2009-2010. Residents consented to use of their de-identified routine educational data for research. The SP and USPs presented with the same case; a female asthmatic patient with limited understanding of illness management and concern over symptom exacerbation. Providers were rated using a behaviorally-anchored checklist upon visit completion. Competency domains assessed included patient education (4 items) and activation (4 items). Within the education domain, items included illness management, while the activation domain items assessed resident communication/ counseling style. Responses were scored as not done or well done. Summary scores (mean % well done) were calculated by domain. OSCE vs USP means were compared using a paired samples t-test.

RESULTS: Residents were more likely to offer an oral steroid as treatment in the OSCE case (50% vs. 35% for USPs), but performed better with USPs on most other items including domain scores. Residents seeing a USP scored significantly higher on five out of eight individual assessment items ($p<.05$) including recommending a spacer, helping a patient understand their condition, making patients feel like they can take control of their own health, helping a patient understand illness management, and having a patient leave feeling confident in finding solutions independently. Inhaler technique was assessed rarely in either setting (OSCE: 15%, USP: 5%). Domain summary scores (% well done) from the OSCE (activation: 12%, education: 31%) were lower than USP scores (activation: 84%, education: 37%), with differences in overall activation scores being significant ($t(19)=-8.905, p<.001$).

CONCLUSIONS: OSCEs are a widely accepted tool for measuring resident competency in a standardized environment but may be focused primarily on knowledge and technical skills. While SPs are trained to be as objective as possible, rater bias might impact scores. USPs may provide more nuanced assessments of communication skills in a setting with reduced time constraints. Next steps include examining attitudes toward OSCEs vs the clinical setting, looking at impact of provider gender, and examining setting-specific issues that promote or hinder high quality care.

GENDER AND ACADEMIC HOSPITALISTS

Carrie A. Herzke¹; Joanna M. Bonsall⁴; Amanda Bertram³; Hsin-Chieh Yeh²; Arielle Apfel³; Joseph Cofrancesco². ¹Johns Hopkins, Baltimore, MD; ²JHUSOM, Baltimore, MD; ³Johns Hopkins University, Baltimore, MD; ⁴Emory University School of Medicine, Atlanta, GA. (Control ID #3180219)

BACKGROUND: Issues of gender inequity in recruitment, retention and advancement of women in academic medicine persist. Within GIM, there are fewer female division directors, first/last authors and presenters at national meetings. Academic Hospital (AH) medicine is a growing field and studies raise a concern about gender equity.

METHODS: A national survey via Qualtrics ® of all leaders of AH programs associated with AAMC. Survey was developed via literature review, discussion/pilot with experts, in collaboration with the Society of Hospital Medicine. Domains included program/faculty information and perceptions about promotion. Gender of the leader was determined via website or telephone. Programs excluded if no identifiable primary teaching hospital or hospitalist program, or not staffed by university-affiliated physicians. Means, standard deviations, medians, and proportions were used to describe data distribution. Chi-square, Fisher's Exact test, and t-test were used in univariate analysis to compare respondents and non-respondents, and to determine if leader and program characteristics were significantly associated with being in the lowest quartile of female faculty. Multivariable logistic regression was used to determine adjusted associations.

RESULTS: 58% response rate (78 of 135); no differences of non-responders in NIH funding, public v. private, geographic region or year established. Reported number of female and male faculty approximately equal. 73% of hospitalist leaders were male; 38% of male leaders were professors, no female leaders were professors. In univariate analysis, there were no gender associated differences regarding importance of scholarship for promotion but programs with the highest quartile of associate and professors had lowest quartile of female faculty. Other predictors of having lowest quartile of female faculty include less NIH funding, single promotion track, more time with learners, fewer total faculty, and fewer faculty ranked instructor. In the multivariable regression model, institutions with lowest quartile of NIH funding were significantly associated with the lowest quartile of female faculty (odds ratio=3.54, p=0.049) after adjusting for covariates. Having lower female faculty was not associated with amount of protected time, GIM versus independent division/department, region, or number of faculty remaining in hospital medicine long-term.

CONCLUSIONS: This study demonstrated gender issues in academic hospital medicine, especially regarding leadership and rank. Though equal gender distribution of faculty with similar plans to remain in AH, leaders are predominately male, no female leaders are professors and programs reporting higher numbers of female faculty were most likely to report lower rates of faculty at the associate and professor rank. As diversity benefits the tripartite mission, and can lead to more diverse role models for learners, faculty and patients, research on methods, initiatives and program that achieve gender equity are needed.

GENDER DIFFERENCES IN AND PATTERNS OF HEALTH-RELATED COMMUNITY RESOURCE NEEDS AMONG ADULT PRIMARY CARE PATIENTS

Jennifer A. Makelarski; Elizabeth L. Tung; Stacy T. Lindau. University of Chicago, Chicago, IL. (Control ID #3185890)

BACKGROUND: As payment models shift from fee-for-service to value-based, health systems are seeking evidence-based strategies for managing population health. The U.S. Centers for Medicare & Medicaid Services is currently assessing an Accountable Health Communities (AHC) model which uses a standardized screener to assess and address, during clinical visits, health-related social needs (HRSNs) including food, housing, rent/utility support, interpersonal safety, and social support. The purpose of this study is to examine gender differences in acceptability of the AHC HRSNs screener and patterns of HRSNs among adult primary care patients.

METHODS: Participants were enrolled in the primary care waiting room of an urban, academic medical center 09/2017-07/2018. Study participants included adults ages 18 and older who spoke English or Spanish, were seeking primary care and were randomized to complete the AHC HRSNs screener and related acceptability questions via a tablet. Sociodemographic and health care characteristics, acceptability of the AHC screener, and self-reported HRSNs were described by gender and differences were examined using Student's t-test (continuous variables) or Chi-squared statistics (categorical variables).

RESULTS: Study participants were predominantly non-Hispanic black (65.9%) and aged 35-64 years old (50.5%). There were no significant differences in sociodemographic characteristics between men and women. The majority of women and men reported excellent, very good or good health (82.4% and 64.3%, respectively, p-value=0.06). Acceptability of the AHC screener was high and similar among gender groups. Only a third of all participants had previously been asked about at least 1 HRSNs during a clinical visit in the last 12 months. Nearly two-thirds (63.4%) of men and 44.6 of women reported at least 1 HRSN (p-value, 0.10). Men were significantly more likely than women to report that they would like assistance with 1 social need (39.3 versus 16.4, p-value 0.02). The most common needs were food (28.8 and 40.7, women and men) and housing (28.4 and 42.9, women and men).

CONCLUSIONS: Acceptability of the AHC HRSNs screener and rates of HRSNs are high among men and women. As screening is adopted into clinical practice, low-intensity, scalable solutions to address HRSNs are needed. Men may be more receptive to assistance.

GENERAL PRACTITIONER PERCEIVED WORKLOAD OF PATIENT CHARACTERISTICS

Justin A. Charles¹; Peder Ahnfeldt-Mollerup²; Jens Søndergaard²; Julia Logan¹; Troels Kristensen². ¹Stony Brook University School of Medicine, Stony Brook, NY; ²University of Southern Denmark, Odense, Denmark. (Control ID #3184696)

BACKGROUND: It is well known that patients with certain sociodemographic characteristics provide additional challenges to patient care and add to general practitioner (GP) workload. However, updated measurements of perceived workload in general practice are lacking. Understanding the contribution of different sociodemographic patient types to GP perceived workload may inform planning and resource allocation in general practice. This study aims to measure perceived workload from patients with different sociodemographic characteristics in general practice, and to reduce patient characteristics into underlying constructs and global, rounded measures of perceived workload.

METHODS: A web-based survey was distributed to a random, stratified sample of 1,196 Danish GPs. A part of it contained

questions that measure perceived workload of 11 sociodemographic patient characteristics using a 0-9 Likert scale. Eight of the sociodemographic characteristics were adapted from the Care Need Index (CNI). Three new patient characteristics were added that are relevant to workload in the context of Danish General Practice: early pension, public transfer payment; outside the labor force in job center courses. Exploratory Factor Analysis (EFA) was conducted using principal-component factors method. Additionally, we created an overall perceived workload indicator, weighted by individual patient types.

RESULTS: GPs perceived foreign-born patients to contribute the most (6.82 out of 9) and children under 5 to contribute the least (3.59 out of 9) to their perceived workload. Male GPs perceived a higher workload than female GPs. Factor analysis revealed two stable underlying factors, entitled "Economically Disadvantaged" and "Difficult Communication". Weighted overall perceived workload was 5.49 (out of 9).

CONCLUSIONS: There is considerable variation in how different sociodemographic patient characteristics contribute to perceived GP workload. The suggested measures of overall perceived workload and underlying constructs of perceived workload may simplify how perceived workload is measured and be used to inform the organization of primary care delivery.

GEOGRAPHIC PREVALENCE OF ALCOHOL AND BENZODIAZEPINE CO-INVOLVEMENT IN OPIOID OVERDOSE DEATHS, 2015-2017

Marco Tori¹; Timothy S. Naimi¹; Marc Larochele². ¹Boston Medical Center, Boston, MA; ²Boston University School of Medicine and Boston Medical Center, Boston, MA. (Control ID #3181622)

BACKGROUND: 1. Compare rates of alcohol and benzodiazepine co-involvement in opioid overdose deaths (OOD) among US states and regions. 2. Describe differences in alcohol or benzodiazepine involvement in prescribed and illicit opioid overdose deaths. From 2015-2017 illicit opioids, mainly heroin and illicitly manufactured fentanyl, were responsible for a majority of OOD in the United States, while prescribed opioids were responsible for a minority. Sedating substances like alcohol and benzodiazepines can compound the respiratory depressant effect of all opioids. Polysubstance use is common among OOD and possibly contributes to excess mortality. The prevalence of alcohol and benzodiazepine co-involvement in OOD is not well described at the national or state level.

METHODS: Data from CDC WONDER Multiple-Cause-of-Death files for poisonings involving opioids as an underlying cause of death from 2015-2017 were used to calculate the prevalence of co-intoxication with benzodiazepines and alcohol, among opioid subtypes with respective ICD-10 codes.

RESULTS: For all OOD, state ranges of alcohol and benzodiazepine co-involvement were 7.1%-28.6% and 5.2%-44.6%, respectively. Ranges for alcohol co-involvement in illicit OOD were 8.3%-31.0% and 6.8%-27.2% in prescribed opioids. Ranges for benzodiazepine co-involvement in illicit OOD were 3.8%-38.4% and 10.2%-54.7% in prescribed opioids. There is no correlation (Pearson co-efficient $r=0.075$) between benzodiazepine and alcohol co-involvement in all OOD by state. In 45 states with sufficient data, 35 had higher alcohol co-involvement in illicit OOD, and all states had higher rates of benzodiazepine co-involvement in prescribed OOD.

CONCLUSIONS: Involvement of alcohol and benzodiazepines in OOD varies widely among states and opioid type but affects a large percentage of deaths. Alcohol co-involvement is more common in illicit OOD than benzodiazepines in prescribed OOD. There is no relationship between state benzodiazepine and alcohol co-involvement in OOD.

GET S-M-A-R-T! TEACHING STUDENTS GERIATRIC HEALTH-RELATED GOAL SETTING

Vivianne Oyefusi¹; Paula Leslie²; Rachel Jantea³; Pamela E. Toto⁴; Rollin M. Wright¹. ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA; ³University of Pittsburgh Medical Center, Pittsburgh, PA; ⁴University of Pittsburgh School of Health and Rehabilitation Sciences, Pittsburgh, PA. (Control ID #3185838)

BACKGROUND: Goal-setting, particularly in geriatrics and primary care, is essential to person-centered care. It is linked to improved outcomes, quality of life and health behavior change. While integral to training in some health professions, we suspected third year medical students (MS3) had not yet learned how to develop health-related goals. There is little published data on how skilled clinicians are at eliciting goals from patients despite the acknowledged importance. We piloted a tool to teach medical and other health sciences students how to develop health-related Specific-Measurable-Assignable-Realistic-Time-based (SMART) goals with community-dwelling older adults.

METHODS: Clinical students (including all MS3s) enrolled in an interprofessional geriatrics course sponsored by the University of Pittsburgh School of Medicine participated in a geriatric assessment skills fair. Each student attended 12 out of 18 possible skills stations, spending 12 minutes at each station and collecting skills cards to prepare them to do geriatric assessments at 9 community-based health fairs in western Pennsylvania in October 2018. All students were required 1) to attend the SMART goals station where they practiced developing health-related SMART goals, and 2) to apply this new skill and elicit at least 1 SMART goal from each senior health fair participant, writing them on health assessment forms. We graded the goals according to the number of S-M-A-R-T elements represented. Without clinical information available, goals were presumed to be Realistic for all the senior participants. Goal statements were independently graded as meeting 0 to 4 elements by the skills station instructor (PL) and the course director (RW) for comparison.

RESULTS: 200 students from 9 health professions schools worked in teams of 2-3 to complete health assessments on 209 geriatric health fair participants, eliciting a total of 112 SMART goals. 49% of elicited goals had 3+ SMART elements. 83 goals were assignable, 71 were measurable, 55 were specific, and 22 were time-based. "Memory problems, blood sugar control, and fall risk" and "call ear doctor to make hearing aid appointment in the next week" were examples of poorly-written (0 elements) and well-written (all 4 elements) goals, respectively.

CONCLUSIONS: We designed a tool that successfully taught health sciences students to engage older people in person-centered, health-related goal-setting, a necessary skill for future careers in an environment that emphasizes high-value health care delivery. "Specific" and "time-based" appeared to be the most challenging of the SMART elements. We will use these findings to refine this education tool further.

GOT CHILDCARE? THE RELATIONSHIP BETWEEN INSTITUTION-BASED CHILDCARE AND EMPLOYEE WELLBEING

Rachel Apple¹; Lauren Samuels²; Christianne Roumie¹. ¹Vanderbilt, Nashville, TN; ²Vanderbilt University, Nashville, TN. (Control ID #3183504)

BACKGROUND: For most parents, securing reliable and safe childcare ranks high on the list of parental priorities. Among health care professionals, there is increasing interest in wellness initiatives to combat growing rates of burnout. Despite the crucial role which finding and securing childcare plays in many parents' lives, few studies have examined the relationship between childcare and wellbeing at the level of a medical institution. The purpose of this study was to evaluate the relationship between utilization of institution-based childcare and employee wellbeing at a large, academic medical center.

METHODS: We conducted a cross-sectional analysis of data obtained from an online survey. Study participants were VUMC employees with children in a Vanderbilt-affiliated childcare center (institution-based childcare) or on the waitlist for Vanderbilt-affiliated childcare (non-institution-based childcare).

RESULTS: 558 respondents were predominantly female (78.0%) and represented a fairly equal distribution between clinical and non-clinical job roles. The majority of respondents (58.8%) reported having 1 child under the age of 6 years in childcare. There was a statistically significant difference in overall stress, with individuals having institution-based childcare reporting less overall stress, as well as less stress specifically related to finances, childcare, and personal health. There was no statistically significant difference between exposure groups related to job, relationship with significant other, or parental responsibilities.

CONCLUSIONS: This study demonstrated an association between childcare provision type and stress after adjusting for demographic factors and potential confounders such as job type, hours per week in childcare, and percent of income spent on childcare. These findings highlight the centrality of childcare to employees' wellbeing and ability to be productive in their jobs. Greater attention to the impact of parenthood on employee stress and wellbeing is warranted at an institutional level.

GRADUATE MEDICAL TRAINEE (GME) INVOLVEMENT IN HOSPITAL MEDICATION SHORTAGE MANAGEMENT

Andrew Hantel¹; Ashley Egan²; Trinh Nguyen²; Erin DeMartino²; Fay Hlubocky¹; Mark Siegler¹; Christopher Daugherty¹. ¹The University of Chicago, Chicago, IL; ²Mayo Clinic, Rochester, MN. (Control ID #3185894)

BACKGROUND: Hospital medication shortages in the United States (US) are associated with decreased patient quality and quantity of life. We recently conducted a national survey to investigate shortage management practices of US hospitals, which revealed widespread shortages of common medications and heterogeneous management and rationing practices. GMEs frequently manage inpatients with varying levels of supervision; internal medicine (IM) and anesthesia residents frequently utilize medications with known shortages to manage patients. Therefore, to understand the involvement of GMEs in shortage management, we conducted a survey of these residents at the University of Chicago Hospital (UCH).

METHODS: A 17-item survey was created to evaluate shortage management. Subjects included trainees at least one year into their program. Items were piloted for clarity and relevance. The survey was performed in person

between 11/4/2018-1/12/2019. 2 tests were used to compare response differences by post-graduate year (PGY) and program. Subjects that responded to at least one question were included in the analysis. The UCH IRB approved the study.

RESULTS: A total of 123 GMEs were eligible; 85 completed the survey (response rate 69.1%). Question completion was 100%. 96.5% reported experience in managing shortages. Of these GMEs, 90.6%, 88.4%, and 75.2% reported managing shortages, using alternatives, and that shortages made clinically relevant differences, respectively, on an at least weekly basis. 47.1% reported that equivalent alternatives were available "half of the time" or less. When shortages occurred, 70.5% of GMEs reported discussing management with their attending "some of the time" or less; when asked to consider only clinically relevant shortages (CRS), this became 53.1%. PGY2 residents and IM residents were more likely to discuss CRS frequently with their attending ($\chi^2=21.3$ and 17.2, $P=0.05$ and 0.01). 49.1% reported discussing CRS with patients "some of the time" or less frequently. IM residents were more likely to discuss CRS frequently with their patients ($\chi^2=26.2$, $P<0.01$). 13%, 8.2%, and 78.8% responded that shortages should be disclosed to patients always, never, or only when clinically relevant, respectively. Of those who preferred to disclose based on relevance, 45.9% would only disclose if shortages resulted in a moderate or major difference in efficacy or toxicity. 14.1% reported receiving shortage training and 91.8% reported that they would want training.

CONCLUSIONS: GMEs frequently manage clinically relevant shortages with little training and variable communication to their supervising physicians or to patients. Less experienced GMEs and IM GMEs are more likely to discuss management with their attendings and IM residents are more likely to discuss management with their patients, as compared to anesthesia GMEs. Further study and education of GMEs is warranted; therefore this survey is currently being performed with UCH emergency medicine GMEs and parallel programs at the Mayo Clinic.

GREAT EXPECTATIONS: A SURVEY OF HOSPITAL PORTAL INFORMATION FOR PATIENTS

Joy L. Lee^{1, 2}; Claire E. Williams²; Sean Baird²; Marianne S. Matthias^{3, 2}; Michael Weiner^{4, 2}. ¹Indiana University School of Medicine, Indianapolis, IN; ²Regenstrief Institute, Inc., Indianapolis, IN; ³Roudebush VAMC, Indianapolis, IN; ⁴Indiana University, Indianapolis, IN. (Control ID #3149443)

BACKGROUND: Adequate access to health care, providers, and information, is a problem for many patients. Patient portals present an opportunity to expand patients' access to care, providers, and information online, most notably through access to electronic medical records and secure messaging. Yet clinicians have expressed concern about patients' "misuse" and "misunderstanding" of portals, especially secure messaging. It is not clear if and what expectations of portal use are communicated to patients. This study sought to identify what hospitals communicate to patients about portal use, to describe the information available to patients, and to assess ease in accessing this information.

METHODS: We randomly sampled 200 acute-care hospitals from the Centers for Medicare & Medicaid Services Hospital Compare dataset, and searched the web to collect publicly available information about each hospital's patient portal. The web search was followed up with phone calls to the hospitals (up to 3 attempts each) to request any additional patient-directed materials (e.g., pamphlets) not included in the web search. Ease of access was defined as the number of mouse clicks from the hospital's main webpage needed to access the portals. A mixed-methods approach was used to evaluate and describe the data.

RESULTS: Although 197 (99%) of the 200 hospitals sampled reported meeting Meaningful Use standards, portal information could only be found for 178 (89%) hospitals. Regarding ease of access, 74% of portals were accessible from the hospital homepage within 3 clicks; 48% offered portals in a language other than English. 108 (61%) portals offered secure messaging, and all of these provided a disclaimer that messaging should not be used for emergencies; 23 hospitals (20%) posted the disclaimer in the terms and conditions. 33% of hospitals with secure messaging provided no additional guidance about messaging. Content analysis of hospital pamphlets revealed a focus on logistical information, portal features, and parameters of use. Logistical information (e.g., how to create an account) was the most thorough and most prevalent. Few hospitals provided guidance on expected behaviors or defined misuse beyond using secure messaging for urgent situations.

CONCLUSIONS: There is a discrepancy between providers' expectations of patients and the information available to patients regarding portal use. Although most hospitals have a patient portal, many fail to set expectations for its use, especially regarding secure messaging. Instead, educational materials largely focused on how to access the portals. To improve patient engagement and for the full benefits of patient portals to be realized while minimizing misuse, hospitals and clinicians need to provide more information and set clearer guidelines for patients.

GROUP VISITS FOR ADVANCE CARE PLANNING FOR PATIENTS WITH HEART FAILURE

Julia Bandini¹; Alexis Coulorides Kogan⁴; Jessica Phillips¹; Bonnie Olsen⁴; Rebecca L. Sudore²; David Bekelman³; Sangeeta Ahluwalia¹.

¹RAND Corporation, Santa Monica, CA; ²University of California, San Francisco, San Francisco, CA; ³University of Colorado, Denver, CO; ⁴Keck School of Medicine, University of Southern California, Los Angeles, CA. (Control ID #3178411)

BACKGROUND: Background: Advance care planning (ACP) is an emotionally and cognitively challenging task, as patients are asked to consider their healthcare preferences in advance of their anticipated decline. We know little about how to encourage patients to engage in this intensive and time-consuming process in healthcare settings, in an efficient and effective manner. Group visits have potential to help patients identify their healthcare values and engage in ACP in a resource-efficient manner. They provide a forum for social learning and social support to empower patients to overcome common barriers to ACP and provide economies of scale that can address provider and system barriers to ACP. Disease-specific group visits may provide common ground for patients to begin thinking about their treatment options and prepare them for future 1-on-1 discussions with their treating provider. We sought to understand whether a disease-focused group visit for ACP is a valuable, acceptable and feasible approach to ACP, including participant preferences for content, learning tools, group composition, and facilitation.

METHODS: Feasibility trial of five 90-minute group visits and 2 follow-up group visits, led by a geriatric psychologist, with 16 patients with heart failure (HF) and 11 caregivers (n=27). Participants completed pre- and post-visit surveys including Likert-scale items on feasibility and acceptability and a 1-on-1 post-visit telephone interview to assess perceived value. Structured observations during the group visits further assessed process and feasibility.

RESULTS: Data from post-visit surveys indicated participants felt comfortable discussing ACP in a group, understood the information covered/ felt it was the right amount, and were able to identify and clarify their

healthcare values. All participants noted they would recommend the group visit to family/friends. Of the 27 group visit participants, 20 (81%) attended a second follow-up group visit covering additional ACP topics. Interview and observation data identified four key themes: participants leveraged others' experiences to identify and clarify preferences and potential choices; participants found value in mixed patient-caregiver groups for understanding alternative perspectives; the disease-focused nature of the visit and peer and social support aspect of the group provided participants with a safe space to share difficult experiences and explore their healthcare preferences and values; and the group visit motivated subsequent ACP steps such as completing an advance directive or sharing preferences with a provider or family member.

CONCLUSIONS: Disease-focused group visits could be an efficient health system intervention for engaging patients and caregivers in the otherwise time- and resource-intensive task of ACP. Policymakers should continue to explore ways to financially support the use of ACP group visits. A second phase of this study is underway to assess group visit effectiveness.

GROWING INEQUALITY IN HEALTH EXPENDITURES FOR REPRODUCTIVE AGE WOMEN: THE INVERSE CARE LAW REVISITED

Samuel L. Dickman¹; Stephanie Woolhandler²; David Himmelstein³.

¹University of California, San Francisco, Oakland, CA; ²Cambridge Hospital, New York, NY; ³City University of New York at Hunter College, New York, NY. (Control ID #3181614)

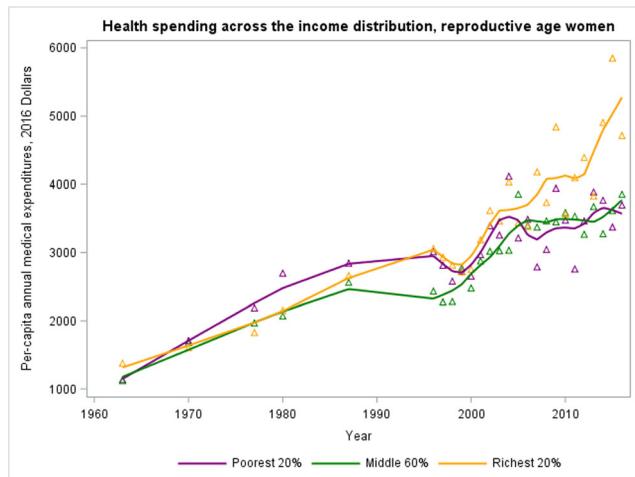

BACKGROUND: Women of reproductive age (15-49 years) have lower incomes and greater healthcare needs than their male peers and may be especially vulnerable to policies that impose cost-sharing (e.g. copayments, deductibles). Death rates for such women have stalled recently, and maternal mortality has risen, raising concern about unmet healthcare needs.

METHODS: We analyzed population-wide healthcare utilization by compiling 801,622 person-years of data from 26 nationally representative surveys over 54 years: the 1963 and 1970 Surveys of Health Services Utilization and Expenditures; the 1977 and 1980 National Medical Care Utilization and Expenditure Surveys; the 1987 National Medical Expenditure Survey; and the 1996-2016 Medical Expenditure Panel Surveys. We tabulated all spending on health services, including out-of-pocket and insurance payments. We assessed income, self-reported health status, and inflation-adjusted spending decomposed into price and volume effects.

RESULTS: Health expenditures for reproductive-age women grew 335% between 1963 and 2016, from \$1,182 to \$3,966 in 2016 dollars. Expenditures for the wealthiest 20% of women accounted for most of the increase since 2000. The growing expenditure gap since 2001 was largely attributable to price increases, which rose 18% faster for high income than low income women. Outpatient visit rates also diverged; wealthy women had 1.2 more visits than poorer women in 1996, a gap that rose to 1.8 visits (95% CI 1.3-2.3) by 2016, despite persistent disparities in health status by income. Twenty-seven percent of poorer women in fair/poor health had total expenditures of less than \$500, an indicator of inadequate access to care, vs. 5.6% of affluent ones ($p<0.05$). ED visit rates were low overall, but higher for poorer than wealthier women: 0.30 vs. 0.13 per capita.

CONCLUSIONS: Medical expenditures and outpatient visits for reproductive age women have become increasingly concentrated among the affluent, a reallocation of health resources away from those with the

highest medical need. Rising cost-sharing may discourage poorer women from seeking care, while diverging fees (i.e. prices) may discourage providers from serving them, to the detriment of population health.

GUIDELINE-CONCORDANT CHRONIC OPIOID PRESCRIBING: DISCREPANCIES BETWEEN KNOWLEDGE, ATTITUDES AND CURRENT PRACTICE IN AN ACADEMIC PHYSICIAN PRACTICE

Mim Ari; Rebecca Chohlas-Wood; Neda Laiteerapong; Lisa M. Vinci; George Weyer. University of Chicago, Chicago, IL. (Control ID #3186298)

BACKGROUND: Many Americans with chronic pain are prescribed chronic opioid therapy, which may improve patient quality of life and pain, but is associated with significant risk, namely opioid misuse, overdose and opioid-related death. In 2016, the CDC published its Guideline for Prescribing Opioids for Chronic Pain to help PCPs prescribe chronic opioids in a safe and effective way. In order to ensure that guidelines are distilled into clinical practice, it is essential to understand the current state of practice. The purpose of this study was to evaluate knowledge, attitudes and beliefs, and practice patterns of physicians in an academic primary care practice with regards to chronic opioid prescribing, in order to assess the need for quality improvement.

METHODS: Thirty-seven general IM physicians at a single academic medical center anonymously completed a survey in 2017 (95% response rate). Physicians were surveyed about knowledge, attitudes and beliefs, and current practice patterns of key aspects of the CDC Guideline. A general sense of "regard" (biases, emotions, and expectations) for patients with chronic pain on long-term opioid therapy was also assessed using the Medical Condition Regard Scale. Data and descriptive analyses was compiled using REDCap software.

RESULTS: While 51% of physicians were aware of the key elements of the patient-provider agreement, and 75% believe them to be very useful, 70% never or rarely used them. Seventy percent of physicians knew how to access the PMP and 76% found the information helpful, however, only 8% checked PMP prior to initiating opioids. Sixty-five percent never performed urine drug screening; knowledge of how to interpret urine drug screening and beliefs of its usefulness were more varied. While most physicians (57%) thought prescribing naloxone was very important, 73% of physicians had never prescribed it. Only 38% of physicians felt that working with patients with chronic pain on long-term opioid therapy was satisfying and 57% found these patients particularly difficult.

CONCLUSIONS: Our data indicate fairly high levels of knowledge and perceived usefulness of key CDC guideline recommendations. However, application of these guidelines was inconsistent. While the opioid

epidemic has received significant publicity, formal education on chronic opioid therapy and support to implement the new guidelines has lagged behind. To tackle this complex issue and increase guideline adherence, a combination of policy changes, health system changes, and physician-level interventions is likely needed. In response to our findings, we have created a clinical practice guideline, a standardized patient-provider agreement, standardized documentation tools for the EHR, and didactic education. Future directions include resurveying physicians and assessing changes in practice using EHR data.

HEALTH IT FOR HEALTH EQUITY: DEVELOPING A CHECKLIST TO IMPROVE THE QUALITY OF EMR DATA COLLECTED TO INFORM HEALTH DISPARITIES INTERVENTIONS

S. M. Ogunwole. Johns Hopkins University School of Medicine, San Antonio, TX; UT Health San Antonio, San Antonio, TX. (Control ID #3176435)

BACKGROUND: The electronic medical record (EMR) is a powerful patient data collection tool that can help organizations identify and monitor disparities in healthcare and health outcomes. This collection of data is often the first and most critical step needed to address health equity within clinical environments. Despite this, many organizations do not leverage their EMR to collect data that can inform and help prioritize interventions that reduce health disparities and improve health equity. We set out to develop a checklist that could identify items needed to ensure quality data capture from the EMR—a critical step for health disparities data collection.

METHODS: Following the World Health Organization (WHO) approach to developing surgical checklists; we assembled evidence on possible areas of improvement, drafted checklist items, solicited an expert review of the draft checklist, validated the checklist using patient and stakeholder feedback, and piloted the checklist at a clinical site. We found traditional quality improvement tools such as creation of a process map detailing the patient intake process, observation of the patient and intake staff interactions and creation of an Ishikawa diagram to identify implementation barriers to be most useful in assessing fulfillment of the checklist items and generating ideas for change based on identified deficits.

RESULTS: We established three domains of requirements for adequate EMR data capture. 1) standardization 2) inclusion of relevant 'metrics that matter'(i.e., social determinants of health) and 3) requirement to report and act on health disparities data. In addition, there were several tasks identified within each domain, leading to a final comprehensive "*EMR equity checklist*" composed of 21 items (see figure 1). On evaluation, we found that only 10/21 checklist items were met. The information from our quality improvement assessment in combination with clearly defined deficits from our checklist allowed generation of specific interventions (ex: intake staff education, EMR changes, and the creation of a Health Equity Taskforce) to address the identified checklist items that were not fulfilled.

CONCLUSIONS: An EMR equity checklist in conjunction with quality improvement tools, created a systematic framework to evaluate and improve the collection of data relevant to health disparities.

In order for Health Information Technology to function at a level that can inform our leadership about health disparities, the following elements have to be met:

Standardization of Data collection
 Data must be reported by patient
 Collected in a culturally sensitive manner
 Complete
 Accurate

Requirement to report and act on health disparities data
 Stratification of data to evaluate the presence of health disparities
 Mechanism to report findings to leadership and create action plans that address the identified disparities

Inclusion of 'metrics that matter'
(Social determinants of health systematically captured)
 Primary language
 Race/Ethnicity
 Health Literacy
 Education level (surrogate for SES)
 Employment
 Financial resource strain
 Stress
 Depression
 Physical activity
 Tobacco use and exposure
 Ethical status
 Abuse of other substances
 Social connections and social isolation
 Exposure to violence: intimate partner violence
 Neighborhood and community compositional characteristics

EMR EQUITY CHECKLIST

HEALTH LITERACY AND SOCIODEMOGRAPHICS ARE MORE IMPORTANT THAN PRIOR EXPERIENCE FOR ADVANCE CARE PLANNING KNOWLEDGE AMONG OLDER ADULTS

Sarah Nouri¹; Deborah E. Barnes²; Aiesha Volow³; Ryan D. McMahan³; Margot Kushel¹; Chengshi Jin⁴; W. John Boscardin³; Rebecca L. Sudore³. ¹University of California, San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA; ³University of California, San Francisco; San Francisco Veterans Affairs Medical Center, San Francisco, CA; ⁴University of California San Francisco, San Francisco, CA. (Control ID #3184653)

BACKGROUND: Engagement in advance care planning (ACP) is low among vulnerable populations, and limited knowledge about ACP has been suggested as a possible modifiable barrier. We aimed to determine the factors associated with ACP knowledge, including prior ACP engagement, health literacy, and sociodemographic factors. We hypothesized that prior ACP engagement would be associated with higher ACP knowledge, and limited health literacy would be associated with lower ACP knowledge.

METHODS: We used cross-sectional baseline data from two randomized controlled trials that enrolled 1400 English- and Spanish-speaking primary care patients aged 55 years with 2 chronic medical conditions from a Veterans Affairs and public hospital system in San Francisco. We assessed ACP knowledge, the outcome variable, with validated multiple-choice questions on a 0-7-point scale. We defined prior ACP engagement as documented legal forms and/or goals of care discussions in the medical record. Sociodemographic measures included age, gender, health literacy (validated s-TOFHLA scores dichotomized into limited vs adequate literacy), preferred language (English vs Spanish), education (vs > high school), race/ethnicity, health status (5-pt Likert scale), finances (limited vs adequate), and social support (11-item validated survey, scores 11 to 55). We used Kruskall-Wallis tests and linear regression analysis to examine associations of prior engagement in ACP and sociodemographic factors with ACP knowledge.

RESULTS: Participants were 65 (± 10) years old; 48% were women, 34% had limited health literacy, 32% were Spanish-speaking, 47% had high school education, 70% were non-white, 45% had fair-to-poor health, and 21% had limited finances. In unadjusted analyses, ACP knowledge scores were higher for those with vs without prior ACP engagement (5.1 (SD 1.8) vs 4.8 (SD 2.0), $p=0.02$). In multivariate analyses adjusted for sociodemographic variables associated with ACP knowledge (gender, health literacy, preferred language, education, race, health status, finances, and social support), prior ACP engagement was no longer associated with knowledge ($p=0.8$). Instead, limited health literacy was associated with 1.0-point lower knowledge scores (4.7 vs 5.7, $p<0.001$), Spanish language and education high school were associated with 0.6-point lower scores (5.1 vs 5.7, $p<0.001$ for each), and non-white race was associated with 0.4-point lower scores (5.3 vs 5.7, $p<0.001$). Higher social support was also independently associated with higher ACP knowledge scores (0.12 knowledge points per 1 social support point, $p=0.004$).

CONCLUSIONS: Health literacy and sociodemographics are more important predictors of ACP knowledge than prior engagement in ACP. This study suggests that providing easy-to-understand, culturally appropriate ACP materials is paramount for vulnerable populations and should be re-offered even if patients have previously engaged in ACP.

HEALTH LITERACY PHENOTYPES: COGNITIVE VS. NON-COGNITIVE LOW HEALTH LITERACY AND IMPACTS ON HEALTH STATUS

Laura M. Curtis¹; Stacy Bailey¹; Mary J. Kwasny¹; Rachel O'Conor¹; Julia Yoshino Benavente¹; Michael Paasche-Orlow³; Alex Federman²; Michael S. Wolf¹. ¹Northwestern University, Chicago, IL; ²Icahn School of

Medicine at Mount Sinai, New York, NY; ³Boston Medical Center, Boston, MA. (Control ID #3185415)

BACKGROUND: The influence of health literacy (HL) on personal health is well-established, and there have been consistent calls to action for health care systems to respond. The underlying HL construct reflects a variety of cognitive and psychosocial factors, but existing HL measures merely identify those with higher vs. lower skills. Understanding the underlying nature of the barrier(s) causing lower HL (e.g. cognitive impairment, limited healthcare knowledge/experience) could better inform healthcare system responses. We sought to investigate the prevalence of two such 'phenotypes' of low HL, cognitive vs. non-cognitive, and evaluate their associations with physical health.

METHODS: 900 adults between the ages of 55 and 74 receiving care at either an academic general internal medicine clinic or 1 of 5 federally qualified health centers in Chicago, IL were recruited for an ongoing study. Structured interviews were conducted that included three HL measures (REALM, TOFHLA, NVS) as well as a detailed psychosocial and neuropsychological battery that allowed for the determination of a cognitive impairment. In addition, participants completed the PROMIS Physical Functioning Short Form. The prevalence of low HL was calculated per test among all subjects, then stratified by those with and without a cognitive impairment to define the 'cognitive' and 'non-cognitive' phenotypes, respectively. Physical functioning t-scores corrected for the general population were then compared across HL levels, overall and stratified by these two health literacy phenotypes.

RESULTS: Among 877 participants with cognitive data, 201(23%) were cognitively impaired and rates of low HL by REALM, TOFHLA, and NVS were 10%, 14%, and 32% respectively. The prevalence of low HL varied by cognitive impairment status (cognitive phenotype: 66% vs. non-cognitive phenotype: 22%; $p<0.001$ (by NVS)). Similar trends were noted by REALM and TOFHLA measures. Differences in mean (SD) physical function scores were noted across HL levels among all participants (NVS: low 44.1(9.1), marginal 47.1(8.8), adequate 50.1(8.1), $p<0.001$; TOFHLA: low 42.4(8.4), marginal 45.4(9.1), adequate 49.2(8.5), $p<0.001$; REALM: low 42.6(9.1), marginal 45.5(9.2), adequate 48.7 (8.6), $p<0.001$). Significant, gradient trends with better physical health increasing with greater HL skills persisted in both phenotypes (NVS: (cognitive): low 42.4(9.3), marginal 46.8(10.0), and adequate 46.8(8.2), $p=0.01$; (non-cognitive): low 45.6(8.7), marginal 47.1(8.5), and adequate 50.3(8.1), $p<0.001$).

CONCLUSIONS: This initial investigation into the possibility of multiple HL phenotypes suggests that even among cognitively 'normal' participants, limited HL can negatively impact physical health, albeit scores were still significantly higher than those with a cognitive impairment. This may directly inform the design of HL interventions, recognizing that different approaches will be needed to remediate different phenotypes of HL.

HEALTH SYSTEM PARTICIPATION IN ALTERNATIVE PAYMENT MODELS AND INSURANCE PRODUCTS

Laura Kimmy¹; Rachel Machta¹; David J. Jones¹; Michael Furukawa²; Eugene C. Rich³. ¹Mathematica Policy Research, Durham, NC; ²Agency for Healthcare Research and Quality, Rockville, MD; ³Mathematica Policy Research, Silver Spring, MD. (Control ID #3186475)

BACKGROUND: In the past decade, consolidation of hospitals and physicians into local or regional health systems has increased in the U.S. Researchers, policymakers, health system leaders and others may be interested in studying health system characteristics and their relationship with performance. As part of AHRQ's Comparative Health System Performance (CHSP) Initiative, we developed new variables to describe whether health systems: (1) participated in alternative payment models (indirectly through participation by the systems' hospitals), including an Accountable Care

Organization (ACO) or a Medicare bundled payment program and (2) offered an insurance product, including any insurance product or a Medicare Advantage (MA) product.

METHODS: We used data from Leavitt Partners' 2016 Torch Insight tool to construct measures of system participation in ACOs. We used publicly available data from the Centers for Medicare & Medicaid Services (CMS) to construct a measure of system participation in a Medicare bundled payment model including the Comprehensive Care for Joint Replacement model and the Bundled Payments for Care Improvement initiative. We used the 2015 American Hospital Association Annual Survey to construct a measure of whether a system offered any insurance product and CMS's January 2016 MA Plan Directory to identify which systems offered an MA plan. The population was the 626 health systems in AHRQ's Compendium of U.S. Health Systems, 2016, and the system and non-system hospitals in the Hospital Linkage File. For the purposes of the Compendium, health systems include at least one hospital and at least one group of physicians that provide primary and specialty care and are connected with each other through common ownership or joint management.

RESULTS: In 2016, more than half of health systems (56%) participated in an ACO contract with Commercial and Medicare contracts being the most common (42% and 37%, respectively) compared to Medicaid contracts (10%). Nearly forty percent offered an insurance product with roughly twice as many systems offering an HMO or PPO product (31% each) than indemnity fee-for-service product (16%). Systems that participated in an alternative payment model or offered an insurance product tended to be larger, had a higher teaching intensity, and were investor-owned. System hospitals were more likely to participate in ACO contracts (44% of system hospitals vs. 13% of non-system hospitals) or a Medicare bundled payment model (28% vs. 8%).

CONCLUSIONS: These results show that in 2016, health systems had relatively high rates of participation in alternative payment models and insurance products, but with potentially important variation by system characteristics. This work illustrates how the Compendium of U.S. Health Systems can be used to study variation in health systems' characteristics and determine which characteristics are associated with better performance.

HEPATITIS C SCREENING MAY BE INADEQUATELY PERFORMED IN ADULTS SEEKING PREVENTIVE HEALTH CARE: NON-AFRICAN AMERICANS ARE LESS FREQUENTLY TESTED THAN AFRICAN AMERICANS

Ali Khan: Anna Stachura; Jenny Dave; Bedoor Alabbas; Praphopphat Adhatamsoontara; Abdullah Al-Asaad; Arun Muthiah; Daniel Szvarca; Karan Chawla; Nadeem Tabbara; Tina Boortalary; Andres Garza; Marie Borum. George Washington University, Washington, DC. (Control ID #3162861)

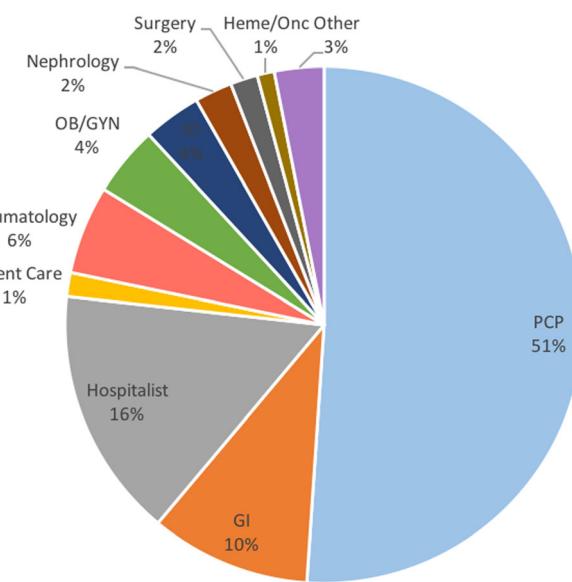

BACKGROUND: Despite US Preventive Services Task Force recommendations to perform Hepatitis C Virus (HCV) screening in adults born between 1945-1965, testing is inconsistent. All health care encounters provide an opportunity for HCV testing. Notably, adults pursuing colon cancer screening are interested in preventive care. Physicians who refer for or perform colon cancer screening have an opportunity to test for HCV. This study evaluated the rate at which adults undergoing screening colonoscopy had HCV testing and the physicians who ordered the HCV test.

METHODS: A retrospective chart review of all individuals born between 1945-1965 referred for colonoscopies during a one-year period at an academic medical center was performed. Patient age, gender, HCV screening status, and ordering physician were obtained. Individuals were excluded if they were not in the appropriate birth cohort. A confidential database was created using Microsoft Excel with statistical analysis set at <0.05 . The IRB approved the study.

RESULTS: In 2205 patients, 920 (42%) were male and 1285 (58%) were female (mean age 61.7 years) with 1181 (54%) African Americans and 930 (42%) non-African Americans. 964 (43.7%) had HCV screening. There

was no significant difference in HCV screening based upon gender (402 (43.7%) males, 562 (43.7%) females; $p=1.000$). Non-African Americans were screened significantly less than African Americans (385 (41.4%) and 555 (47.0%) respectively; $p=0.0111$). Primary care physicians (51.1%) performed significantly more HCV screening than hospitalists (15.7%; $p=0.0001$), gastroenterologists (10.0%; $p=0.0001$) and other specialty physicians (18.7%; $p=0.0001$).

CONCLUSIONS: In this study, HCV screening in individuals born between 1945-1965 was inadequately performed, with less than half seeking preventive health care being tested. There was also a disparity in HCV screening between non-African Americans and African Americans. While this study is limited based upon single institution design, it provides a basis for the development of interventions to improve HCV testing. It is important that all individuals at risk for HCV be tested with elimination of any potential bias in screening. Primary care physicians and gastroenterologists have the potential to improve HCV testing when referring for or conducting colon cancer screening. Innovative approaches are needed to optimize preventive care delivery.

HIGH VALUE CARE AND QUALITY IMPROVEMENT: A DEPRESCRIBING INITIATIVE IN RESIDENT PRIMARY CARE CLINICS

Joel C. Boggan^{2, 1}; Suchita S. Sata³; Alicia Clark⁴. ¹Duke University Health System, Durham, NC; ²Durham VA Medical Center, Durham, NC; ³Duke University Hospital, Raleigh, NC; ⁴Beth Israel Deaconess Medical Center, Wellesley, MA. (Control ID #3185986)

BACKGROUND: Patients taking multiple medications are often at risk of complications related to medication interactions. In addition, patients frequently desire to reduce the burdens of medication administration and costs related to complicated pharmaceutical regimens. In this quality improvement (QI) study, we sought to identify patients at high risk for polypharmacy in resident clinics and determine if education with audit-and-feedback initiatives could increase rates of conversations about medication discontinuation and actual cessation.

METHODS: The three resident clinics at a large internal medicine program were included in this study. An online interactive experience to guide the project was developed utilizing Microsoft Sharepoint™. Junior and senior residents participated in this mandatory residency-wide project as part of regularly scheduled ambulatory blocks during each half of the academic year 2017-18. After Phase 1, residents reviewed up to 20 of their primary care encounters for rates of conversations related to medication

discontinuation and actual discontinuation. Thereafter, residents were provided real-time statistics of their individual performance relative to peers at the clinic and residency level. Next, they were given the opportunity to set specific goals and methods for improvement. In Phase 2, chart review was re-performed with repeat real-time data presentation to assess whether audit-and-feedback methods and goal setting increased rates of medication discontinuation conversations and actions.

RESULTS: Overall, 1,559 unique patient encounters were reviewed during the study period (853 pre-intervention and 706 post-intervention) by a total of 72 residents. On average, patients in both phases were receiving similar numbers of medications prior to their reviewed visit (11.1 meds in Phase 1 vs. 10.9 in Phase 2, $p=0.58$). There were no statistically significant differences in the proportion of patients over the age of 65 years in each phase (42.7% vs. 47.0%, $p=0.09$), nor the proportion deemed by resident primary care physicians to be at-risk for polypharmacy (55.9% vs. 55.7%, $p=0.92$). While rates of discussing cessation of a medication within a clinical encounter increased by 32.3% between phases (28.1% in Phase 1 vs. 37.2% in Phase 2, $p<0.01$), no similar increase in actual medication discontinuation was found (19.1% vs. 20.8%, $p=0.39$).

CONCLUSIONS: Audit-and-feedback QI methods led to an increase in conversations regarding medication discontinuation in resident primary care encounters; however, rates of actual medication discontinuation did not increase. These findings may suggest that, even in patients deemed at high risk of medication complications, many medications may be necessary to manage chronic medical conditions. Alternatively, patients may require multiple conversations or encounters to reduce or eliminate certain medications (such as proton pump inhibitors or opioids) given chronic symptoms.

HIGHER PERCEIVED SOCIAL SUPPORT CORRELATED WITH LOWER BURNOUT IN MEDICAL STUDENTS

Brittany Smith; Justine E. Owens; Tabor E. Flickinger; John Schorling; Margaret L. Plews-Ogan; Rachel H. Kon. University of Virginia, Charlottesville, VA. (Control ID #3185641)

BACKGROUND: Each year, medical educators dedicate more effort towards preventing burnout in their medical trainees. The Maslach Burnout Inventory (MBI) assesses emotional exhaustion (EE), depersonalization (DP), and low sense of personal accomplishment (PA) as the three main determinants of burnout. Previous papers hypothesize personal life events, such as illness or death of family members may contribute to EE, and that workplace cynicism toward the chronically ill may be contributory to the development of DP. Other studies show social support from family, friends, fellow students, teachers, and social groups correlate negatively with mental health problems. We conducted a study to assess the relationship between perceived social support and burnout levels in medical students during each year in school to determine importance of structured social opportunities to promote trainees' wellness and reduce likelihood of burnout.

METHODS: All medical students at the UVA School of Medicine were sent an annual online survey from 2014-2018. The survey included the 22-item MBI, demographic information, and five items using a 5-point Likert scale to assess students' perception of support provided by their family, friends, faculty members, administration, and deans. Pearson correlation was used to measure the relationship between perceived support and burnout domains (EE and DP) for each year of training.

RESULTS: Of 2509 students eligible, 1371 surveys were completed for all years with response rates of 48%, 42%, 45%, and 44% for each year in school respectively. Fifty-two percent of participants who completed the survey were female. In year 1, of the five categories of support, perceived support from friends had the strongest inverse correlation with EE ($r=-0.312$, $p<0.000$). In year 2, perceived support from administration and faculty had a moderate inverse correlation with EE ($r=-0.353$, $p<0.000$ and $r=-0.330$, $p<0.000$, respectively). In year 3, perceived support from faculty and administration had moderate inverse correlations with EE ($r=-0.403$, $p<0.000$ and $r=-0.398$, $p<0.000$, respectively). In year 4, perceived support

from faculty and administration had moderate inverse correlations with EE ($r=-0.401$, $p<0.000$ and $r=-0.317$, $p<0.000$, respectively). Similarly categories of social support were significantly inversely correlated with DP, but were more strongly correlated to EE.

CONCLUSIONS: During the first year of training, perceived social support from friends seems to most strongly mitigate EE in medical students. However, as medical students enter their 3rd and 4th years in training, particularly when burnout is highest, perceived social support from faculty and administration seems to counter EE more. Further studies investigating students' specific definitions of social support from faculty, administration, and friends, may give educators insight into which social interactions are beneficial at lowering burnout levels at each stage of medical school.

HOME HEALTHCARE DELIVERY IN HEART FAILURE: WORKFLOW, CHALLENGES, AND POTENTIAL SOLUTIONS

Madeline R. Sterling¹; Nicola Dell²; Benedetta Piantella³; Jacklyn Cho⁴; Harveen Kaur¹; Emily Tseng²; Fabian Okeke²; Mikaela Brown²; Peggy B. Leung¹; Ariel F. Silva¹; Amy L. Shaw¹; Faith Wiggins⁵; Lisa M. Kern¹. ¹Weill Cornell Medicine, New York, NY; ²Cornell Tech, New York, NY; ³New York University, New York, NY; ⁴Cornell University, Ithaca, NY; ⁵1199-Home Care Industry Education Fund, New York, NY. (Control ID #3181586)

BACKGROUND: Reducing hospital readmissions for heart failure (HF) patients is a national priority. Data suggest that readmission rates are particularly high among HF patients who require home healthcare (HHC) after discharge. One possible reason is that the workflow of HHC may not be optimized. Since the exact workflow of HHC is not well described, pinpointing opportunities for interventions has been difficult. To better articulate the workflow of HHC for HF patients and identify challenges and opportunities for improvement, we elicited the perspectives of key stakeholders, including home health aides, who—despite being the minute-to-minute observers of HF patients—have not been included in research.

METHODS: We conducted a qualitative study using a combination of interviews and focus groups with home health aides, nurses, HF patients, family caregivers, physicians, social workers, home care agency leaders, and policy experts in NYC. We used a combination of purposeful and convenience sampling. To elicit participants' experiences with HHC in HF, we used a semi-structured topic guide. We also asked selected participants to draw their understanding of HHC post-hospitalization workflow for HF patients. Interviews were recorded, transcribed and analyzed thematically. Drawings were synthesized into a final image.

RESULTS: 80 participants were recruited from 10 home care agencies, 1 academic medical center, and 1 nonprofit organization. Participants described HHC for HF patients occurring in 6 steps, with home health aides playing a main role: 1) Transitioning from hospital to home; 2) Recognizing clinical changes; 3) Making decisions; 4) Managing symptoms; 5) Asking for help; and 6) Calling 911. For each step, challenges and solutions were identified. In Step 1, participants reported that care was poorly coordinated among providers, with information lost in translation: "*I send the discharge summary to the agency, but it never gets to the patient's aide.*" To address this, they proposed a handoff process between hospital and home providers. The leading issue for Steps 2, 3, and 4 was that despite providing the most patient care, home health aides do not receive HF training: "*Picking up on symptoms and knowing what to do requires training.*" Participants recommended a HF training course for home health aides. In Step 5, participants were frustrated by communication: "*I call the agency or the hospital, but I can't get through so I call 911!*" Due to this, many felt tech-based innovations could improve connectivity for the escalation of care. Lastly, participants felt that tackling these issues could reduce 911 calls (Step 6) and potentially readmissions.

CONCLUSIONS: Our findings suggest that HHC for HF patients occurs in a series of discrete steps, each plagued with different challenges. Rather than a one-size-fits-all approach, it is likely that a variety of different interventions will be required to optimize HHC delivery for HF patients in the post-discharge period.

HOME MODIFICATIONS AND AGING IN PLACE: RESULTS FROM THE NATIONAL HEALTH AND AGING TRENDS STUDY
Cynthia Schoettler^{1, 2}; Edward R. Marcantonio⁴; David M. Levine³.
¹BIDMC, Boston, MA; ²Veteran's Health Administration - Boston, Boston, MA; ³Brigham and Women's Hospital, Boston, MA; ⁴Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #3183132)

BACKGROUND: Most older adults wish to remain in their own homes, termed aging in place. Numerous barriers to this exist, including functional limitations and housing not designed to meet the needs of persons with limited physical abilities. Addressing functional limitations with home modifications (HMs) may be a way for older adults to delay transition out of their home to a more institutionalized setting (e.g., nursing home or assisted living facility).

METHODS: The National Health and Aging Trends Study (NHATS) is a nationally-representative longitudinal prospective cohort of community dwelling Medicare beneficiaries aged 65 years and older. Data from 2011-2017 were analyzed. Cox proportional hazards survival analysis was used to compare time living in the community of those with HMs to those without HMs. HMs were defined as the presence of at least one of: bath grab bar, toilet grab bar, shower seat, raised toilet seat, stair lift, or entrance ramp. Models were: unadjusted, minimally adjusted (age, gender, race/ethnicity, income, and education), heavily adjusted (minimally adjusted variables plus partner status, census division, living alone, number in social network, Medicaid, Tricare, self-rated health, number of comorbidities, recent hospitalization, recent fall, worry about falls, short physical performance battery (SPPB) score, and number of activities of daily living (ADLs) requiring help), and function only (falls, worry about falls, SPPB score and ADL help).

RESULTS: Data from 10,949 participants were analyzed. 65% of the participants had at least one HM in place at time of study entry, this increased to 81% by the time of participant exit from the community. At study entry those with HMs were more likely to be older (42% 80 yrs Vs 22% in the population without HMs; $p < 0.01$), female (59% Vs 54%; $p < 0.01$), Caucasian (69% Vs 62%; $p < 0.01$), widowed (34% Vs 25%; $p < 0.01$), have more comorbidities (mean sum comorbidities 3.74; 95% CI 3.67 - 3.80 Vs 3.07; 95% CI 2.99-3.14), lower mean SPPB score (6.57; 95% CI 6.47-6.68 Vs 7.94; 95% CI 7.80-8.08), and require help with ADLs (mean sum ADLs requiring help 1.36; 95% CI 1.33-1.39 Vs 1.12; 95% CI 1.10-1.14. Having a HM was associated with shorter time to institutionalization in unadjusted (HR 1.35; 95% CI 1.21-1.51) and minimally adjusted (HR 1.88; 95% CI 1.44-2.46) models. The function only model showed longer time to institutionalization (HR 0.74; 95% CI 0.65-0.84), but not in the heavily adjustment model (HR 1.30; 95% CI 0.92-1.84).

CONCLUSIONS: Multivariate survival analysis suggests that home modifications may delay transition to an institutionalized setting for those with reduced physical function. However, the effect of HMs may further be complicated by additional confounding by indication not adequately controlled for. More detailed study of the effect of home modifications on aging in place is needed.

HOMELESS VETERANS RATE PRIMARY CARE MORE FAVORABLY IN HOMELESS-TAILORED COMPARED TO MAINSTREAM PRIMARY CARE CLINICS: A NATIONAL SURVEY

Stefan Kertesz^{1, 3}; Audrey Jones^{5, 6}; Aerin DeRussy¹; Lillian Gelberg²; Ann E. Montgomery^{1, 3}; April E. Hoge¹; Allyson Varley^{1, 3}; Sally Holmes¹; Sonya Gabrielian²; Kevin R. Riggs^{1, 3}; Erika Austin^{1, 3}; John R. Blosnich⁴; Adiseshu Gundlapalli^{5, 6}; Adam Gordon^{5, 6}; Young-il Kim^{1, 3}.
¹Birmingham VA Medical Center, Birmingham, AL; ²VA Greater Los Angeles Health Care System, Los Angeles, CA; ³University of Alabama at Birmingham, Birmingham, AL; ⁴Pittsburgh VA Medical Center, Pittsburgh, PA; ⁵VA Salt Lake City Health Care System, Salt Lake City, UT; ⁶University of Utah, Salt Lake City, UT. (Control ID #3179350)

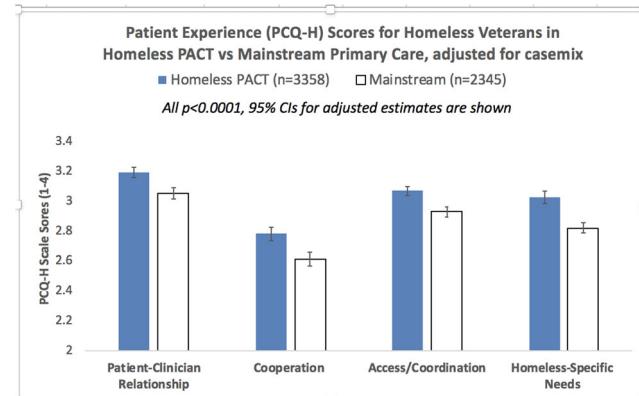

BACKGROUND: People experiencing homelessness face challenges in accessing primary care and difficulties related to care coordination and stigma.

In 2012, the Veterans Health Administration (VHA) implemented a patient-centered medical home model for Homeless Experienced Veterans (HEVs): Homeless Patient-Aligned Care Teams (HPACTs). HPACTs tailor services with smaller panels, outreach, dedicated staff, and support for tangible needs, along with linkage to social and other services. Some HEVs use HPACTs and some use Mainstream Primary Care (PC). We compared patient experience in these two service models using a validated patient experience survey.

METHODS: We chose a stratified, random sample of 14,352 HEVs in HPACT and Mainstream PC at 26 VA facilities. Response rate was 40% based on 4 mailings and up to 5 phone calls. The validated 33-item Primary Care Quality-Homeless (PCQ-H) measured Patient-Clinician Relationship, Perceived Cooperation among Caregivers, Accessibility/Coordination, and Homeless-Specific Needs. We used mixed effect linear regressions to estimate mean differences in PCQ-H scores, controlling for age, gender, race/ethnicity, unsheltered status, chronic homelessness, # of medical conditions, alcohol/drug problems, psychiatric medication, monthly income, mental distress, social support and chronic pain, adjusting for facility as a random effect.

RESULTS: Compared to HEVs in Mainstream PC, HPACT users were younger, more often male, unsheltered and chronically homeless. They also had more drug/alcohol problems, lower social support, worse emotional distress, and lower income. PCQ-H scores were typically favorable (about 3 on a 1-4 scale). However, mean scores for HPACT were superior to Mainstream PC on all scales: Patient-Clinician Relationship (3.19 vs 3.08), Cooperation (2.79 vs 2.65), Access/Coordination (3.07 vs 2.95) and Homeless-Specific Needs (3.02 vs 2.84), all $p < 0.001$. These differences persisted when controlling for covariates (Figure). The largest magnitude of association between PCQ-H score and any predictor was the comparison of HPACT and Mainstream PC.

CONCLUSIONS: HEVs rated HPACT PC more favorably than Mainstream PC despite characteristics that could make care more challenging. This survey, the largest among homeless Veterans to date, suggests benefits from tailoring PC design to a vulnerable population.

HOSPITAL BASED ENGAGEMENT OF PATIENTS WITH OPIOID USE DISORDER

Susan L. Calcaterra. University of Colorado, DENVER, CO. (Control ID #3186908)

BACKGROUND: Individuals with opioid use disorder (OUD) have high hospitalization rates which presents an opportunity to initiate OUD treatment in the hospital. Hospitalists care for most hospitalized patients in the United States, yet little is known about their practices and beliefs regarding OUD treatment. We hypothesized that OUD treatment varies widely among hospitalists, however, with sufficient support and training, hospitalists would routinely initiate medications for OUD and link patients to addiction treatment.

METHODS: From October through November 2018, we conducted an anonymous online survey of academic hospitalists across the US. We identified a convenience sample of Hospital Medicine Division Chiefs and requested they email the survey to their hospitalist peer networks using a snowball

sampling technique. The survey queried three domains: current OUD treatment practices, perceptions and beliefs about treating patients with OUD, and hospital barriers and/or processes for OUD management. We rated responses on a 4-part Likert scale or true/false and report descriptive statistics. Response rates are unknown due to snowball sampling techniques with online surveys.

RESULTS: Among 305 respondents, 295 completed the survey. Many respondents lived in the West (n=121, 56%) and practiced 5 years (n=130, 49%). Of the respondents, 82% (n=238) reported they "always/often" cared for patients with OUD, however 50% (n=142) "rarely/never" screened for OUD. Hospitalists reported feeling "very/somewhat unsure" using DSM-5 criteria to diagnose OUD (65%, n=186), though 63% (n=182) "strongly/somewhat agree" that they have the clinical skills to screen, diagnose and refer patients to treatment. Furthermore, 65% (n=188) reported that they always/often" refer patients to treatment for their opioid use disorder. Hospitalists were less confident about the medical management of OUD. Only 25% (n=71) reported that they "strongly/somewhat agreed" that they were comfortable prescribing buprenorphine and 50% (n=140) "strongly/somewhat agreed" that prescribing buprenorphine was outside of their scope of practice. Hospitalists reported "rarely/never" initiating buprenorphine in the hospital (89%; n=257) and "rarely/never" prescribed or recommended naloxone for opioid overdose reversal (58%; n=168). Hospitalists reported insufficient ancillary support to arrange for treatment referrals (n=174, 6%) and lack of addiction specialty support (n=113, 43%) as barriers to hospital-based OUD treatment. However, 86% (n=86) said they would routinely screen, diagnose and initiate treatment for hospitalized patients with OUD if they had access to an addiction specialist.

CONCLUSIONS: Hospitalists are well-positioned to provide lifesaving treatment to hospitalized patients with OUD. This could be accomplished by providing hospitalists with increased education regarding OUD, greater institutional support with dedicated ancillary staff to screen and refer patients to treatment, and access to an addiction specialist.

HOSPITAL CONSERVATION STRATEGIES AND INPATIENT INTRAVENOUS OPIOID USE DURING THE CURRENT NATIONAL SHORTAGE

Hemal N. Sampat; John Marshall; Christopher Fortier; Chana A. Sacks. Massachusetts General Hospital, Boston, MA. (Control ID #3183314)

BACKGROUND: Due in part to manufacturing problems, the US is experiencing a shortage of intravenous (IV) opioids. In response, many hospitals developed conservation strategies. The impact of the ongoing shortage and resulting hospital-based conservation efforts on the use of IV opioids is unknown.

METHODS: We evaluated pharmacy dispensing records for morphine, hydromorphone, and fentanyl (the three most commonly used IV opioids) for all inpatient units at a single, large academic medical center. We divided the study period into two phases: January 29 through March 7, 2018 (the "pre-shortage" period before the hospital's conservation efforts began) and March 8 through June 3, 2018 (the "shortage" period for which data are currently available). We used descriptive statistics to determine the median number of dosage units of each opioid that was dispensed each week. Conservation efforts instituted on March 7 included a warning to prescribers in the electronic health record system about the shortage and recommendations about pharmacologic and non-pharmacologic alternatives to IV opioids. We tracked three hospital-level, patient-reported quality metrics during the study period, as measured by the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey: overall patient satisfaction, communication about pain, and discussion of pain treatment.

RESULTS: During the study period, use of IV morphine decreased by 51%, from a median of 1158 weekly dispenses (IQR 870-1523) in the pre-shortage period to a median of 572 (IQR 412-742) weekly dispenses during the shortage. Use of hydromorphone decreased by 36%, from a median of 668 (IQR 568-1300) weekly dispenses to 426 (IQR 240-586) dispenses per week. The use of IV fentanyl increased by 26%, with a median of 397 (IQR 357-

432) dispenses per week to a median of 501 (IQR 456-523) dispenses per week. Quality metrics (assessed by top-box survey response) were similar during the study period: overall patient satisfaction (84% pre-shortage vs. 82% during the shortage), communication about pain (77% vs. 73%), and discussion of pain treatment (80% vs. 79%).

CONCLUSIONS: During the study period, there was a substantial reduction in overall use of IV opioids, with large reductions in IV morphine and hydromorphone use and a modest increase in IV fentanyl use. A larger sample over a longer duration of the shortage will be important to understand patients' perceptions of the associated changes. Conservation efforts developed during shortages may be useful to promote use of alternatives to IV opioids during non-shortage periods.

HOSPITAL VARIATION IN DIAGNOSTIC TESTING OF PATIENTS ADMITTED WITH SYNCOPE

Timothy Anderson; Grace A. Lin. University of California, San Francisco, San Francisco, CA. (Control ID #3185853)

BACKGROUND: Syncope accounts for 1% of emergency department (ED) with an annual cost of over \$2.5 billion. Although advanced diagnostic testing for low risk patients with syncope is not recommended due to low yield, such patients are frequently hospitalized. Little is known about variation in diagnostic testing patterns between hospitals and regions.

METHODS: We used State Inpatient Databases to examine all adults hospitalized from the ED with an admitting diagnosis of syncope in 2013 from 10 states reporting detailed procedure utilization. We calculated rates of advanced cardiac testing (echocardiogram, stress test, or diagnostic catheterization) and neuroimaging (head CT or brain MRI) for each hospital. Predictors of receiving imaging were assessed using a hierarchical mixed-effect regression models adjusting for patient-, hospital-, and region-level factors. We estimated the proportion of variation in testing explained by differences among patients, hospitals, and regions using variation partition coefficients. The etiology of syncope was identified by primary discharge diagnoses.

RESULTS: We identified 45,541 patients (67% age 65, 54% female) admitted for syncope from 486 hospitals in 73 hospital referral regions (HRRs) from 10 states. Over two-thirds of patients received neuroimaging (31,381, 69%) and 20,051 (44%) received advanced cardiac testing. Hospital-level rates of advanced cardiac testing varied widely (median hospital 48% of patients received testing, IQR 16%-82%) as did neuroimaging rates (median 72%, IQR 43%-84%). There was no correlation between hospital-level rates of neuroimaging and cardiac testing (Spearman correlation 0.09). After adjusting for case-mix, nearly half of the variation in hospital-level testing rates was explained by differences in hospital and regional practice patterns (Table). The majority of patients were discharged with unexplained syncope (28,069, 62%) and neither receipt of advanced cardiac testing nor neuroimaging was associated with an increased likelihood of being discharged with an identified cause of syncope ($P<0.001$ for both).

CONCLUSIONS: The performance of advanced cardiac testing and neuroimaging in patients admitted for syncope varies widely between hospitals, with nearly half of variation explained by differences in hospital and regional practice patterns. Wide variation in testing rates suggests that Choosing Wisely campaign goals of reducing low value testing are achievable but are likely to require targeted local interventions.

HOSPITAL-LEVEL CARE AT HOME FOR ACUTELY ILL ADULTS: A QUALITATIVE EVALUATION OF A RANDOMIZED CONTROLLED TRIAL

David M. Levine¹; Julia Pian²; Karthiyayini Mahendrakumar¹; Agustina Saenz¹; Jeffrey L. Schnipper¹. ¹Brigham and Women's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA. (Control ID #3184962)

BACKGROUND: Hospitals are the standard of care for acute illness management, but hospital care can be expensive, uncomfortable, and associated

with adverse events. Substitutive hospital-level care in a patient's home has been shown to lower cost, utilization, and readmission. However, evidence to explain how and why home hospital accomplishes many of these results is lacking. To best elucidate the inner workings of the intervention, we report an in-depth qualitative evaluation.

METHODS: We performed a randomized controlled trial comparing usual hospital care versus acute care at home for patients admitted via the emergency department with any infection, exacerbation of heart failure, chronic obstructive pulmonary disease, asthma, or several other specified internal medicine diagnoses. Patients randomized home had nurse and physician home visits, IV medications, remote monitoring, video communication, and point of care diagnostic testing. Between 1 and 30 days after discharge from either arm, we administered semi-structured interviews to elicit detailed patient experience, using a convenience sample of patients until we reached thematic saturation. We analyzed responses using NVivo via the constant comparative method with 2 coders, with discrepancies resolved by a third.

RESULTS: Of the 60 eligible patients, we interviewed 15 home patients and 13 control patients (47% of all eligible patients); no sociodemographic differences existed between those who were and were not interviewed, although control patients were slightly younger (median age 72 vs 77 years). Patients' experience clustered around 3 main themes: clinician factors, factors promoting healing, and systems factors. Both groups noted positive experiences with their clinicians, although the home group had fewer negative comments regarding interactions with physicians, nurses, and aides. Compared to control patients, home patients described more thematic factors promoting healing: improved sleep, increased physical activity, improved social support from family, and better environmental comfort. Regarding systems factors, control patients described more difficulties during their admission from the emergency department to the hospital floor (compared to home patients' experience of hospital to home), more negative experiences with technology (e.g., alarms from monitors), and more logistical difficulties in receiving care during their admission (e.g., roommates). Both groups noted difficulties with the discharge process, citing difficulty carrying out the proposed plan after discharge.

CONCLUSIONS: Patients who received hospital-level care at home experienced fewer negative experiences with the clinical team, more factors promoting healing, and fewer systemic logistical hurdles. Both noted difficulty with discharge after hospitalization. To our knowledge, this is first qualitative analysis of home hospital care and will serve to provide insights and improvements for future home hospital efforts.

HOSPITALIZATION, RE-HOSPITALIZATION, MORTALITY, AND UTILIZATION PATTERNS PREDICTED BY NOVEL HIGH-RISK PATIENT LATENT SUBGROUPS AND COMPLEXITY SCORES

Xinhua Zhao^{1, 4}; Sandeep Vlijan^{2, 5}; Matthew Maciejewski^{3, 6}; Donna M. Zulman^{7, 8}; Hongwei Zhang¹; Joshua M. Thorpe^{1, 9}; Ann-Marie Rosland^{1, 4}.

¹VA Pittsburgh Center for Health Equity and Promotion, Pittsburgh, PA; ²VA Center for Clinical Management Research, Ann Arbor, MI; ³Durham VA Medical Center, Durham, NC; ⁴University of Pittsburgh, Pittsburgh, PA; ⁵University of Michigan, Ann Arbor, MI; ⁶Duke University, Durham, NC; ⁷VA Palo Alto Health Care System, Menlo Park, CA; ⁸Stanford University, Stanford, CA; ⁹UNC, Chapel Hill, NC. (Control ID #3165380)

BACKGROUND: Latent groups have been described among high-risk complex patients. Before such groupings are used to inform clinical care, the ability of such groups to predict distinct health outcomes and utilization patterns over time should be established.

METHODS: We previously used Mixture Item Response Theory (MixIRT), a hybrid classification-dimensional modeling approach, to define 6 clusters of chronic comorbidities and group-specific patient theta ('complexity') scores among 934,787 VA primary care patients whose predicted probability of hospitalization over 12 months using standard VA prediction algorithms was $\geq 25\%$ during any week in 2014. Here we assess the associations of group membership and patient theta scores with rates of all-cause mortality, all-cause acute hospitalizations, and 30-day re-hospitalization in the year following

group assignment, in regression models adjusted for patient demographic characteristics. We also examined detailed VA utilization patterns among groups.

RESULTS: 81% of patients were matched with a group at a probability $\geq 80\%$. High-risk patient groups were characterized by high levels of Substance Use Disorder (SUD, 11% of patients assigned), Cardiometabolic Conditions (CM, 21%), Mental Health Conditions (MH, 14%), Pain & Arthritis (PA, 16%), Cancer (13%), and Chronic Liver Disease (12%). The overall rate of one-year mortality was 8% and VA hospitalization was 25%. 17% of hospitalizations led to a readmission within 30 days. Mortality varied significantly by group (SUD=reference: AOR (95%CI): Liver 3.2 (3.0, 3.3), Cancer 2.3 (2.2, 2.4), CM 1.6 (1.5, 1.7), PA 1.06 (1.02, 1.11), and MH 0.7 (0.66, 0.73)). One-year hospitalization rates ranged from 61 per 100 patients (Liver) to 31 per 100 patients (MH) (adjusted incidence risk ratio (AIRR), SUD=reference: Liver 1.27, Cancer 0.95, CM 0.88, PA 0.75, MH 0.6, all p<0.001). Among all hospitalizations (n=253,933), 30-day re-admission rate ranged from Liver 24% to MH 15%; (AIRR Liver 1.1, SUD reference, Cancer 0.99, CM 0.92, PA 0.82, MH 0.73, all p<0.001 except Cancer p=0.69). MixIRT derived patient theta scores independently predicted mortality (AOR 1.16, CI 1.15, 1.17), any hospitalization (AOR 1.17, CI 1.16, 1.17), and at least one 30-day re-hospitalization (AOR 1.29, CI 1.28, 1.30). Notable group utilization patterns included large variation in primary care use (range 5.4 PCP visits/year for MH to 4.2 for SUD, specialty care use (range 13 visits/year for Cancer to 4.8 for SA), and ED visit rate (range 2.7 visits/year for SA to 1.9 for Cancer).

CONCLUSIONS: MixIRT models were able to assign high-risk patients, previously in a single group defined by a homogeneously high risk score, to subgroups with distinct hospitalization, re-hospitalization, and utilization profiles. Intervention content and intensity could be tailored to group utilization profiles and patient theta scores. High rates of re-hospitalization were seen among groups not typically targeted in re-admission prevention programs (Liver, Substance Use).

HOW DO ONLINE SITES OF ACADEMIC MEDICAL CENTERS PORTRAY THE HARMS AND BENEFITS OF LUNG CANCER SCREENING AND WHAT STEPS DO THEY RECOMMEND FOR PATIENTS

Stephen Clark; Daniel S. Reuland; Daniel Jonas. University of North Carolina-Chapel Hill, Chapel Hill, NC. (Control ID #3175218)

BACKGROUND: The USPSTF recommends lung cancer screening to adults aged 55 to 80 years who have a 30 pack-year smoking history and currently smoke or have quit within 15 years, but not before a shared decision-making discussion of benefits and harms. Many medical centers publish online information on screening, making the public aware of their ability to perform it. However, because websites could influence patient perceptions of screening, some experts have cautioned about overly optimistic portrayal of screening in patient-facing materials. We evaluated the online information for the reporting of harms and benefits as well as recommended next steps for patients.

METHODS: We performed a standardized web search for publicly available information on lung cancer screening at academic medical centers affiliated with any of the 152 US allopathic medical schools. A single author reviewed webpages for the reporting of benefits, harms, and recommended next steps. We used descriptive statistics to summarize the findings.

RESULTS: Eighty-one institutions (53.3%) had publicly available information on lung cancer screening. Centers were more likely to report benefits than harms (98.8% vs. 56.8%, Table 1). Only 19 (23.5%) webpages specifically recommended patients weigh the benefits and harms of screening. Only 11 (13.6%) mentioned overdiagnosis. Seventy-six (93.8%) institutions listed follow up steps with only 16 (19.8%) specifically indicating patients should discuss benefits and harms with a PCP. Three (3.7%) stated harms and benefits would be discussed at a lung cancer screening specific appointment scheduled by the medical center.

CONCLUSIONS: Among academic medical centers' online publicly available information for lung cancer screening, a balanced message of both benefits and harms was often not provided, and harms were commonly ignored. Many centers do not guide patients toward a discussion of harms and benefits with a patients' primary provider. Continued study and refinement of published information in this area is needed to optimize value concordant patient decision making for lung cancer screening.

HOW DO RESIDENTS RESPOND TO UNANNOUNCED STANDARDIZED PATIENTS PRESENTING SOCIAL DETERMINANTS OF HEALTH?

Fariha Ansari¹; Harriet Fisher¹; Jeffrey Wilhite²; Kathleen Hanley²; Colleen C. Gillespie¹; Sondra Zabar¹; Lisa Altshuler¹. ¹NYU School of Medicine, New York, NY; ²New York University School of Medicine, New York, NY. (Control ID #3186372)

BACKGROUND: There is an increased awareness among healthcare professionals to discuss social determinant of health (SDOH) information with patients. However, the awareness does not necessarily translate into effective response to the situation. In order to better understand the nuances in such conversations between patients and providers, we reviewed qualitative responses from Unannounced Standardized Patient (USP) portraying patients with SDOH concerns who were seen as part of a study to investigate healthcare teams' management of SDOH information.

METHODS: USPs, representing six different clinical cases, were seen by residents at an urban safety-net hospital. Each case had SDOH issues (financial and housing insecurity, social isolation), and USPs were trained to provide such information in a systematic fashion in response to provider questioning. After the encounter, USPs completed a behaviorally-anchored, standardized checklist, and also entered their impressions of the encounter in free text. The focus of this study was to evaluate these comments using a qualitative approach, focusing only on those that addressed SDOH. 258 visits occurred from 2017-present, and 209 relevant comments were analyzed.

RESULTS: Three general themes emerged: residents' openness to discussion of SDOH, their understanding of how these issues related to presenting concerns, and how they responded to those concerns. Some providers did not explore SDOH prompts, e.g. "I don't think she cut me off, but she quickly moved on to her next question without further delving deeper", while others were more responsive and supportive e.g., the provider "is very open to hearing my situation, I was able to fully explain my situation clearly." Such provider behavior impacted trust and connection, e.g., "Doctor X had good communication skills, but I felt like he didn't really hear my full story" There were variations in how well providers related SDOH to medical symptoms, e.g. "he completely ignored my concerns about mold at home" [asthma case] vs. "His questions centered around possible anxiety this (housing issue) might be causing me." After acknowledgement, fewer providers provided specific information or referrals to address the problem. This lack of follow-up seemed to leave USPs feeling uncomfortable. Both empathetic comments and suggestions for actions influenced their sense of activation to manage their health post-visit.

CONCLUSIONS: Data from the USP visits indicate that there is a range of attention to and follow up on patient presentation of SDOH needs by trainees in clinical settings. Issues of both general communication skills, awareness of connection between SDOH and health, and awareness of local resources impacted provider behavior, which then had an effect on relationship with patients. The complex issues involved in addressing SDOH highlights the diverse training needs for learners.

HOW EMPATHY DIFFERS BY MEDICAL SCHOOL CLASS AND GENDER

Mario A. Scarpinato¹; Pinky Jha²; Kevin Schlidt¹; Kate Stark¹; Daniel Roadman¹; Devarshish Joshi¹; Sanjay Bhandari¹. ¹Medical College of Wisconsin, Milwaukee, WI; ²Medical College of Wisconsin, Milwaukee, WI. (Control ID #3172868)

BACKGROUND: Studies have found that empathy in medicine (clinical empathy) can improve patient outcomes. These outcomes include reducing metabolic complications in diabetic patients, increasing their treatment compliance, and improving patient outcomes for the common cold. Despite empathy's beneficial value in medicine, other studies indicate that empathy significantly declines during the third year of medical school and attribute this decrease to many facets of students' lives: fear of making mistakes, training distress, demanding curriculum, conflicting time commitments, sleep loss, and a hostile work environment. Seeking to better understand student experiences with clinical empathy at the Medical College of Wisconsin (MCW), we surveyed third and fourth-year medical students (M3 and M4) using a self-report measure. Our goals were to determine the student's perception of empathy's role in medicine, the quality of teaching on empathy and the best way to teach empathy. We compared the results between M3 and M4 students and between genders.

METHODS: A survey was distributed to M3 and M4 students via a school-wide email between August 2018 and September 2018. Responses were anonymous, and a response rate of 39% was achieved. A Chi-square analysis was performed to analyze differences between males and females as well as between M3 and M4 students.

RESULTS: 50% of M4 students (n=38) believed that working with attending physicians increased their understanding of the importance of compassion and empathy in patient care which was significantly more than the 34.3% of M3 students (n=36) (p-value=0.034). 100% of females (n=78) and 89.2% of males (n=91) believed that providing empathy and compassion in patient care improved patient outcomes (p=0.003). Gender preferences for empathy education methods also proved to be significantly different. Among females, 2.6% (n=2) felt that auditorium lectures were an effective method to learn empathy in medical school while 10.8% of males (n=11) felt it could be effective (p=0.035). Additionally, 53.8% of females and 32.4% of males felt that standardized patient encounters such as the objective structured clinical exams (OSCE) would be an effective medium for empathy education (p=0.004).

CONCLUSIONS: Our institution, and institutions across the country, can use this study to provide support for a change to education on empathy. Our data suggests that the current model of teaching empathy is not working for our students. The lack of awareness among medical students on the value of physician empathy is troubling. Our study provides direction for those changes and possible future intervention: increasing patient interaction and individualizing empathy education. As greater patient interaction appears to increase, not decrease, students' opinions on the value of empathy, and differences in female and male students' perceptions on the value of empathy and how they would like to be taught suggest the opportunity to personalize empathy education in the future.

HOW LONG SHOULD IT TAKE TO PROVIDE HIGH QUALITY PRIMARY AND SECONDARY PREVENTIVE CARE IN THE ERA OF TEAM-BASED MEDICINE AND POPULATION HEALTH?

Justin Porter¹; Cynthia M. Boyd²; Mohammed Reza Skandari¹; Neda Laiteerapong¹. ¹University of Chicago, Chicago, IL; ²JHU, Baltimore, MD. (Control ID #3183683)

BACKGROUND: Primary care providers (PCPs) have always been expected to provide quality preventive and chronic care for each of their patients, but studies have shown that many preventive and chronic care gaps exist. To address these care gaps, new strategies have emerged including, population-level approaches for completing preventive care gaps and increasing numbers of non-physician providers in primary care. To understand their implications, we updated previous calculations of the total amount of time a PCP would need to provide preventive and chronic disease care for a panel of 2500 patients on their own, as well as with team-based and population level strategies.

METHODS: We calculated the amount of time per day a PCP would have to spend to complete preventive and chronic care, if the PCP 1) alone, 2) with team-based, 3) with population-level, and 4) with team-based and population-level strategies were used to complete care

recommendations. We estimated times for a panel of 2500 patients with the age, gender, and racial distribution and chronic disease prevalence of the 2014 adult U.S. population. For preventive care, we used the list of United States Preventive Services Task Force Grade A/B recommendations for non-pregnant adults. We performed a literature review to ascertain the time necessary for a PCP and/or team member (e.g., nurse, medical assistant) to provide evidence-based care. We also collected evidence about population-level strategies for completing recommendations (e.g., mailers). For chronic care, we compiled a list of the 10 most prevalent diseases in adult primary care and performed a literature review to determine the number of PCP visits per year and time required per visit for each condition. We assumed that each chronic disease would require 10 minutes per visit if a specific time was not found.

RESULTS: For a panel of 2500 US patients, it would take a PCP 13.9 hours/day to complete preventive (10.6 hours/day) and chronic care (3.3 hours/day). If team-based and population-level strategies were employed, then PCPs would require 5.3 hours per day to complete preventive (2.0 hours/day) and chronic care (3.3 hours/day). Preventive care counseling tasks formed the majority of physician time saved, with that time shifted to Dieticians (5.7 hours/day) and Counselors (1.7 hours/day). Population based interventions only saved 0.2 hours/day.

CONCLUSIONS: We found that providing high quality primary care in the U.S. continues to require direct patient contact for longer than the average workday. However, incorporating evidence-based team-based strategies would reduce the work necessary to more feasible levels and allow PCPs to have time to complete administrative tasks, conduct shared decision-making and care for patients with complex medical illness.

HOW MEDICAL EDUCATORS USE ONLINE CURRICULA: DATA ANALYTICS FROM A GRADUATE MEDICAL EDUCATION CURRICULUM DISSEMINATION WEBSITE

John Geyer^{2, 1}; Anna Golob^{2, 1}; Cassandra Song³; Mayuree Rao¹; Joyce E. Wipf^{2, 1}. ¹University of Washington, Seattle, WA; ²VA Puget Sound, Seattle, WA; ³VA Puget Sound Health Care System, Seattle, WA. (Control ID #3183346)

BACKGROUND: Web-based asynchronous applications are increasingly used for dissemination of complex undergraduate and graduate medical curricula. Online analytic applications can provide curriculum developers with valuable data about usage, guiding future content revisions. A population health panel management medical education curriculum, developed at the Seattle Center of Excellence in Primary Care Education at VA Puget Sound (COE), includes electronic medical record best practice, inter-professional case-based discussions and chronic disease didactics. The curriculum, including competency domains and evaluation results of the curriculum, was ported to a website in December 2017 and has been disseminated to a limited group of national and international medical educators for the past 12 months with protected site access.

METHODS: Curriculum content was derived from a previously established population panel management series described elsewhere and in practice with VA-based residents in Internal Medicine and other health professions since 2011 in Seattle primary care and women's clinic. A web development software package was used to generate an HTML5/CSS website with video content hosted on YouTube and embedded in the site. Resources such as didactic PowerPoints, curricula handouts and computer screen shots were placed alongside 1-2 minute video clips. Google Tag Manager and Google Analytics were deployed to track user usage. Content was protected with SSH basic password protection.

RESULTS: 8 local and national sites at the VA and University of

Washington were given access to the website. 407 and 123 views of the home and password protected content pages occurred, respectively, from 1/1/18 - 12/28/18. Session duration averaged 1 minute and 49 seconds. Video content was viewed by 29 users with average view duration of 48 seconds per video. 21 users downloaded curricula resources. There have been positive reviews among a national cohort of medical educators. Comments include "easy to use interface" and "approachable content." One physician educator requested further clarification of one component of the curriculum regarding the integration of inter-professional providers.

CONCLUSIONS: About a fourth of users who visited the home page entered the password protected content domain. Current website restricted access likely limits the ability for users to access content due to password protection. Only a third of users viewed video content or downloaded resources. However, video content was viewed by many users at local and national COE teleconferences. To be determined will be how de novo users interact with site content. Comments, while positive, have directed efforts to clarify key points of curriculum. Future endeavors include broadening population for dissemination by removing password protection, revising content to increase user engagement and developing additional web-based curricula for other topics.

HOW MUCH IS ENOUGH? PHYSICAL ACTIVITY FOR YOUNG ADULT CARDIOMETABOLIC HEALTH

Heather R. Frank¹; Hillary Mulder²; Karishma Sriram¹; Taruni Santanam¹; Asheley C. Skinner³; Eliana M. Perrin³; Sarah C. Armstrong^{3, 2}; Eric Peterson²; Charlene A. Wong^{3, 2}. ¹Duke University, Durham, NC; ²Duke University Hospital, Durham, NC; ³Duke University School of Medicine, Durham, NC. (Control ID #3175938)

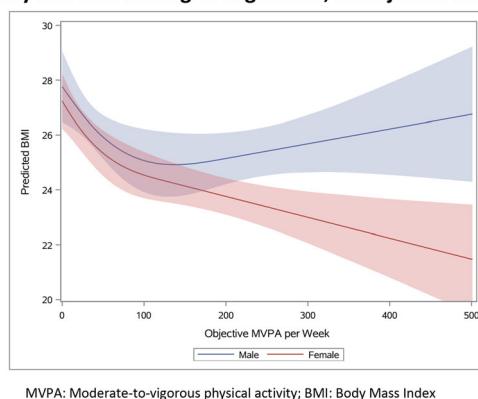

BACKGROUND: The 2018 Physical Activity (PA) Guidelines recommend 150 minutes weekly for adults. It is unclear if this activity level matches cardiovascular benefits for young adults (YA) transitioning from adolescence. We aim to determine the dose-response of PA measures on cardiometabolic health measures in YA.

METHODS: We examined YA (20-29 years) in the 2003-2016 National Health and Nutrition Examination Survey. Primary exposures were objective (accelerometer) and self-report weekly mean minutes of moderate/vigorous physical activity (PA). Primary cardiometabolic outcomes were systolic blood pressure (BP), diastolic BP, total cholesterol, high-density lipoprotein (HDL), body mass index (BMI), and maximal oxygen uptake (VO₂ Max). The dose-response relationship between each PA exposure and cardiometabolic outcome was assessed with unadjusted spline analyses; each pairing was tested for non-linearity using natural cubic splines, with non-linear relationships converted to 2-part piece-wise linear splines. Sex stratified outcomes were modeled using multivariable linear regression adjusting for sociodemographic characteristics. Mean estimated change is presented for 150-minute PA dose increases.

RESULTS: YA (N=6587) were 50% female, 59% white, 13.4% black. Among females, a slope change of the unadjusted dose-response curve for self-report PA occurred at 600 minutes for HDL, 725 minutes for BMI. With adjustment, a 150-minute increase in objective PA was associated with increased HDL of 5.4 mg/dL ($p=0.04$) and reduced BMI of 1.8 kg/m² ($p<0.001$); a 150-minute increase in self-reported PA was associated with increased HDL of 0.98 mg/dL ($p=0.01$) and reduced BMI of 0.23 kg/m² ($p=0.02$). Among males, the unadjusted dose-response curve slope changed for objective PA and BMI at 100 minutes. With adjustment, a 150-minute PA increase was associated with a VO₂ max increase of 5.4 ml/kg/min ($p<0.001$). We found inconsistent associations between PA and systolic BP, diastolic BP, and total cholesterol for males and females.

CONCLUSIONS: Achieving the advised 150 weekly minutes of PA was associated with improved HDL and BMI in females and VO₂ max in males. Some relationships indicated lower marginal cardiometabolic benefit of PA after a certain point. Future guidelines can account for the unique gender dose-response relationships among young adults.

Figure 1: Dose Response Relationship between Objective Physical Activity and BMI among Young Adults, Unadjusted Models

HOW PRECEPTORS IN AN INTERNAL MEDICINE CONTINUITY CLINIC DEVELOP TRUST IN RESIDENTS

John Penner; Karen E. Hauer; Katherine Julian; Leslie Sheu. University of California, San Francisco, San Francisco, CA. (Control ID #3186131)

BACKGROUND: Trust is a growing area of interest because it informs supervision. Most research on trust focuses on the inpatient setting. However, trainee responsibilities, team structure, teaching, and trainee-supervisor relationships differ in continuity clinics. As medical education accreditation bodies increasingly emphasize the need for improved continuity clinic education, it is important to understand how trust develops in this setting to provide trainees developmentally-appropriate graded autonomy. We aim to understand how faculty preceptors in internal medicine continuity clinics develop trust in residents, and how trust affects supervision.

METHODS: This is a qualitative study using thematic analysis of semi-structured interviews with continuity clinic preceptors in an internal medicine residency program. Interviews address preceptors' views of trust, resident characteristics that build or erode trust, and supervisory behaviors that inform and vary with trust.

RESULTS: We have interviewed eight preceptors; data collection is ongoing. Preliminary results show preceptors determine trust through residents' knowledge of patients, clinical judgment, presentation organization, and reliability in follow-up. Longitudinal relationships and observation of residents both conducting patient encounters and handling virtual care (lab results, patient messages) inform trust. Resident openness about knowledge gaps and desire for feedback support trust development. With greater trust, preceptors promote resident autonomy by probing less about background information, patient history, and physical exam findings, providing less directive guidance on care plans, and shifting their focus towards teaching. Challenges to developing trust include preceptors' lack of familiarity and limited contact with residents' patients and limited preceptor continuity across resident clinic sessions. Despite noting their importance, preceptors cite difficulty in observing residents, especially their execution of virtual care, and engaging in feedback conversations as often as they would like to.

CONCLUSIONS: Factors unique to the continuity clinic setting, including longitudinal faculty interactions with residents and the

growth of virtual care, influence trust formation. Areas of tension for preceptors lie in the fact that behaviors and interactions most conducive to trust development are also among the most difficult to observe and experience. Strategies to create continuity in oversight of in-person encounters and virtual patient care, foster longitudinal relationships, and normalize direct observation and feedback can align trust and supervision in continuity clinics of internal medicine residency programs.

HOW SHOULD WE CARE FOR PATIENTS WITH HIV AND COMORBIDITIES? A MULTISITE QUALITATIVE STUDY OF HIV CARE IN US DEPARTMENT OF VETERANS AFFAIRS

Barbara G. Bokhour^{1, 2}; Gemmae Fix^{1, 2}; Steven Asch⁸; Rendelle Bolton¹; Kelly Dvorin¹; Allen L. Gifford^{9, 3}; Justeen Hyde¹; Keith McInnes^{1, 2}; Amanda Midboe⁷; Victoria A. Parker^{1, 4}; Avy A. Skolnik^{1, 5}; Juliet Wu¹; Michael Ohl⁶. ¹Edith Nourse Rogers Memorial Veterans Hospital, Bedford, MA; ²Boston University School of Public Health, Bedford, MA; ³Boston University, Boston, MA; ⁴U of New Hampshire, Durham, NH; ⁵University of Massachusetts Amherst, Amherst, MA; ⁶Iowa City VA Healthcare System, Iowa City, IA; ⁷VA Palo Alto Health Care System, Menlo Park, CA; ⁸VA/Stanford, Menlo Park, CA; ⁹Boston VA Healthcare System, Boston, MA. (Control ID #3185155)

BACKGROUND: HIV is a chronic manageable condition, however as patients age comorbidity management often becomes the highest priority. Whereas care for these patients previously was concentrated solely in infectious disease or HIV specialty clinics, there has been a shift towards co-management between HIV specialty care and primary care. It is unclear how patients in HIV specialty care only vs. co-management fare with regards to HIV and comorbidity quality of care. Moreover, care provided in patient-centered medical homes (PCMH) is associated with higher quality. Thus, we sought to understand how variation in HIV care delivery was aligned with PCMH-principled care, and how comorbidity and HIV care quality relate to the structures and processes of care.

METHODS: We profiled 144 US Department of Veterans Affairs Medical Centers (VAMCs) on HIV quality (viral control), physical comorbidity care quality (e.g. HbA1C) and mental health care quality (e.g. guideline concordant depression care) using medical record data. We selected a purposive sample of 8 VAMCs high and low in these quality indicators. We conducted in-depth qualitative site visits, blinded to sites' quality designation, including: 1) patient interviews (n= 60); 2) HIV care team interviews (n=60); 3) direct observation of clinic processes and team interactions (n=22); and 4) direct observations of patient-provider clinical encounters (n=45). We coded all using both a priori constructs from PCMH principles and emergent codes. We constructed individual site templates to reflect care according to PCMH principles, observed processes and structures of care. We then revealed quality profiles and examined relationships between templated descriptions and level of quality.

RESULTS: Across variation in sites' structures and process of care, three main findings emerged. First, the sites highest and lowest in both HIV and comorbidity quality demonstrated clear differences in provision of PCMH-principled care. The highest site provided greater team-based care, comprehensiveness of services, patient-centered care, data-driven care and engaged in continuous improvement. Second, sites with higher HIV care quality attended more to psychosocial needs, either via HIV clinic team-based care or through coordination with psychosocial services outside the clinic. Third, comorbidity quality was not directly related to PCMH principles. Rather, comorbidity care was better managed in sites that had explicitly created structures and consistent processes for such care, regardless of

whether care was provided in HIV or primary care clinics.

CONCLUSIONS: Our multisite study using several sources of qualitative data shows that comorbidity and HIV care quality relate to different structures and processes of care. Providing care aligned with PCMH principles, integrating psychosocial needs into care, and establishing explicit consistent approaches to comorbidity management are critical for optimal HIV and comorbidity care quality and outcomes.

HOW WELL DO NEWLY ARRIVED INTERNS INTERPRET ECG'S

Leonardo L. Zelaya Castillo; Adam Horblitt; Gabriela Andries; Zahava Farkas; Michael Karass; Jason Goutis; Rebecca Newman; Merita Shehu; Melissa Gennarelli; Leanne Forman; Srikanth Yandrapalli; Christopher Nabors. Westchester Medical Center, Valhalla, NY. (Control ID #3161259)

BACKGROUND: Resident physicians are often the first clinicians to review an ECG and to make critical initial management decisions. Thus, it is essential that residents are able to rapidly interpret urgent findings on ECG.

METHODS: 17 ECG's which were believed to demonstrate either normality or a primary diagnosis were identified. This content was based upon the ECG types identified by Jablonover, and Stagnaro-Green.¹ The ECG's were pilot tested by 3 chief residents and 2 faculty members for clarity and ease of diagnosis. All 34 interns were asked to take the test over a two day span during the second month of training without using any reference materials.

RESULTS: Details in table 1. Trainees rated their preparedness to interpret ECG's (1, not well to extremely well, 5) at mean 2.34 and how intensively their medical school had focused on ECG training (1, not intensively to very intensively, 5) at 2.58. In medical school 29 respondents (88%) had a moderate or considerable amount of self-learning and 28 (85%) a small or moderate amount of classroom teaching and lectures; 30 (94%) had very little to only a moderate amount of hands on clinical training or small groups sessions 32 (97%). Compared to those who had a moderate amount of classroom training in medical school, those who had very little scored lower (59%, SD 25%) versus Mean: 75%, SD 17%). Of those who rated their preparedness to interpret ECG's at the second highest or highest level on a five point scale, the mean score was 90%, SD 10%. Of those who believed their medical school focused on ECG training at the second highest or highest intensity, mean scores were 72% SD 19%.

CONCLUSIONS: In this study, the ability to accurately identify important ECG patterns varied widely. Testing of early trainees may permit a targeted approach to teaching ECG's. Further study may permit an association to be identified between types of pre-residency ECG training experiences and subsequent competence in ECG interpretation during residency training.

HUNGER IS HEALTH: THE ASSOCIATION BETWEEN FOOD INSECURITY AND TYPE 2 DIABETES IN AN URBAN, SAFETY NET HOSPITAL PATIENT POPULATION

Meghana Anugu; Emily A. Kaltz; Jada C. Bussey-Jones. Emory University, Atlanta, GA. (Control ID #3185801)

BACKGROUND: Food insecurity remains a pressing public health issue. Literature suggests food insecure individuals are at greater risk for developing type 2 diabetes mellitus (T2DM), a condition associated with increasing morbidity and mortality in the United States. We aim to estimate the prevalence of food insecurity and how it relates to T2DM status in an urban, safety net hospital setting.

METHODS: We conducted a cross-sectional survey of 323 patients in the Primary Care Center at Grady Memorial Hospital (GMH), in Atlanta, GA from January 2016 to March 2017. Survey included demographic information including age, sex, race, household income, number of people in the household, and zip code, items to assess food insecurity, SNAP utilization, and diabetes status. An affirmative response to either question in the USDA 2-item food security screener was classified as food insecure, which has been previously validated as 97% sensitive. Primary outcome was a combined variable of prediabetes and type 2 diabetes.

RESULTS: The overall prevalence of food insecurity among the study sample was 53.5%. Considering diabetes status, food insecurity status was 37.5% and 62.5% among non-T2DM and T2DM patients, respectively. In multivariable logistic regression analyses, the odds of having diabetes was 2.6 times greater (95% CI 1.7-4.1) among food insecure patients compared to food secure patients. The effect remained statistically significant after controlling for sex, race, and income [2.6 (95% CI 1.5-4.4)]. Gender significantly modified the association between food insecurity and diabetes with an increased odds of diabetes among men with food insecurity [odds ratio 5.1 (95% CI 2.5-9.8)] compared to women [odds ratio 1.5 (95% CI 0.8-2.8)].

CONCLUSIONS: The prevalence of food insecurity in our sample was greater than four times the national average of 11.8%. This likely reflects the disparities and needs facing the patients of an urban, safety net hospital setting. There is a clear association between food insecurity and T2DM in the patient population studied. Further, our finding that gender significantly modified food insecurity and T2DM may reflect the differences in coping mechanisms between men and women who are in poverty and food insecure. For example, it has been suggested in the literature that men who are food insecure are less likely to access SNAP services. Given the high prevalence of food insecurity and the association between food insecurity and T2DM, we assert that initiatives to address T2DM need to consider food insecurity as an important and potentially intervenable variable. Initiatives to address this may include screening for food insecurity in patients with diabetes and food as medicine as an adjunct to diabetic treatment plans.

HYPERTENSION CARE DELIVERY IN RESOURCE-LIMITED SETTINGS: A LITERATURE REVIEW

Daniel C. Mays¹; David J. Heller¹; Rose C. Nanyonga². ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Clarke International University, Kampala, Uganda. (Control ID #3185472)

BACKGROUND: Hypertension, along with other non-communicable diseases, poses a significant burden of morbidity and mortality in low- and middle-income countries (LMICs) around the world. Health systems in LMICs are faced with the challenge of delivering care to prevent and treat such diseases with limited resources. There is a growing body of evidence on unique approaches to managing hypertension in resource-limited health systems, but these data have not been formally synthesized. This literature review aims to summarize high quality evidence through a systematic exploration of existing literature on hypertension care delivery in resource-limited settings.

METHODS: We conducted a systematic literature search using primarily the PubMed and Scopus databases along with grey literature databases. Title and abstract keywords as well as Medical Subject Heading (MeSH) terms focused the search on interventions addressing non-obstetric systemic arterial hypertension in adults in LMICs throughout the Global South. Titles and abstracts were systematically reviewed and rated according to relevance to the study aim. The most relevant publications underwent a focused in-depth analysis.

RESULTS: The search yielded 857 unique and relevant publications issued between 1970 and 2018. After title and abstract review, twenty highly relevant publications were selected for in-depth analysis, and among these were twelve original research studies and eight literature reviews. The original research studies evaluated interventions including task-shifting, community-based health insurance and clinical decision-making support tools to manage hypertension. The majority of these studies demonstrated significant blood pressure reduction in the intervention groups. Seven of the eight reviews were systematic and their topics included task-shifting, health-oriented mobile technology (mHealth), lifestyle change and community-based interventions to address hypertension. The strongest evidence supports, firstly, shifting care delivery tasks to non-physician health workers who address hypertension as part of organized teams with care escalation pathways according to clinical qualification. Secondly, there is strong evidence supporting decision-support tools and standardized clinical guidelines, commonly through novel utilization of technology.

CONCLUSIONS: Regarding hypertension care delivery in resource limited-settings, published evidence notably supports task-shifting within organized care teams and utilizing clinical decision-making support tools. Where health systems face limited capacity to manage the population burden of hypertension, these approaches were both feasible and effective. Given the range of contexts in which they were implemented, these approaches are likely applicable to a variety of health system settings in both resource-rich and resource-limited countries.

HYPERTENSION MANAGEMENT IN AN INTERNAL MEDICINE RESIDENT CLINIC: A QUALITY IMPROVEMENT INITIATIVE

Elaine Hutchison¹; Charlotte Lin¹; Christine Moorehead²; Emily D. Fondahn³. ¹Washington University, St. Louis, MO; ²Barnes-Jewish Hospital, St. Louis, MO; ³Washington University, St Louis, MO. (Control ID #3181892)

BACKGROUND: Hypertension is an important modifiable risk factor for cardiovascular disease. The Barnes-Jewish Hospital Primary Care Medicine Clinic is an academic internal medicine resident clinic affiliated with a tertiary referral center with an average 1960 patient visits per month. Clinic data shows about 62% of our patients have a diagnosis of hypertension. Our quality improvement project sought to improve the percentage of hypertensive patients with controlled blood pressure from a baseline of 60.7% to 80.0%.

METHODS: We defined controlled blood pressure as less than systolic 140 mmHg and diastolic 90 mmHg. Baseline and post-intervention data were collected through our electronic medical record (EMR). Blood pressure data was not readily available prior to June 2018 due to a change in EMR platforms. Interventions using a Plan-Do-Study-Act (PDSA) model were developed and prioritized in several multi-disciplinary meetings. The first PDSA cycle involved changing the nurse hypertension clinic referrals from paper to electronic to increase use of this resource by residents. In this clinic, a nurse measures blood pressure, consults with a resident if blood pressure is uncontrolled, and educates patients regarding lifestyle changes and blood pressure goals. Patients can follow up weekly until they have reached their goal blood pressure. Clinic nurses, pharmacists, residents, attendings, and information technology were involved in making this change.

RESULTS: The baseline percentage of patients with controlled hypertension was 60.7% from June to mid-September 2018. In September, when the electronic referral system was implemented, the percentage of patients with controlled hypertension improved to 64.5% but dropped to 61.3% in October and 57.0% in November. The average number of visits scheduled in the nurse hypertension clinic

monthly prior to EMR change was 150. Post-EMR change, there were 55 scheduled visits in June 2018, increasing to 95 in September, 139 in October, and 127 in November. Improving blood pressure control through this program is complicated by a high no-show rate to these appointments: 43.6% in June 2018 increasing to 50.3% in October and 48.0% in November. Prior to June 2018, the average no-show rate was 37%.

CONCLUSIONS: Our initial PDSA cycle increased the number of referrals to the nurse hypertension clinic to the pre-EMR transition baseline without sustained improvement in blood pressure control. We anticipate more substantial improvement as residents and staff become increasingly familiar with the referral process. The high no-show rate limits the effectiveness of this intervention and future PDSA cycles should consider this as an area for improvement. Our next PDSA cycles will focus on developing a hypertension documentation template within the EMR to facilitate communication between residents during transitions of care and distribution of ambulatory blood pressure monitors to patients.

IDENTIFYING CAUSES OF MISSED COLONOSCOPY APPOINTMENTS AT A SAFETY NET HOSPITAL

Michael A. Yu; Gordon T. Robbins; Saraubh Chawla; Erica Heiman. Emory University School of Medicine, Atlanta, GA. (Control ID #3183667)

BACKGROUND: In the US, colorectal cancer (CRC) remains the 4th most common cancer among men and women, and the 2nd leading cause of cancer deaths. CRC-related mortality has decreased due to better CRC screening rates. Nationally, 65% of the population eligible are up-to-date with recommended CRC screening. Grady Health System is a large, urban safety net hospital in Atlanta, GA. Overall CRC screening rates of Grady Primary Care Center patients is 55%. In an effort to improve CRC screening rates, we have implemented multiple interventions including offering Fecal Immunochemical Tests, educating providers via resident-run teaching sessions, engaging patients in waiting room conversations about CRC screening options, and streamlining our EMR. Despite this, our screening rates are still below the national average. One issue identified was high no-show rates to colonoscopy appointments. No-show rates from 2 other safety net systems were 27-29%. We hypothesize various contributors to this including scheduling issues, socioeconomic hardship, health illiteracy, challenges with completing colon prep, and inadequate resources for transportation. We explored this further by surveying patients with incomplete colonoscopy appointments.

METHODS: After we achieved IRB determination, we worked with the Grady Outpatient Endoscopy Center to identify patients who did not complete their colonoscopy appointments. We contacted these patients and, using a scripted questionnaire with open and closed-ended questions, surveyed them about why they were unable to complete their colonoscopies.

RESULTS: Our preliminary data reflects incomplete screening colonoscopies over a one-month period. There was a total of 30 incomplete colonoscopy visits and we were able to contact and survey 25 of these patients. Of these, 92% were no-shows, whereas the other 8% were incomplete prep or wrong arrival time. 92% of patients surveyed were aware of the appointments and similarly, 92% felt that they were provided with adequate notice. Transportation was cited as a problem for 56%. 20% of patients missed due to personal health problems, while 28% missed due to family obligations or emergencies. 16% cited financial issues, including inability to afford copay or prep costs. 24% of patients had scheduling issues, such as double-booked appointments. 20% of patients had problems with prep being incorrectly prescribed or not prescribed at all.

CONCLUSIONS: At Grady, patients failed to attend colonoscopy appointments despite possessing knowledge of the schedule and adequate reminders. Patients cited transportation, personal health problems, finances, and family obligations as barriers. However, double booking or failure to prescribe prep suggest that improvements can be made in execution from the health system perspective. Furthermore, providing financial aid may benefit those unable to afford visit copay and colon prep costs. We hope to expand on this data and use it to implement changes to reduce no-shows and increase CRC screening rates.

IDENTIFYING OUTLIER PRIMARY CARE PRACTICES TO REDUCE HIGH-COST UTILIZATION: A POSITIVE DEVIANCE APPROACH TO UNDERSTANDING THE PERSISTENCE OF HIGH-PERFORMANCE IN THE PATIENT-CENTERED MEDICAL HOME

Ashok Reddy^{2, 1}; Linnaea C. Schuttner^{2, 1}; Eric Gunnink²; Karin M. Nelson^{2, 1}. ¹University of Washington, Seattle, WA; ²Department of Veterans Affairs, Seattle, WA. (Control ID #3173936)

BACKGROUND: Veterans Health Administration (VHA) and Medicare measure primary care clinic performance based on rates of high-cost utilization including emergency department (ED) visits and hospitalizations. Yet, our understanding of high performing primary care clinics ("positive deviants") associated with low utilization rates is limited. Our primary objectives were to determine: (1) how positive deviant clinics who exhibited low rates of ED visits or hospitalizations in the baseline year persisted in subsequent years (2) the impact of adjusting for patient or clinic characteristics on the persistence of high performance among VHA primary care clinics.

METHODS: We used a cross-sectional design using annual data from 2012-2017 from the VHA Corporate Data Warehouse. We first calculated the observed over expected (O/E) ratio of hospitalizations (or ED visits) by clinic site for a baseline year. Expected utilization was calculated as patients per site multiplied by the national mean hospitalization or ED visits per year. We limited ED visit analysis to clinics with on-site EDs. We defined high-performance as the lowest 10% of clinics by O/E ratio in a baseline year. Next, we determined the number of high-performing clinics that persisted in the top decile in the following 5 years. Finally, we used a mixed effects model to determine the impact of patient (age, sex, race/ethnicity, comorbidity) and clinic (size, location) characteristics.

RESULTS: We analyzed hospitalizations at 899 clinics and ED visits at 144 clinics. A greater proportion of patients at high-performing clinics were younger, white, urban residents, and were cared for at community-based outpatient clinics. Of clinics initially identified as high-performing in 2012, we found 40 of 89 clinics for hospitalizations, and 9 of 25 clinics for ED visits were persistent high-performers. For this baseline year, high-performing clinics had on average 18 hospitalizations per 1000 patients and 229 ED visits per 1000. Between 2013-17, high-performing clinics had on average 14 hospitalizations and 221 ED visits per 1000. In 2012, clinics consistently below the top performers had 123 hospitalizations per 1000 patients and 661 ED visits per 1000. Between 2013-17, these clinics had 116 hospitalizations and 668 ED visits per 1000. After adjusting for patient and clinic characteristics, we did not find persistent primary care clinic performance outliers in either outcome of ED visit or hospitalizations.

CONCLUSIONS: Our findings suggest that many clinics persist as high-performing outliers with persistent low ED and hospital utilization. However, most of this persistence is related to non-modifiable patient and clinic-level characteristics. This implies that the usual next step in a positive deviance approach - qualitatively studying high performers to generate hypotheses about why these practices are successful - may not be useful in identifying strategies to reduce high-cost utilizations.

IDENTIFYING RACIAL/ETHNIC DISPARITIES IN INTERHOSPITAL TRANSFER

Evan Shannon¹; Jeffrey L. Schnipper¹; Stephanie Mueller². ¹Brigham and Women's Hospital, Boston, MA; ²Brigham and Women, Boston, MA. (Control ID #3185287)

BACKGROUND: Racial/ethnocultural inequities have been demonstrated throughout our health care system. Their presence among patients who undergo interhospital transfer (IHT) to receive more specialized care is poorly understood. We evaluated the association between patient race/ethnicity and IHT to identify potential disparities in this care transition.

METHODS: We performed a cross-sectional analysis of 2016 data from the National Inpatient Sample (NIS), the largest publicly available all-payer inpatient health care database in the United States which yields national estimates of hospital inpatient admissions. All adult patients were included. The primary outcome was IHT, defined as transfer to another acute care facility. The primary predictor was race, categorized as traditionally underserved racial/ethnic minority groups (Black, Hispanic, Native American) versus other (White, Asian, Other). We used logistic regression models to obtain odds ratio IHT by race, adjusting for patient and transferring hospital characteristics, including patients' age, sex, and insurance, median household income by zip code, mortality risk by diagnosis-related group (DRG), Elixhauser comorbidity index, hospital teaching status, region and bedsize. We performed secondary analyses using individual race/ethnicity categories.

RESULTS: There were a total of 6,037,727 unique admissions in the cohort representing 25,238,650 admissions nationally. 120,396 (2.4%) patients were transferred to an acute care facility. Among those transferred, 46.2% were female, 72.7% were white, 13.3% were Black and 8.4% were Hispanic. Minority patients had a lower odds of transfer compared to other groups (OR 0.75, 95% CI 0.72-0.78). Multivariable logistic regression adjusting for patient characteristics also revealed a lower odds of transfer (OR 0.83, 95% CI 0.79-0.86). However, when further adjusted for hospital characteristics, this association was no longer significant. In secondary analysis, Hispanic ethnicity was associated with lower adjusted odds of transfer compared to White patients (OR 0.94, 95% CI 0.90-0.98).

CONCLUSIONS: In this nationally representative sample of patients, we found that minority race/ethnicity, and Hispanic ethnicity in particular, was associated with lower odds of IHT. These findings remained after adjusting for patient characteristics, but lost significance after also adjusting for hospital characteristics, suggesting that existing racial disparities may be mitigated in part by factors affecting the hospitals to which minority patients present. Additional research is needed to further explore the drivers of these inequities.

IDENTIFYING RISK FACTORS FOR HYPOGLYCEMIA TO PREVENT ADVERSE OUTCOMES AMONG HOSPITALIZED PATIENTS

Corinne F. Levitus³; Julie Anne L. Gemmill³; Leena Shah¹; Marissa A. Wolfe³; Alexander Gee³; David T. Harris²; Nancy A. Wichtendahl²; Barbara M. Mills²; Joshua D. Miller³. ¹Montefiore Medical Center - Albert Einstein, Paramus, NJ; ²SUNY Stony Brook University Hospital, Stony Brook, NY; ³Renaissance School of Medicine at Stony Brook University, Stony Brook, NY. (Control ID #3162799)

BACKGROUND: Diabetes affects 30.3 million people in the US, and 25% of total hospital days are incurred by patients with diabetes. Among hospitalized adults, diabetes is considered a chronic secondary diagnosis. As the population of patients with diabetes grows, so does the potential for adverse events during hospitalization. Previous studies have shown that both hyper- and hypoglycemia are associated with poor outcomes in broad populations of hospitalized patients, including increased morbidity

and mortality. Hypoglycemia occurs in 3.5-10.5% of patients on the general medical floors and in 12-18% among patients with diabetes, owing in part to focus on glycemic control in patients with diabetes. Moderate glycemic control prevents microvascular complications and may reduce long-term cardiovascular complications; however, results from the ACCORD trial have shown that very intensive glycemic control may increase risk of mortality. Risk of hypoglycemia is especially pronounced in elderly patients with advanced duration of diabetes. As the population of adults with diabetes continues to expand, emphasis should be placed on identifying patients at risk for hypoglycemia and individualizing treatment strategies and glycemic targets to avoid adverse outcomes. We sought to identify patients with hypoglycemia preceding acute clinical deterioration requiring urgent response by our institution's Rapid Response Team (RRT), a multidisciplinary modality that aims to rapidly assess, monitor, and reverse clinical deterioration.

METHODS: We performed a retrospective chart review of three years of data acquired by our institution's RRT. We identified 95 hospitalized patients who underwent a "rapid response" due to hypoglycemia (point-of-care capillary glucose or serum glucose <70 mg/dL). We performed a multivariate analysis to identify contributors to poor outcomes (defined as all-cause mortality) following a hypoglycemic event.

RESULTS: Patients found to have significantly higher all-cause mortality following RRT for hypoglycemia ($p < 0.05$) were 65 years or older, had lower blood pressure, lower median hemoglobin A1c, higher AST and INR, longer hospital length of stay, were more likely to be NPO, and had a higher percentage of having an RRT in the morning. Patients who had a glucose level <41 mg/dL at time of RRT had higher rates of insulin use during admission when compared to individuals with higher glycemia.

CONCLUSIONS: As the diabetes epidemic worsens and more patients are hospitalized with the disease, it is critical that clinicians identify and manage risk factors for hypoglycemia. Our study identified several risk factors that were associated with all-cause mortality. Our findings support previous research that tight glycemic control can be detrimental to elderly patients. Based on our results, further research is needed to identify systems-based strategies for risk-stratification and prevention of inpatient hypoglycemia and improvement of patient safety.

IDENTIFYING SPECIFIC DRIVERS OF PHYSICIAN AND ADVANCED PRACTICE PROVIDER BURNOUT ACROSS DIVISIONS IN A DEPARTMENT OF INTERNAL MEDICINE

Elisha L. Brownfield; Benjamin Kalivas. MUSC, Charleston, SC. (Control ID #3183979)

BACKGROUND: Burnout in physicians is well described and has consistently been shown to negatively impact the quality of care delivered, provider productivity and frequency of medical errors. The factors that contribute to burnout are numerous and their specific impact on providers can vary. Reducing burnout and in turn improving provider engagement are vital tasks of any division, department and health care system. Shanafelt et al. have laid out a structured approach identifying nine areas as drivers of burnout and deterrents of engagement. It is unclear how these drivers affect providers from different subspecialties across large departments.

METHODS: The Department of Medicine at a medium-sized academic health system administered the Maslach Burnout Inventory and Areas of Worklife survey and determined that a more detailed assessment of specific factors contributing to burnout was necessary. Using the framework laid out by Shanefelt et al., a focus group of departmental leaders created a survey and distributed this to 261 physician and advanced practice providers in the department. Likert scale assessment of 14 potential burnout drivers, as well as opportunity for free-text comments were included. Results were analyzed by division and compared across the department. Free text answers were independently reviewed by two team members for theme extraction and differences adjudicated.

RESULTS: The survey was completed in 2018 by 124/261 (47.5%) eligible Department of Medicine providers. Among burnout drivers, productivity pressure and not being heard by leadership were consistently rated as "moderately-highly" contributing to burnout across all 9 divisions of the department. Following these top two concerns, there was greater heterogeneity in factors contributing to burnout between different divisions. The free-text comments were analyzed and used to create other potential action items.

CONCLUSIONS: The growing problem of physician burnout must be addressed at all levels of health care. In a recent systematic review, organization-directed interventions were associated with greater effectiveness at reducing burnout than those directed at individuals. There is limited literature supporting specific strategies at a departmental level. Internal medicine is a diverse field, with a variety of subspecialties, resulting in a wide variation in practice structures and personalities. Although some of the themes are consistent, our study supports the hypothesis that factors contributing to burnout are different between divisions. Undertaking this process has allowed our Department to generate a list of action items to pursue in the interest of mitigating burnout, and we will follow the impact on physician burnout over time.

IMPACT OF A CANCER URGENT CARE CLINIC ON REGIONAL EMERGENCY DEPARTMENT VISITS

Arthur Hong¹; Thomas Froehlich¹; Stephanie Clayton Hobbs¹; Simon Craddock Lee¹; Ethan Halm². ¹University of Texas Southwestern Medical Center, Dallas, TX; ²Univ of TX Southwestern Med Ctr, Dallas, TX. (Control ID #3159926)

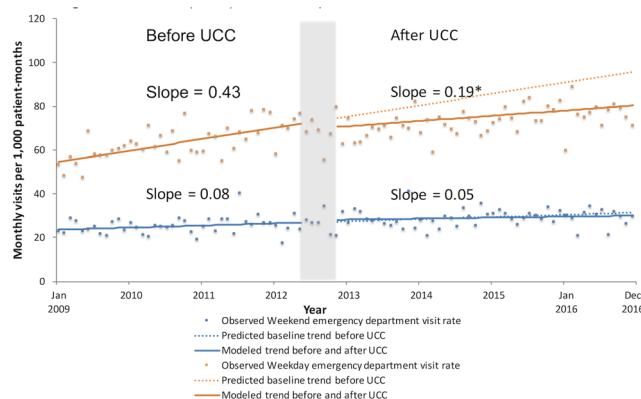

BACKGROUND: Several cancer centers have created urgent care clinics (UCC) to address commonly anticipated issues that arise for adults with newly-diagnosed cancer. There is little rigorous evaluation of whether UCCs reduce emergency department (ED) visits, or serve as conduits to the ED. Interest in reducing early expenditures for cancer patients is spurred by the Oncology Care Model payment demonstration project from Centers for Medicare and Medicaid Innovation. Our institution's oncology practice created a UCC in May 2012, open from M-F, 8AM-5PM.

METHODS: Interrupted time series analysis of regional ED visits generated within 180 days after a diagnosis of cancer. We linked cancer registry patients to a regional database of 98% of non-federal hospitals, to quantify near-comprehensive ED and hospital use. We estimated adjusted monthly ED visit rates, with a denominator of patient-months to account for patient deaths within the 180-day period. We used a 6-month intervention phase-in (May-Oct 2012). We compared weekday ED visits to control weekend ED visits when the UCC was closed.

RESULTS: We identified 33,316 adults ages 18+, contributing 17,835 ED visits within 180 days after cancer diagnosis, between January 1, 2009 and December 31, 2016. Median age was 60 years; 47.2% were female, 65.2% were non-Hispanic white, and 19.1% had advanced-stage cancer at the time of diagnosis. The monthly weekday ED visit rate was growing at 0.43 visits per 1,000 patient-months (95% CI: 0.29, 0.57) prior to the UCC, then fell to 0.19 (95% CI: 0.11, 0.28) afterwards ($p=0.007$). Monthly weekend ED visit rate growth was initially 0.08 (95% CI: -0.03, 0.19) and was unchanged after the UCC, at 0.05 (95% CI: -0.02, 0.13; $p=0.533$). By December 2016, this amounted to a difference of 15.34 fewer weekday ED visits than predicted by pre-UCC trends (95% CI: 4.78, 25.91). One out of every eight patients who visited the ED also visited the UCC.

CONCLUSIONS: Creation of an UCC was associated with a halving of the adjusted growth rate of ED visits, with no change in non-targeted ED visits. However fewer than 1 in 8 patients who visited the ED also used the UCC. This promising finding, despite use by only a limited proportion of patients, suggests the potential for further reductions in ED use.

Monthly emergency department visit rates before and after creation of an urgent care clinic (UCC) for cancer patients

IMPACT OF A STATE OPIOID PRESCRIBING LIMIT AND ELECTRONIC MEDICAL RECORD ALERT ON ACUTE OPIOID PRESCRIPTIONS: A DIFFERENCE-IN-DIFFERENCES ANALYSIS

Margaret Lowenstein^{1, 2}; Erik Hossain³; Wei Yang¹; David Grande^{1, 4}; Jeanmarie Perrone¹; Mark D. Neuman¹; Michael Ashburn¹; M. Kit Delgado^{1, 1}. ¹Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; ²C. Michael J. Crescenz VA Medical Center, Philadelphia, PA; ³Penn Medicine, Philadelphia, PA; ⁴Leonard Davis Institute of Health Economics, Philadelphia, PA. (Control ID #3155039)

BACKGROUND: One strategy thought to prevent chronic opioid use and misuse is judicious opioid prescribing for acute pain. Over half of US states have passed legislation limiting the duration of new opioid prescriptions for acute pain, but there is limited evidence about the impact of these policies. In May 2017, New Jersey enacted a required five-day limit on new opioid prescriptions. In response to the law, the University of Pennsylvania Health System (UPHS) also implemented a non-mandatory electronic medical record (EMR) alert in NJ to notify providers if prescriptions did not meet the five-day requirement. Our aim was to understand the impact of the policy and EMR alert on characteristics of new opioid prescriptions and potential unintended consequences.

METHODS: We evaluated changes in prescription characteristics for initial opioid prescriptions written for adults in UPHS ambulatory practices in both NJ and PA from one year prior to the implementation of the NJ prescribing limit (5/15/16-5/15/17) through 10 months after (5/16/17-3/15/18) using EMR data (Epic Systems). We excluded prescriptions for patients with cancer or enrolled in hospice or palliative care. The primary outcome was change in morphine milligram equivalent (MME) for new opioid prescriptions following the implementation of the law plus EMR alert. We also examined tablet quantity/initial prescription, refills within 30 days, utilization (clinic, ED, inpatient visits) and communication (telephone encounters) for these periods. We performed a difference-in-differences analysis comparing outcomes in NJ practices with control practices in PA, adjusted for patient and clinic characteristics and clustering by provider.

RESULTS: There were a total of 668 new prescriptions in NJ and 4368 in PA. Prior to the intervention, median MME/prescription was 225 mg in NJ and 150 mg in PA, and median quantity was 30 tablets in both states. After implementation, median MME in both states was 150 mg, and median quantity was 20 in NJ and 30 in PA. After adjustment for patient and

practice characteristics, there was a greater decrease in both mean MME and tablet quantity in NJ relative to PA after implementation of the policy plus alert (-82.99 MME/prescription, 95% CI -148.15 to -17.84 and -10.41 tabs/prescription, 95% CI -19.70 to -1.13). There were no significant differences for change in refills, telephone calls, ambulatory or emergency department visits, or admissions based on exposure to the policy and alert.

CONCLUSIONS: Implementation of a state prescribing limit accompanied by an EMR alert was associated with a 30% greater decrease in volume of opioids per new prescription in NJ compared to controls in PA without changes to rates of refills, calls, or visits. The combination of prescribing limit policies and EMR alerts may be an effective strategy to influence prescriber behavior. Further evaluation will be needed to evaluate the impact on downstream outcomes.

IMPACT OF AN INTEGRATED CLINICAL PREDICTION RULE ON ANTIBIOTIC PRESCRIPTION RATES FOR ACUTE RESPIRATORY INFECTIONS IN DIVERSE PRIMARY CARE SETTINGS.

Devin M. Mann¹; Rachel Hess⁵; Thomas McGinn²; Simon Jones¹; Joseph Palmisano³; Safiya Richardson²; Sara K. Chokshi¹; Catherine Dinh-Le¹; Linda S. Park⁴; Rebecca G. Mishuris³; Paul Smith⁴; Ainsley Huffman⁵; Sundas Khan²; David Feldstein⁴. ¹NYU School of Medicine, New York, NY; ²Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; ³Boston University School of Medicine, Boston, MA; ⁴University of Wisconsin School of Medicine and Public Health, Madison, WI; ⁵University of Utah School of Medicine, Salt Lake City, UT. (Control ID #3185043)

BACKGROUND: Clinical decision support (CDS) tools which incorporate clinical prediction rules (CPRs) have the potential to successfully deliver accurate information and guide decision-making at the point of care. Our previously validated integrated clinical prediction rule (iCPR) was designed to guide evidence-based treatment within an electronic health record for streptococcal pharyngitis and pneumonia based on chief complaints of sore throat, cough or upper respiratory infection. In initial testing at a single site, it resulted in high provider tool adoption (58%) and decreased antibiotic prescribing rates (35%) for acute respiratory infections. Our objective for this study was to assess the impact of this tool when adapted and implemented in diverse primary care settings.

METHODS: This was a randomized controlled trial including 33 primary care practices at two large academic health systems in Wisconsin and Utah. Between October 2015 and June 2018 providers in the intervention group were prompted to complete either Centor Score or Heckerling Rule for Pneumonia based on the chief complaint of the patient encounter. EHR data on provider and patient demographics, tool use rates, and antibiotic order rates from 541 providers and 100,573 monitored patient encounters were collected for analysis. Risk ratios, CIs, and P values are calculated from a generalized estimating equation log-binomial model adjusting for clustering of orders or visits by provider and using robust standard error estimators.

RESULTS: The tool was triggered 42,126 times among 214 intervention providers and was completed in 6.9% of eligible visits. The intervention and control groups prescribed antibiotics in 35% and 36% of visits respectively and were not significantly different. There were no differences in rates for rapid streptococcal test or chest x-ray orders between groups (Strep: relative risk, 1.0; P=.11; Pneumonia: relative risk, 1.8; P=.64).

CONCLUSIONS: In diverse primary care settings, the tool was not effective at reducing unnecessary antibiotic prescription and diagnostic testing. This outcome was possibly driven by low overall use of CDS tools highlighting the growing impact of "alert fatigue" and the need for

new approaches to enhance provider engagement with CDS tools. New strategies for reducing the persistently high rates of inappropriate antibiotic prescribing for acute respiratory infections are needed. Novel approaches in future studies are necessary for reducing barriers to CDS tools in order to increase use and engagement.

IMPACT OF COGNITION ON ILLNESS BELIEFS IN BREAST CANCER

Kimberly A. Muellers¹; Karisma Pantaleon¹; Yael T. Harris²; Mita S. Goel³; Jenny J. Lin¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Northwell Health, Great Neck, NY; ³Northwestern University, Chicago, IL. (Control ID #3185328)

BACKGROUND: Older breast cancer (BC) survivors with diabetes (DM) are at higher risk for cognitive dysfunction as age, DM and cancer treatment are independently associated with worse cognitive function. Cognitive dysfunction may also affect survivors' beliefs about both cancer and comorbid illness, with consequences for disease management. We undertook this study to assess the relationship between cognitive function and beliefs about DM and BC among older BC survivors.

METHODS: We enrolled women >55 years with pre-existing DM who had completed first line chemotherapy or are taking hormone therapy for early-stage (I-IIIA) BC diagnosed in the past 5 years. Cognitive function was measured using the Weschler Memory Scale Logical Memory test to assess working memory and delayed recall and the Weschler Adult Intelligence Scale-IV Similarities test to assess executive function. Poor cognition was defined as scoring <1 standard deviation below the mean. Beliefs about DM and BC were assessed using the Illness Beliefs Questionnaire-Revised. DM medications beliefs were assessed using the Beliefs about Medications Questionnaire. Univariate analyses compared differences in cognition by age, race, ethnicity, education, income, and English ability. Mann-Whitney U tests were used to analyze associations between cognition and illness and medication beliefs.

RESULTS: To date, we have enrolled 51 BC survivors. Mean age was 66.5 years; 29% were White, 31% were Black, 8% were Asian, and 18% were Hispanic. Survivors who identified as Asian or "other" race were more likely to have worse working memory ($p=0.013$) and delayed recall ($p=0.042$), and those who were Hispanic ($p=0.009$), had <high school education ($p=0.004$) or household income <\$2,000 per month ($p=0.003$) had poorer executive function. Those with poor working memory perceived both DM and cancer as more cyclical in nature (DM: $p=0.01$; BC: $p=0.021$) and more emotionally impactful (DM: $p=0.038$; BC: $p=0.026$). Additionally, poor working memory was associated with belief in less personal control over DM ($p=0.028$), more consequences of DM ($p=0.05$), and more concern about DM medications ($p=0.01$). Poorer executive function was associated with belief in more cyclical nature of DM ($p=0.038$) and BC ($p=0.04$), as well as less perceived personal control ($p=0.038$) and treatment control ($p=0.035$) for DM but not BC.

CONCLUSIONS: BC survivors with poor working memory and executive function tend to perceive both BC and DM as unpredictable and recurrent and as having more emotional impact. Poor cognition was also associated with other negative beliefs about DM but not BC. Memory and executive function are important for managing medication regimens and other aspects of both DM and BC care; however, DM self-management may pose a higher cognitive load than BC. Understanding the impact of illness beliefs on self-management behaviors will be important for the design of interventions to improve care of survivors with comorbidities.

IMPACT OF FREMANEZUMAB ON HEADACHE-RELATED DISABILITY AND QUALITY OF LIFE IN PATIENTS WITH MIGRAINE

Richard B. Lipton¹; Sanjay K. Gandhi²; Joshua M. Cohen²; Ronghua Yang²; Melissa Grozinski-Wolff²; Xiaoping Ning²; Sissy Easo-Joseph²;

Carolina Burgos-Vega². ¹Albert Einstein College of Medicine, Bronx, NY; ²Teva Pharmaceuticals, Frazer, PA. (Control ID #3185595)

BACKGROUND: Migraine is commonly seen in primary care settings and is the second-leading cause of years lived with disability worldwide. Migraine negatively affects patients' quality of life (QoL), has a broader impact on the family, and is a financial burden on society. Patients with chronic migraine (CM) have 15 headache days/month, 8 of which are migraine days. Patients with episodic migraine (EM) have <15 headache days/month. Preventive migraine treatment is recommended in patients with 4 headache days/month with some impairment. Fremanezumab is a fully humanized monoclonal antibody (IgG2 a) that selectively targets calcitonin gene-related peptide (CGRP) and has been shown in clinical trials to reduce the frequency, severity, and duration of headaches in patients with CM; it is approved for the preventive treatment of migraine in adults. This analysis assessed the impact of fremanezumab on headache-related disability and QoL in patients with migraine.

METHODS: HALO CM and HALO EM were concurrent, multicenter, randomized, double-blind, placebo-controlled, parallel-group Phase 3 studies evaluating the efficacy and safety of fremanezumab for the preventive treatment of migraine. Adults with CM or EM, confirmed during a 28-day pre-treatment period, were randomized to receive either subcutaneous fremanezumab quarterly (675 mg at baseline and placebo at Weeks 4 and 8), fremanezumab monthly (CM: 675 mg at baseline, and 225 mg at Weeks 4 and 8; EM: 225 mg at baseline and Weeks 4 and 8), or placebo over a 12-week period. Headache-related disability was assessed via the six-item Headache Impact Test (HIT-6; score range 36-78) in CM and the Migraine Disability Assessment (MIDAS) questionnaire (score range 0-270) in EM, with higher scores for either indicating greater disability. The Migraine-Specific Quality of Life (MSQoL) was used to assess how migraine affect daily functioning across three domains (range: 0-100; higher scores indicate better QoL): role function-restrictive (RFR), activity limits; role function-preventive (RFP), activity prevention; emotional function (EF), associated emotions.

RESULTS: In HALO CM, fremanezumab significantly reduced HIT-6 scores from baseline (quarterly [least-squares mean change]: -6.4; monthly: -6.8; both $P<0.001$) compared with placebo (-4.5) and significantly improved MSQoL RFR (quarterly: 20.7; monthly: 21.5; both $P<0.0001$ vs placebo: 14.7), RFP (quarterly: 16.8; monthly: 16.5; both $P<0.001$ vs placebo: 12.2), and EF (quarterly: 21.1; monthly: 20.9; both $P<0.05$ vs placebo: 17.0). In HALO EM, fremanezumab significantly reduced MIDAS scores from baseline (quarterly: -23.0; monthly: -24.6; both $P<0.01$) compared with placebo (-17.5). Significant improvements were seen in MSQoL RFR (quarterly: 20.6; monthly: 23.6; both $P<0.01$ vs placebo: 16.5), RFP (quarterly: 17.4; monthly: 18.9; both $P<0.001$ vs placebo: 13.8), and EF (quarterly: 21.8; monthly: 24.6, $P<0.0001$ vs placebo: 19.2).

CONCLUSIONS: Fremanezumab improved disability and QoL in patients with migraine.

IMPACT OF HIGH-DEDUCTIBLE HEALTH PLANS ON HIGH-ACUTITY CARE AMONG PEOPLE WITH BIPOLAR DISORDER

James F. Wharam²; Alisa Busch³; Jeanne Madden⁴; Fang Zhang²; Robert F. LeCates²; Phyllis Foxworth¹; Jamie Wallace²; Stephen B. Soumerai²; Dennis Ross-Degnan²; Christine Lu². ¹Depression and Bipolar Support Alliance, Chicago, IL; ²Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; ³Harvard Medical School and McLean Hospital, Boston, MA; ⁴Northeastern University, Boston, MA. (Control ID #3184516)

BACKGROUND: High-deductible health plans (HDHP) have recently become the predominant commercial health insurance product in the US. People with serious mental illness may be especially vulnerable to adverse outcomes under HDHPs but effects on high-acuity care among such populations are unknown.

METHODS: We studied administrative claims data from a large national health insurer. We used a controlled interrupted-time-series design to examine employer-mandated transitions to HDHPs, minimizing selection bias. The intervention group comprised HDHP members with bipolar disorder age 12-64 included on a rolling basis between 2004-2014. HDHP members were enrolled for 1 year in a low-deductible (\$500) plan followed by 1 year in a HDHP (\$1000). HDHP members were matched to contemporaneous individuals with bipolar disorder in low-deductible plans during both years based on multiple characteristics and using coarsened exact matching. Outcome measures included emergency department visits and hospitalizations for mental health and non-mental health diagnoses. We plotted monthly outcomes for the HDHP and control group to determine whether baseline trends were parallel, and we used difference-in-differences analysis with generalized estimating equations to estimate relative changes in the HDHP group, adjusting for multiple patient characteristics.

RESULTS: Our final sample included 3,264 HDHP members with bipolar disorder and 35,122 matched controls who stayed in low deductible plans throughout. Members who transitioned into HDHPs experienced a -9.1% (95% confidence interval [CI]: -17.7%, -0.4%) pre-to-post reduction in non-mental health emergency department visits relative to controls, and a non-significant 3.0% change (95% CI: -22.8%, 28.9%) in mental health-related emergency department visits. Estimated changes in non-mental health- and mental health-related hospitalizations among HDHP members were not statistically significant: 4.8% (95% CI: -14.1%, 23.7%) and -13.8% (95% CI: -32.1%, 4.4%), respectively.

CONCLUSIONS: People with bipolar disorder who were enrolled in HDHPs experienced reduced emergency department visits for non-mental health conditions but no statistically significant changes in mental health-related emergency department visits or hospitalizations of either type. Patients who suddenly face the high out-of-pocket costs of HDHPs may continue to prioritize acute care in the event of a mental health crisis. Changes in non-mental health emergency department visits raise the possibility that either members inappropriately reduce such care or that they identify more affordable alternatives to emergency department care. Policy makers, employers, and health insurers should remain cautious in encouraging HDHP uptake among people with serious mental illness.

IMPACT OF HIGH-DEDUCTIBLE INSURANCE ON BREAST CANCER CARE AMONG RURAL WOMEN

James F. Wharam¹; Jamie Wallace¹; Fang Zhang¹; Anita Wagner¹; Christine Lu¹; Larissa Nekhlyudov²; Craig C. Earle³; Stephen B. Soumerai¹; Dennis Ross-Degnan¹. ¹Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; ²Dana Farber Cancer Institute, Boston, MA; ³Institute for Clinical Evaluative Sciences, Toronto, ON, Canada. (Control ID #3184500)

BACKGROUND: High-deductible health plans are increasingly common but are associated with breast cancer care delays of up to 7 months among average commercially-insured women. High cost sharing might represent an especially large barrier to care among rural women who generally have challenging access to health care services and lower incomes. We hypothesized that rural women in high-deductible plans, when compared to rural women in more generous plans, would experience substantial delays in breast cancer services.

METHODS: We used 2004-2014 data from a large US health insurer and a before-after controlled time-to-event analytic approach. We applied the Rural-Urban Commuting Area Codes classification to identify women living in rural areas (codes 4 through 9). We included 32,105 rural women in high-deductible plans age 25-64 without evidence of breast cancer prior to the baseline period. These women were continuously enrolled for 1 baseline year in a low-deductible (\$500) plan followed by up to 4 years in a high-deductible (\$1000) plan after an employer-mandated switch. The comparison group included 254,022 contemporaneous rural women whose employers offered only low-deductible plans and who were closely matched

on baseline characteristics. Measures were times to first diagnostic breast imaging, first breast biopsy, incident early-stage breast cancer diagnosis, and first breast cancer chemotherapy. We estimated delays in care in the high-deductible and control groups at baseline and follow-up using a parametric regression survival time model with a Weibull distribution, adjusting for baseline characteristics.

RESULTS: We detected no differences in the timing of breast cancer care at baseline when both study groups had low-deductible plans. During follow-up, the delay among rural high-deductible members compared to rural low-deductible members was 1.6 months ($p < 0.01$) for receiving first breast diagnostic imaging, 3.0 months ($p < 0.05$) for undergoing first breast biopsy, 8.1 months ($p < 0.05$) to incident breast cancer diagnosis, and 10.0 months ($p < 0.05$) to breast cancer chemotherapy initiation.

CONCLUSIONS: Rural women who were switched to high-deductible insurance experienced substantial delays in diagnostic breast imaging, breast biopsy, early-stage breast cancer diagnosis, and chemotherapy initiation compared to rural women in low-deductible plans. Health insurers, primary care physicians, oncologists, and population health managers should carefully monitor breast cancer care among rural women enrolled in high-deductible health plans. Strategies such as value-based insurance and targeted outreach might be needed to prevent adverse outcomes.

IMPACT OF INTERIM BUPRENORPHINE PRESCRIBING ON DISCHARGE FROM INPATIENT DETOX ON HOSPITAL READMISSIONS

Cynthia Eleanya¹; Darius Rastegar²; Megan Buresh¹. ¹Johns Hopkins Bayview Medical Center, Baltimore, MD; ²Johns Hopkins University, Baltimore, MD. (Control ID #3183854)

BACKGROUND: Maintenance treatment with buprenorphine has been shown to be an effective treatment for opioid use disorder (OUD), but the majority of Americans with OUD are not in treatment. Inpatient hospitalization provides an opportunity to identify patients with OUD and start them on treatment. The objective of this study was to determine if providing patients with a prescription for buprenorphine after discharge from inpatient treatment for withdrawal is associated with a decrease in 30 day hospital admissions and to determine factors associated with frequent hospital admissions.

METHODS: All patients admitted for inpatient withdrawal treatment at Johns Hopkins Bayview from October 2016 to December 2017, and discharged with a new script for buprenorphine were included. Wilcoxon Rank Sum was used to compare change in number of patients with pre vs. post intervention 30 day hospital admission. Student's T-test was used to compare pre vs. post intervention 30-day hospital admission rates.

RESULTS: A total of 57 patients received a new buprenorphine prescription during study period. 55 patients (96.5%) had a hospital admission prior to their current admission and 14 (24%) patients had a hospital admission in the 30 days after their current admission ($P < 0.001$). 30-day hospital admission rate was 1.54% prior to the current admission and 0.51% after the current admission ($p < 0.001$).

CONCLUSIONS: Initiating buprenorphine prescription for patients with opioid use disorder after inpatient withdrawal treatment is associated with a significant decrease in 30-day hospital readmissions.

IMPACT OF MEDICAL HOME IMPLEMENTATION ON MISSED TEST RESULTS FOR DIAGNOSTIC EVALUATION OF CANCER

Debra Choi¹; Ashley N. Meyer¹; Li Wei¹; Daniel R. Murphy¹; Hardeep Singh². ¹Baylor College of Medicine, Houston, TX; ²Michael E. DeBakey Veterans Affairs Medical Center and Baylor College of Medicine, Houston, TX. (Control ID #3178465)

BACKGROUND: Lack of timely follow-up of test results can lead to delays in cancer diagnosis. We previously identified certain results to be high-risk for delays: positive fecal occult blood tests/fecal immunochemical tests

(FOBT/FIT) and iron-deficiency anemia (IDA) for colorectal cancer (CRC); elevated serum alpha-fetoprotein (AFP) for hepatocellular carcinoma (HCC); and abnormal chest imaging for lung cancer. The VA implemented the patient-centered medical home (PCMH) model in 2010-2011 to provide patient-driven, team-based care. We hypothesized that PCMH will improve timely follow up of abnormal test results nationally across the VA.

METHODS: To identify patients with potentially missed follow-up, we applied previously validated electronic trigger algorithms to the VA's national repository of electronic health record data. The triggers included patients with newly abnormal results, excluding patients for whom follow-up was not required or was completed within a recommended timeline. Positive predictive values were previously determined to be 56%, 55%, 82% and 61% for FOBT/FIT, IDA, AFP and chest imaging, respectively, and were higher than any known measures of diagnostic care gaps. Positive triggers acted as proxies for missed test results. We applied each trigger to all patients seen at 130 VA facilities across 18 national VA networks from 2006-2015 and derived yearly counts of trigger-positive patients at each network and site. Negative binomial regression models were applied to assess overall and yearly changes in number of trigger-positive patients while accounting for clustering by VA network, over-dispersion and correlation due to repeated measures. Final models were adjusted for VA networks and PCP visits.

RESULTS: After excluding patients not meeting inclusion criteria, we identified 5,887,006 patients from 2006-2015 with + FOBT/FIT, of which 713,035 (12%) met trigger criteria (i.e. potentially missed). Of 37,762,419 patients with IDA, 424,740 (1%) met trigger criteria. Similarly, 888,033 patients received AFP tests, with 78,277 (9%) patients meeting trigger criteria. An estimate of 10,947,742 patients received chest imaging exams, with 291,250 (3%) meeting trigger criteria. The trigger positive mean proportion of potentially missed test results following PCMH implementation decreased for FOBT/FIT (37.7% pre-PACT vs. 35.8% post-PACT) and AFP tests (23.5% pre- vs. 21.1% post), but increased for IDA (33.6% pre vs. 35.1% post) and lung imaging (35.9% pre vs. 38.3% post) tests (all p values<0.001). The mean proportion of potentially missed test results overall was statistically unchanged (32.7% pre-PACT vs. 32.6% post-PACT implementation).

CONCLUSIONS: Primary care medical home implementation does not appear to improve follow-up of abnormal test results that warrant cancer evaluation. Further contextual evaluation to explore lack of impact from this teamwork-based intervention is needed.

IMPACT OF MEDICAL SCRIBES ON CLINICAL PRODUCTIVITY IN ACADEMIC PRIMARY CARE

Anastasia Pozdnyakova; Neda Laiteerapong; Sandra Ham; Wei Wei Lee, University of Chicago, Chicago, IL. (Control ID #3186237)

BACKGROUND: Primary care practices have been increasingly hiring medical scribes to assist with Electronic Health Record (EHR) documentation and to address physician burnout. However, little is known about the impact of scribes on productivity in primary care. The aim was to assess the impact of scribes on clinical productivity at an academic general internal medicine clinic.

METHODS: We piloted a 3-month scribe program at an academic general internal medicine clinic with six faculty and one full-time professional medical scribe. The scribe was present during 25-80% of total clinic sessions for each provider. The scribe drafted EHR notes for providers to review and sign. All clinic sessions for 2 months prior (baseline control) and during the 3-month pilot (without scribe (concurrent control) and without scribe (intervention) were included. The main outcome was the number of patients seen per clinic session. Secondary outcomes were rates of reconciliation of external information; review of problem list, medications, and immunizations; and patient time to check-out. Interrupted time series mixed models were used to test the scribe effect, controlling for weekday, AM/PM clinic session, and provider. We compared results for the baseline, concurrent control, and intervention groups.

RESULTS: The baseline period included 789 encounters; the pilot had 1,184 encounters, 579 (48.9%) without scribe and 605 (51.1%) with scribe. At baseline, providers saw an average of 6.85 patients per clinic session (95% CI 6.27-7.48). With the scribe, this number increased non-significantly to 7.26 patients per clinic (CI 6.99-7.53, p=0.07). Rates of reconciliation of external information and review of the problem list were higher with the scribe than at baseline (77.0% (CI 65.8-85.3%) vs. 68.8% (CI 56.8%-78.7%), p=0.002 and 9.42% (CI 5.48%-15.7%) vs. 6.10% (CI 3.11%-11.7%), p<0.0001, respectively). The percentage of encounters billed as a Level 4 or 5 Professional Fee Service increased from 91.0% (CI=84.6%-94.9%) at baseline to 95.3% (CI 91.4%-97.5%, p=0.005) without the scribe and 93.4% (CI 88.8%-96.2%, p=0.003) with the scribe. The time to check-out declined non-significantly from 76.8 (CI=59.6-107.8) minutes at baseline to 70.1 (CI=58.7-86.8) minutes without the scribe and 66.4 (CI=60.2-74.1) minutes with the scribe. There were no differences for review of current medications or immunizations.

CONCLUSIONS: In this short pilot, we found evidence of more detailed review of patient charts, particularly for the problem list and reconciliation of external information. The number of patients seen per clinic session with a scribe and time to check-out suggested improvements but were not significant. These findings suggest that hiring scribes may improve productivity and documentation of care in the primary care setting; however, further research is needed.

IMPACT OF RELIGION ON MEDICAL STUDENT PERCEPTIONS AND INTENTION TOWARDS ABORTION

Joseph S. Needleman¹; Shenila B. Lallani²; Cynthia H. Chuang¹. ¹Penn State College of Medicine, Hershey, PA; ²University of Alabama School of Medicine, Birmingham, AL. (Control ID #3186077)

BACKGROUND: One in four U.S. women have an abortion during their lifetime, however 90% of U.S. counties currently do not have an abortion provider. The future of abortion care relies on a physician workforce who plans to incorporate abortion into their medical practice. This study was designed to describe medical student attitudes toward abortion and abortion provision. Religious affiliation influences attitudes toward abortion among the general public, but whether religious affiliation and religiosity is associated with abortion attitudes and practice intentions among future physicians is unknown.

METHODS: Students at the University of Alabama School of Medicine, Penn State College of Medicine, and University of Massachusetts Medical School were distributed a 26-item electronic survey designed to measure abortion attitudes, practice intentions, religious beliefs, and demographics. The main independent variable was whether religion was very important in the student's life. Logistic regressions were used to model three outcomes: 1) the belief that abortion should be legal in all/most cases, 2) career plan to incorporate abortion into practice, and 3) willingness to refer patients seeking abortion. Models controlled for religious affiliation, gender, intended specialty, intention to practice in a rural location, a rural childhood residence, in-state status, and year in school.

RESULTS: Of the 862 students who completed the survey (response rate 46%), 35% said religion was very important in their lives. The study sample was 31% Protestant, 16% Catholic, 3% Jewish, 12% other religion, and 37% had no religious affiliation. Sixty-four percent agreed that abortion should be legal in most or all cases, 25% intend to incorporate medical and/or surgical abortion into their practice, and 86% would refer patients to other providers for abortion services. In the multivariable models, religion being very important in a student's life was a strong negative predictor of all 3 outcomes; those students were significantly less likely believe abortion should be legal in all/most cases (AOR 0.17, 95% CI 0.11-0.25), plan to incorporate abortion into their practice (AOR 0.24, 95% CI 0.14-0.42), or be willing to refer patients for abortion (AOR 0.10, 95% CI 0.05-0.20). Catholic affiliation and male gender were also negative predictors of all 3 outcomes.

CONCLUSIONS: Like the general public, the majority of medical students in our study said abortion should be legal in most or all cases. However, abortion attitudes were strongly associated with religiosity, religious affiliation, and gender, suggesting that personal beliefs, values, and experiences strongly influence abortion attitudes. Controversial topics in medicine are often avoided in medical student curricula, but we would encourage such topics be addressed openly and scientifically so student have the opportunity to reassess their attitudes in the context of medical evidence and patient experience.

IMPACT OF WORKPLACE WELLNESS ON HEALTH AND ECONOMIC OUTCOMES: A RANDOMIZED CONTROLLED TRIAL

Zirui Song^{1, 2}; Katherine Baicker^{3, 4}. ¹Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³University of Chicago, Chicago, IL; ⁴National Bureau of Economic Research, Cambridge, MA. (Control ID #3186066)

BACKGROUND: Employers are increasingly investing in workplace wellness programs to improve employee health and decrease health care costs. However, little experimental evidence on the effects of such programs exists, particularly workplace-wide interventions that affect culture or norms. We examined the effect of a multi-component workplace wellness program, similar to wellness programs offered by employers in the U.S., using a randomized controlled trial.

METHODS: This randomized controlled trial spanned January 2015 through June 2016. We used random assignment at the worksite level to assess the effects both of working at an intervention worksite (intention-to-treat) and of participating in the programming (local average treatment effect). The wellness program was implemented at 20 randomly-selected treatment worksites (4,037 employees) and 140 randomly-selected control worksites (28,936 employees) at a large multi-site warehouse retail company. The program comprised 8 modules focused on areas of wellness including nutrition, physical activity, and stress reduction, with program implementation carried out by Registered Dietitians. We examined 4 pre-specified domains of outcomes: (1) self-reported health and behaviors; (2) clinical measures of health; (3) health care spending and utilization; and (4) employment outcomes. We assessed the heterogeneity of program effects by age and sex. We also conducted secondary analyses, including using a pre-specified cohort of stably-employed workers, worksite-level analyses, and alterations in the statistical model. We assessed endogenous selection into program participation and into primary data collection.

RESULTS: There were 4,037 individuals at treatment worksites, 4,106 at primary control worksites (which received surveys and biometrics, but no wellness program), and 24,830 at secondary control worksites (business as usual). About 20% of the population was black and 18% Hispanic; 60% of workers were full-time. After 18 months, the wellness program led to a higher proportion of employees who reported engaging in regular exercise (8.3 percentage-points more, p=0.03) and actively managing their weight (13.6 percentage-points more, p=0.02). These outcomes were 10.6 percentage-points (p=0.02) and 17.2 percentage-points (p=0.02) higher, respectively, for program participants. The program had no significant effects on clinical markers of health; spending or utilization; or absenteeism, tenure, or job performance. We found no evidence of differential selection into survey participation or biometrics between treatment and control on all baseline covariates.

CONCLUSIONS: This randomized controlled trial of a workplace wellness program found significant effects on self-reported health behaviors, but no significant effects on other outcomes after 18 months. Amidst a shortage of causal evidence on workplace wellness programs, these results from a randomized trial may temper the expectations of such programs to improve health or save money in the short term.

IMPACTS OF IMPROVED CONTINUITY OF CARE IN RESIDENT PRIMARY CARE CLINICS ON PATIENT OUTCOMES: A SYSTEMATIC REVIEW

Margaret Connolly¹; Robert J. Fortuna¹; Erin D. Snyder³; William G. Weppner². ¹University of Rochester, Rochester, NY; ²University of Washington, Boise, ID; ³University of Alabama at Birmingham, Birmingham, AL. (Control ID #3186321)

BACKGROUND: Continuity of care has been established as an essential component of non-teaching primary care practices, resulting in improved patient and provider satisfaction, chronic condition management, and adherence with screening recommendations. The influence of continuity in resident practices on quality outcomes remains unclear. The goal of this systematic review is to summarize existing data addressing the effect of continuity of care in resident primary care clinic settings on measurable patient health outcomes.

METHODS: A systematic search was performed through PubMed to identify articles published prior to August 1, 2018 addressing continuity of care in resident primary care clinic settings including internal medicine, pediatrics, internal medicine and pediatrics, obstetrics and gynecology, and family medicine. Abstracts were then evaluated by two independent reviewers and excluded if not meeting strict criteria including English language, original research, focus on a primary care residency program as recognized by the American Council for Graduate Medical Education, and providing a definition and quantitative value for continuity. Through this process, 39 articles were identified as meeting all inclusion criteria and underwent full text review.

RESULTS: This review revealed significant variation in methods, definition of continuity, and endpoints measured in the existing literature. Study participants included an average of 273 residents (range 1-5000), 15 academic attending preceptors (range 4-66), and 13,021 patients (range 40-149,346). Additionally there was significant variability in the duration of time evaluated in each study, ranging from 1 week to 17 years (average 2.3 years). The Usual Provider of Care Measure, defined as an individual patient's percentage of visits with a single provider, was the most frequently used definition of continuity of care. However, this was used in only 49% of included studies. Furthermore, studies measured a variety of outcomes including diabetes and hypertension control, rates of screening colonoscopy and mammography, and emergency department utilization, and patient satisfaction. Results of multiple studies suggest improvement in diabetes control, hypertension control, and adherence to screening recommendations with improved continuity of care. However, these results were inconsistent and varied significantly between studies with multiple studies showing no effect.

CONCLUSIONS: Review of the existing literature revealed that increased continuity of care in resident primary care clinics may improve patient-specific health outcomes, most clearly in diabetes. However, significant differences in study design and outcomes make generalizing results difficult. Additional research is needed to delineate continuity's relationship to chronic medical disease management and utilization in resident clinics.

IMPLEMENTATION OF AN EHR-BASED RISK-STRATIFIED PROSTATE CANCER SCREENING PROGRAM IN A PRIMARY CARE NETWORK

Anand Shah¹; Robert C. Mills²; Devon Check¹; Terry Hyslop²; Thomas Polascik²; Daniel George²; Steven Patierno²; Andrew J. Armstrong²; Michael Ferrandino¹; Glenn M. Preminger¹; Rajan T. Gupta¹; Robert Lee¹; Nadine J. Barrett⁴; John Ragsdale¹; John Anderson³; Kevin Shah³; Kevin Oeffinger². ¹Duke University, Durham, NC; ²Duke Cancer Institute, Durham, NC; ³Duke University Health System, Durham, NC; ⁴Duke University, School of Medicine, Durham, NC. (Control ID #3159942)

BACKGROUND: Prostate cancer screening recommendations and the proportion of men undergoing screening with a prostate specific antigen (PSA) test varies widely across the U.S., due largely to controversies regarding the harms and benefits of screening. As a consequence, screening rates are decreasing while the incidence of advanced stage prostate cancer is increasing, particularly among African American men. A multi-disciplinary group developed an age- and race-specific risk-stratified screening algorithm, combined with shared decision making, and using varying intervals of PSA follow-up testing. Our overarching goals were to identify clinically significant cancer while minimizing treatment of indolent cancer through a standardized practice model.

METHODS: We evaluated the impact of implementing this risk-stratified screening algorithm in February 2017 in the health maintenance section of our health system-wide EHR (electronic health record; Epic). We used a pre-post implementation study design, comparing the percent of men who met up-to-date screening criteria, based on the algorithm, from 2/1/16-2/1/17 (pre-implementation) to 2/2/17-2/21/18 (post-implementation). Men were defined as 'met screening' if they had a PSA value recorded in our EHR within 27 months prior to their visit with their primary care provider (PCP). Descriptive statistics were performed followed by a one-sample pre-post test for binomial proportion and a two- proportion z test.

RESULTS: During the pre- and post-implementation periods, 49,058 and 49,988 men, respectively, aged 40-74 were seen by 290 PCPs across 26 clinics (20.6% African American, pre and post). Overall, the percent of men who met screening criteria based on the algorithm increased from 48.9% (pre) to 67.5% (post) ($p<0.0001$); for African Americans it increased from 54% (pre) to 71.5% (post). The percent of men who met screening criteria increased across all age groups: age 40-45, 17% to 46%; age 45-49, 31% to 55%; age 50-69, 60% to 73.8%; and age 70-74, 51% to 67%. Similarly, the percent of men who met screening criteria increased across all clinic sites and all PCPs. Importantly, while screening according to the algorithm increased, the volume of PSA test ordering did not change. In the pre- and post-implementation period, 27,100 and 27,500 PSAs were ordered, respectively. This stability in PSA volume was largely due to a decrease in annual testing among men in the pre-implementation period.

CONCLUSIONS: With the implementation of an EHR-based risk-stratified algorithm, we observed a significant increase in meeting our screening criteria while avoiding a net increase in PSA test volume. This approach was successful in standardizing our network-wide approach to prostate cancer screening. Future efforts will evaluate costs and downstream outcomes of this strategy.

IMPLEMENTATION OF FOOD INSECURITY SCREENING IN ADULT PRIMARY CARE PATIENTS

Arjun Janardhan; Michael W. Latreille; Charles D. MacLean; Michelle Cangiano; Claudia Berger. The Robert Larmer, MD College of Medicine at the University of Vermont, Burlington, VT. (Control ID #3184866)

BACKGROUND: Social determinants of health (SDH) are increasingly recognized for their importance in driving health outcomes. Food insecurity (FI), a lack of regular access to adequate food, is prevalent in the United States, impacting an estimated 12% of households in 2017. The two-item Hunger Vital Sign (HVS), has demonstrated validity in identifying FI, though there is not agreement on how best to address FI in a healthcare setting. This study aimed to evaluate the implementation of a screening protocol for FI in adult primary care patients, and to investigate any downstream impacts on services delivered in patients who screened positive for FI.

METHODS: In December 2017, our institution added functionality for entering and tracking SDH via an Epic-based EMR. The tool, which incorporated the HVS, was developed based on the Health Related Social Needs Screening Tool by CMS. We instituted protocols for administering and entering the HVS component at two academic primary care sites in Vermont: a semi-urban adult internal medicine practice and a rural family

medicine practice. Implementation plans were developed at both sites, each involving education for providers and staff, and pairing of the HVS with annual behavioral health screening. We then identified patients who screened positive for FI from January 1 through April 30, 2018 and retrospectively analyzed charts for services in place prior to positive screens, as well as for documentation and actions taken in response to positive screens.

RESULTS: A total of 1,188 patients were screened for FI during the study period, and 79 (7%) screened positive. Of patients with FI, 41 (48%) had some documentation of food or financial insecurity prior to screening. A total of 32 (37%) were documented to have prior access to food insecurity services such as food stamps, food bank etc., and 19 (22%) had been previously seen by a social worker embedded in the practice. At the time of positive screen, 26 (31%) provider notes included documentation of FI. In response to a positive screen, 16 patients (19%) were offered social work referral, of whom 12 (14%) completed a visit.

CONCLUSIONS: In this brief pilot study, we found the implementation of a process for FI screening in primary care to be relatively straightforward, made so by pairing it with other annual health screening protocols and the presence of a function for entering SDH in Epic. The HVS screening tool was also successful in newly identifying FI, as evidenced by the absence of prior documentation in nearly half of food insecure patients. However, the paucity of subsequent documentation and the small fraction of patients who received targeted intervention, despite the education for providers and staff at both practices, indicate a need for further investigation around the best approach to addressing FI in a primary care setting, once it is identified.

IMPLICATIONS OF USING AN ALTERNATIVE MEASURE TO ASSESS OPIATE DAYS SUPPLIED AT DISCHARGE

Nicholas Iverson; Nader Najafi; Yumiko Abe-Jones; Kirsten Kangelaris; Margaret Fang; Priya A. Prasad; Catherine Lau. UCSF, San Francisco, CA. (Control ID #3184807)

BACKGROUND: Development of opiate use disorder has been associated with prolonged opiate prescriptions. Conventionally, opiate-days supplied has been calculated by the discharge prescription signature. However, it is not clear whether the number of days supplied reflects the actual needs of the patient. We compared the days supplied using two metrics: one based on the discharge signature, and one adjusted for the amount of opiates required during the hospitalization.

METHODS: We used the electronic health record to identify all patients hospitalized on the acute care medical service at a 600-bed tertiary care hospital from 2012-2018 who received opiates during hospitalization and were discharged on an opiate. We excluded patients with ICD9 or 10 codes for cancer-related pain, sickle cell disease, or who were on hospice or followed by the palliative care service. We ascertained the total amount of opiates administered for each hospital day, standardized to morphine milligram equivalents (MMEs). The number of opiate-days supplied was first determined using the discharge prescription, based on the prescription signature and number of pills ordered. We then determined the number of opiate days supplied adjusted for the amount of opiates required by the patient during the last 24 hours of hospitalization. The difference in days supplied between the two measures was compared using t-tests.

RESULTS: We identified 6,902 patients with a baseline opiate prescription and 2,373 patients without opiates as an admission medication who were discharged on an opiate. The median MME per day of hospitalization was 57.7 mg [IQR 21.1, 150.4], and 60 mg [IQR 24, 165] for the last 24 hours. Using the metric adjusting for the opiate needs on the last 24 hours of hospitalization resulted in a mean days supplied of opiates that was 3.6 days longer than when using a standard days supplied metric (11.9 vs 8.3 days, $p<0.001$). Patients with a baseline opioid prescription were prescribed a median of 10 days on discharge by prescription signature, and 14 days based on hospital requirements ($p<0.001$). Patients without a baseline opioid prescription were prescribed a median of 5 days on discharge by

prescription signature, and 7.1 days based on hospital requirements ($p < 0.001$). Of patients prescribed <7 days of opioids by discharge prescription signature, 126 patients (3.5%) received a >30 day prescription when adjusted for needs in the hospital. A total of 325 patients (8.0%) without a baseline prescription were discharged on opioids despite requiring no opioids in the 24 hours prior to discharge.

CONCLUSIONS: Days on a prescription signature and a calculation of days based on hospital need are two significantly different mechanisms to calculate discharge opioid-days. The amount of opiates supplied to patients at discharge may exceed their actual clinical needs, since the frequency with which a patient takes opiates at home after discharge may be better reflected by the adjusted days model.

IMPLICIT BIAS AMONG HOUSESTAFF IN THE SAFETY NET: INITIAL RESULTS OF A PROSPECTIVE COHORT STUDY

Giulia Leggett¹; Nicholas Nelson¹; Katherine Dang²; Kala Mehta². ¹Highland Hospital, Oakland, CA; ²Highland Hospital, Danville, CA. (Control ID #3165223)

BACKGROUND: Implicit bias is an important contributor to health disparities. While a robust literature describes changes in empathy during medical training, little is known about implicit biases among resident physicians during training. The goal of our study is to assess the prevalence and evolution of implicit bias over the course of graduate medical training in a safety-net hospital serving one of America's most diverse communities.

METHODS: This is a prospective cohort study of resident physicians in a safety net hospital, who participated on a voluntary basis. Participants were assigned personalized codes to ensure anonymity over serial assessments, and given a survey which assessed explicit biases, as well as attitudes towards medical school admissions and racial, financial, and other biases in healthcare. They were then asked to take Implicit Association Tests (IAT) on race and skin tone, and to report their scores anonymously using their personalized code. Fischer exact test and Kruskal-Wallis test were used to analyze whether any difference existed between PGY year with IAT, explicit bias and attitude results.

RESULTS: 17 residents participated. Implicit and explicit bias differed across PGY1 and PGY3 classes with results displayed in Table 1. There was no statistically significant relationship between IAT race categories and resident characteristics.

CONCLUSIONS: Acknowledging the limits of our study, our results suggest the intriguing possibility that implicit bias falls over the course of training within a safety net environment. We plan to evaluate this hypothesis through serial assessment of individual housestaff as they move through residency.

IMPROVED CONTROL OF DIABETES ASSOCIATED WITH A MOBILE TECHNOLOGY INTERVENTION FOR DIABETES MANAGEMENT

Aaron Baum¹; Erick R. Scott¹; Pei Wang¹; Christophe Hunt⁶; John W. Vona⁶; Abby L. Schwartz⁵; Ronald Tamler⁴; Laurie Edelman²; Victoria L. Mayer³; Juan P. Wisnivesky⁴; Michael Berger⁶; Andrew Kasarskis¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Mount Sinai Medical Center, New York, NY; ³Icahn School of Medicine at Mount Sinai, Brooklyn, NY; ⁴Mount Sinai School of Medicine, New York, NY; ⁵The Mount Sinai Medical Center, New York, NY, NY; ⁶Mount Sinai Health System, New York, NY. (Control ID #3185573)

BACKGROUND: Mobile technology tools for diabetes management are of significant clinical and policy interest, as they offer a potentially low-cost and scalable platform for frequent monitoring and tailored engagement of patients with diabetes. We sought to determine whether a mobile technology intervention for diabetes management - comprising an electronic

glucometer device that stores blood glucose data and reports data to patients and their primary care provider, with 24/7 on call alert phone calls from nurses - achieved the objective of reducing glycated hemoglobin among a majority low-income and racial and ethnic minority population.

METHODS: The study population included adult Medicaid beneficiaries with a prior diagnosis of type 2 diabetes who were patients of a large, urban internal medicine primary care practice. We used electronic health records data from the Mount Sinai Data Warehouse from 2013-2017. All patients received usual care that included visits with a certified diabetes educator. Given non-random participation in the intervention, we used a difference-in-difference analysis to compare within-patient changes over time in glycated hemoglobin among patients who enrolled in the intervention versus those who did not enroll, while using fixed effects to control for common time trends and time-invariant individual characteristics, such as age, sex, race/ ethnicity, and baseline health status. <style type="text/css">

RESULTS: 150 and 2,593 individuals met the criteria for the treated and control groups, respectively. The overall study population had a median age of 63.60 years old, was 64.59% female, and had an average baseline glycated hemoglobin of 7.96 percent. Relative to changes over time in the control group, among the treated group glycated hemoglobin was lower by -0.50 percent (95% CI -0.69, -0.31; $p < 0.001$) at 6 months, -0.65 (95% CI -0.92, -0.39; $p < 0.001$) at 12 months, and -0.58 (95% CI -1.20, 0.09; $p = 0.09$) at 18 months. Males benefitted more than females. Estimated coefficients were not significantly different from zero in pre-treatment time periods, providing support for the key identifying assumption of parallel trends. Results were consistent in sensitivity analyses that constructed alternative control groups using coarsened exact matching or used patients who enrolled in the program later as controls for those who enrolled earlier.

CONCLUSIONS: Lower glycated hemoglobin was associated with a mobile technology intervention for diabetes management. An important limitation of this study is that difference-in-differences analyses rely on the untestable assumption that in the absence of the treatment, the difference between treated and the control groups would have been the same after the intervention.

IMPROVEMENT IN ABDOMINAL AORTIC ANEURYSM (AAA) SCREENING IN INTERNAL MEDICINE RESIDENT VETERAN'S ADMINISTRATION CONTINUITY OF CARE CLINIC

Roger D. Struble^{1, 3}; Christopher Koehn^{1, 3}; Iiro Honkanen^{1, 3}; Behnam Laderian^{1, 3}; Noah Williford^{1, 3}; Amanda Heuszel^{1, 3}; Syndey Bowmaster^{1, 3}; Carly Kuehn^{2, 3}; Leslie Brettell³. ¹University of Iowa Hospitals and Clinics, Coralville, IA; ²University of Iowa, Iowa City, IA; ³Iowa City VA Healthsystem, Iowa City, IA. (Control ID #3187015)

BACKGROUND: Description of problem: The USPSTF and American Association for Vascular Surgery recommend one-time screening for AAA with ultrasonography in men ages 65 to 75 years who have ever smoked. In Iowa, 94.2% of a total 226,175 veterans are male and use the VA at a rate higher than the national average, which makes them a high priority target for AAA screening compliance. Objectives: Increase AAA screening compliance to at least 75% of eligible veterans over the course of the 2017-2018 academic year in Internal Medicine Resident Continuity of Care clinic.

METHODS: Interventions: Increase resident provider education on AAA screening recommendations through a presentation at conference and educational emails. Increase patient education regarding AAA and appropriate screening by distributing pamphlets in patient exam rooms at the primary care clinic. Measures: Current or former male smokers between the ages of 65-75 were identified from eight internal medicine patient panels at the Iowa City VA Health Care System. Screening compliance was measured as completed if abdominal duplex ultrasonography or CT scan of the abdomen identifying the aorta were performed for any reason. Data was obtained before and after the six-month quality improvement intervention. Statistical analysis was performed using N-1 chi-squared test using MedCalc statistical software.

RESULTS: Findings: A total of 86 patients were identified pre-intervention with a screening compliance of 66.2%. Post intervention, a total of 70 veterans were identified with a significant increase in screening compliance to 82.9% ($p=0.0188$).

CONCLUSIONS: Key Lessons: The group significantly increased AAA screening compliance after a comprehensive intervention targeting both providers and patients. By providing education to both providers and patients, we allowed for shared decision making, which increased screening rates. The veteran population is largely male with a high prevalence of smokers, making this a high impact intervention. Ultrasonography is the preferred screening test as it is noninvasive, low-cost, without radiation; with high sensitivity (94%), specificity (98%). CT was used in place of ultrasound if previously done as it has a high sensitivity (90%) and specificity (91%) for AAA, and additional ultrasound screening would be wasteful and unlikely beneficial. The USPSTF AAA screening recommendation was published in 2007. As more providers have become familiar with the guidelines, screening rates have increased. In 2012, a study at a large academic private medical center found an effective screening rate of 9.2%. A 2015 study in a primary care VA clinic similar to our population found a screening rate of 30%. Through intervention we were able to reach 82.9%. It will be important to continue to educate both patients and providers to ensure that screening for AAA continues to be maintained at high rate.

IMPROVING BLOOD PRESSURE CONTROL BY OPTIMIZATION OF GUIDELINE DIRECTED THERAPY FOR HYPERTENSION IN A PRIMARY CARE SETTING: QUALITY IMPROVEMENT PROJECT

Cirous Sadeghi; Hassan A. Khan; Alexander J. Tiemeier; Smita Y. Bakhai. University at Buffalo, Buffalo, NY. (Control ID #3167676)

BACKGROUND: Our Internal Medicine Clinic (IMC) is an academic safety-net clinic, with its population comprised of 70% African Americans within an underserved region. It is estimated about 16% of the patients with hypertension (HTN) had BP at goal (less than 130/80 mmHg), according to the 2017 ACC/AHA HTN guidelines. It is estimated 70% of the patients have a diagnosis of HTN with a mean high body mass index (BMI) of 32 in IMC. The aim of this quality improvement (QI) project is to improve BP control to less than 130/80 from a baseline of 16% to 50% over 18 months in patients between 40 to 80 years old.

METHODS: A multidisciplinary QI team performed root cause analysis using fishbone diagram and identified physician, patient and system related barriers to optimal BP control. The QI team included physician champions, nursing and ancillary staff, residents, a social worker, patients; and administrative and information technology staff. We performed 4 Plan-Do-Study-Act (PDSA) cycles. The major components of interventions included: 1) Leveraging health information technology, 2) nursing education on accurate BP measurement, 3) physician education regarding ACC/AHA guidelines and medication reconciliation; and 4) patient education. The outcome measure is the percentage of patients with BP<130/80. The percentage of patients with Stage 1 and Stage 2 HTN; and HTN crisis were also monitored. Process measures included: 1) care guide use for DASH diet and lifestyle modification for patient education, and 2) completion of medication reconciliation. Balanced measures included increase patient wait time due to BP re-check and education; and time constraints for physicians during clinic visit. Data analysis was performed using a monthly run chart.

RESULTS: There was a steady increase and sustainable improvement of patients with BP nearing goal (<130/80) during various PDSA cycles. Sustainable improvement in stage 1 HTN, achieved highest at 41.5% in November 2018. There was also sustainable increase in rates of medication reconciliation and care guide use during clinic visit. Table below represents data from May to November 2018.

CONCLUSIONS: Engagement and synergy of our multidisciplinary team were the key factors for the success of this QI. Future PDSA cycles will

include: 1) assessment of patient's adherence to medications, appointments and identifying barriers for non-adherence, 2) continuous education and reminders to patients and physicians regarding optimal BP goal, and 3) home BP measurements with patient logs to confirm mask and white coat HTN.

IMPROVING COMMUNICATION OF DISCHARGE PLANS AMONGST RESIDENTS, NURSES AND PATIENTS: A QUALITY IMPROVEMENT PROJECT

Camille Hawkins; Arianne Clare C. Agdamag; Manya Gupta. Rush University Medical Center, Chicago, IL. (Control ID #3186779)

BACKGROUND: Discharge of hospitalized patients is a multistep process, involving communication amongst numerous healthcare providers. Delays in discharge cause a backlog of patients in the ED and ICUs, leading to prolonged patient wait times and overcrowding in the ED. Furthermore, many discharges occur in the evening hours, when there is a covering provider. Our institution has no standardized protocol on relaying discharge information from residents to nurses and patients, other than a simple EMR-generated discharge medication list. In this project, our goal was to determine the baseline perception of the discharge process and implement a mandatory, standardized discharge instruction checklist accessible to nurses, residents, and patients.

METHODS: Baseline surveys to determine problems with the discharge process were sent via email to nurses on general medicine floors and to all Internal Medicine residents. A discharge checklist was developed based on the issues identified. The checklist was launched during a resident safety conference, and we worked with our EMR representatives to make sure the list was included in patients' discharge paperwork, which is visible to all physicians, nurses, and patients. Residents were required to complete this checklist prior to printing the AVS.

RESULTS: The survey was completed by 86 nursing staff and 48 residents. For both residents and nurses, >95% have encountered discharge related issues. For nurses, 84.9% found inconsistencies in discharge related documentation, 89.5% have been contacted by patients after discharge and the most common issues were: discharge medication, transportation, and follow-up. Among residents, 91.7% had been contacted by nurses during cross cover to clarify discharge plans, 95.8% were willing to complete a discharge checklist and the most common issues were: medication refills, opioid prescriptions and follow-up. Both nurses (94.2%) and residents (81.3%) agreed that a standardized discharge template would be beneficial.

CONCLUSIONS: The majority of nurses and residents perceive a lack of standardized discharge communication. This ineffective communication can have a significant impact on a patient's health. The discharge related issues seen in the survey, specifically medication related questions, were similar to what have been reported in literature. Prior studies have also identified ineffective communication as the underlying reason for adverse events after discharge. The openness of nursing and residents in the implementation of a standardized checklist is key for improvement. Our checklist includes the reason for admission, medication changes, follow-up and contact person after discharge, all written in patient-friendly language. We hope that our checklist will provide clearer discharge plans for both patients and providers, and ultimately help prevent adverse events. To determine its efficacy, a post-intervention survey is being developed for residents and nurses.

IMPROVING SAFE OPIOID PRESCRIBING IN PRIMARY CARE: IMPACT OF A CLINIC-WIDE POLICY AND DATA DRIVEN PRESCRIBER FEEDBACK ON PRESCRIBING PRACTICE

Trang Vu; Linda Wang; Eva Waite; Caroline Round; Mary Fishman. Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3184607)

BACKGROUND: Despite the development of safe opioid prescribing guidelines, prescription opioids continue to contribute to the opioid epidemic

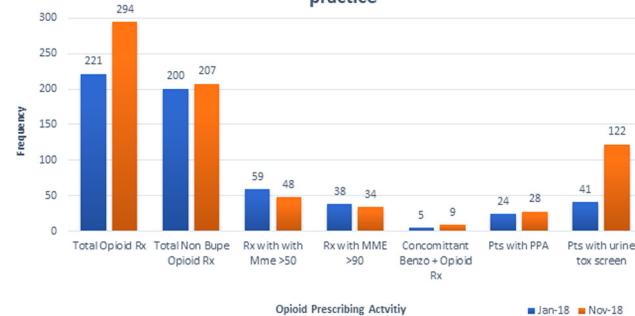

in the US. The Internal Medicine Associates Opioid Management Committee (IMA OMC), a multidisciplinary group of primary care providers and pain management specialists, was formed to promote safer opioid prescribing by primary care providers within an urban hospital-based primary care clinic.

METHODS: In January 2018, the IMA OMC created and disseminated a guideline-based safe opioid prescribing policy, which included obtaining yearly patient-provider agreements (PPA) and routine urine toxicology. The committee also reviewed monthly electronic medical record (EMR) data on opioid and benzodiazepine prescriptions. In March 2018, providers received their individual prescription data electronically, highlighting patients receiving high dose opioid (morphine milligram equivalent, MME >50) or concomitant opioid-benzodiazepine prescriptions. Retrospective data analysis of prescription data from January and November 2018 were completed to observe any changes in opioid prescribing activity.

RESULTS: As compared to January 2018, in November 2018, there was an increase in total number of opioid prescriptions (31.5%). However, after removing buprenorphine prescriptions, the number of non-buprenorphine opioid prescriptions only increased by 3.5%. The average MME decreased from 52.6 to 47.7. Furthermore, the number of patients with MME >50 decreased from 59 to 48, and number of patients with MME >90 decreased from 38 to 34. The number of patients with concomitant opioid-benzodiazepine prescriptions did increase slightly from 5 to 9 patients. The number of patients receiving opioid prescriptions with a PPA recorded in the EMR rose by 16.7%, while the number of patients with at least one urine toxicology screen increased significantly by 197.6%.

CONCLUSIONS: The dissemination of a clinic-wide safe opioid prescribing policy with direct data-driven prescriber feedback was associated with a reduction in high dose opioid prescriptions and increased utilization of PPAs and routine urine toxicology. While the total number of opioid prescriptions increased, the number of patients receiving opioid prescriptions with MME >50 and >90 decreased. This provides promising data on the efficacy of policy and data driven interventions to promote safer opioid prescribing.

Impact of a clinic-wide safe opioid prescribing policy and data driven prescriber feedback on opioid prescribing practice

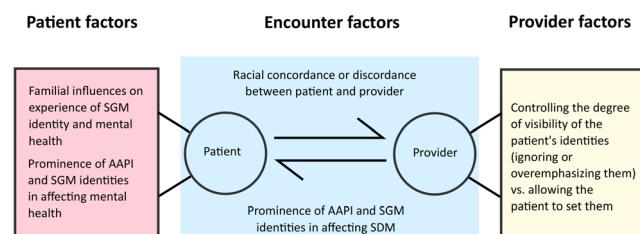

IMPROVING SHARED DECISION MAKING FOR ASIAN AMERICAN PACIFIC ISLANDER SEXUAL AND GENDER MINORITIES
Stephanie Bi¹; Kathryn E. Gunter¹; Fanny Y. López Benítez²; Seeba Anam¹; Judy Y. Tan³; Danielle J. Polin¹; Justin L. Jia⁴; Neda Laiteerapong¹; Mai T. Pho¹; Karen Kim¹; Marshall Chin¹. ¹University of Chicago, Chicago, IL; ²Dominican University, River Forest, IL; ³University of California San Francisco, San Francisco, CA; ⁴Stanford University, Stanford, CA. (Control ID #3180546)

BACKGROUND: Asian American Pacific Islander (AAPI) sexual and gender minorities (SGM) experience substantial mental health burden and face unique intersectional challenges in mental health burden and accessing high-quality mental healthcare. Shared decision making (SDM) values patient preferences and could be used to improve care for this population, but evidence is scant to inform SDM practices. We aimed to identify barriers and facilitators in SDM for AAPI SGM individuals, especially surrounding mental health, and to provide recommendations for providers.

METHODS: We conducted individual interviews (n=40) and focus groups (n=10) in Chicago and San Francisco to explore SDM experiences in the context of mental health, and multiple identities. An extensive codebook was iteratively amended by eight team members, and the transcripts were each randomly assigned to two coders. After secondary analysis, we developed a conceptual model through an inductive approach guided by a review of the literature.

RESULTS: Fifty-four percent of participants were gay, 33% were queer, 10% were bisexual, 2% were asexual, and 2% did not use labels to describe their sexual orientation. Seventy-four percent of the participants were cis men, 6% were cis women, 8% were trans men, 2% were trans women, and 8% were gender nonconforming or two-spirited. Several racial/ethnic groups within AAPI were represented. Our conceptual model elucidates the patient, provider, and encounter-centered factors that may inform into SDM for AAPI SDM. Some participants shared the stigma of SGM identities and mental health in their AAPI families. Their AAPI and SGM identities were intertwined in impacting mental health. Some providers inappropriately controlled the visibility of the patient's identities, ignoring or overemphasizing them. Participants varied on whether they preferred a provider of the same race, and how prominently their AAPI and/or SGM identities affected SDM.

CONCLUSIONS: Providers can improve the care they provide to AAPI SGM patients if they understand their identity-specific challenges in engaging in SDM. Providers should self-educate about AAPI and SGM history and intracommunity heterogeneity before the encounter, create a safe environment conducive to patient disclosure of SGM identity, and ask questions about patient priorities for the visit, pronouns, and mental health.

Conceptual model for shared decision making between providers and Asian American Pacific Islander (AAPI) sexual and gender minority (SGM) patients

IN-HOME TECHNOLOGY TRAINING TO REDUCE SOCIAL ISOLATION AND IMPROVE TABLET USE AMONG OLDER ADULTS: FINDINGS FROM THE TECH ALLIES PROGRAM

Jessica Fields¹; Anupama Cembali¹; Cathy Michalec²; Debbie Uchida²; Heather DeSmidt³; Jacqueline Cuellar⁴; Anna H. Chodos¹; Courtney Lyles¹. ¹UCSF, San Francisco, CA; ²Little Brothers Friends of the Elderly, San Francisco, CA; ³Community Tech Network, San Francisco, CA; ⁴University of California, Berkeley, Berkeley, CA. (Control ID #3180367)

BACKGROUND: Technology has the potential to increase feelings of social connectedness among older adults, but 1/3 do not use the internet. We formed a community partnership called Tech Allies to provide iPads, internet access, and 1:1 technology training to isolated older adults. Our objective was to evaluate whether participation in the Tech Allies program affected loneliness and technology use among participants.

METHODS: Tech Allies was a partnership: Little Brothers Friends of the Elderly (LBFE, a volunteer organization providing home visits for isolated older adults), Community Tech Network (a digital literacy training organization), and the University of California, San Francisco. Participants were eligible for the study if they were (1) at least 65 years old, or if disabled, at least 50; (2) receive fewer than two social visits per month; (3) English speaking, and (4) able to provide informed consent. Participants were randomized into immediate training and a 2-month waitlist, to function as a

control. LBFE volunteers visited participants weekly and provided 8 weekly lessons on iPad use. Surveys assessed loneliness, using the 3-item UCLA loneliness scale, and self-reported computer use and skills at baseline and follow-up. McNemar's tests were used to assess change over time in loneliness and technology use. A subgroup also completed in-home interviews discussing motivations for internet use and perceptions about technology and health.

RESULTS: 44 participants were randomized into immediate training and 39 into the waitlist. The sample was 51% female, mean age 75, 73% income <\$20K, and 46% nonwhite. Of the training group with complete data in Dec 2018 (n=24), 91% reported loneliness at baseline and 87% at follow-up (p=1.0), and 33% reported no technology use at baseline and 0% at follow-up (p=0.01). Of the waitlist group with complete data in Dec 2018 (n=28), 64% reported loneliness at baseline and 63% at follow up (p=1.0), and 57% reported no technology use at baseline and 64% at follow-up (p=0.63). The qualitative interviews showed isolation was a key driver of program participation, with high self-awareness about how technology may impact isolation. Participants expressed unmet needs regarding technology and health such as, "Sometimes I can't even make it [to the doctor]...I only have a caretaker. I can't drive myself. I don't even have a relative."

CONCLUSIONS: Though participation in Tech Allies did not result in change in loneliness, it did result in an increase in technology use. While other studies have evaluated small-scale digital training for older adults focused on health, this work is the first effort to our knowledge focused specifically on dissemination and implementation of digital training among this high-needs population. Our findings demonstrate that embedding training within existing community-based programs holds promise as a longitudinal and potentially sustainable mechanism to provide digital literacy training to older adults.

INADEQUATE REPORTING OF CO-INTERVENTIONS IN RECENT CARDIOVASCULAR CLINICAL TRIALS: A SYSTEMATIC REVIEW

Elisavet Moutzouri^{1, 2}; Luise Adam²; Martin Feller^{1, 2}; Lamprini Syrigiannouli¹; Bruno R. da Costa^{3, 1}; Cinzia Del Giovane¹; Douglas Bauer⁴; Drahomir Aujesky²; Arnaud Chiolero¹; Nicolas Rodondi^{1, 2}. ¹University of Bern, Bern, Switzerland; ²Inselspital, Bern University Hospital, Bern, Switzerland; ³University of Toronto, Bern, Switzerland; ⁴University of California, San Francisco, CA. (Control ID #3185147)

BACKGROUND: Co-interventions in a randomized controlled trial (RCT) is medical care given in addition to the tested intervention. If co-interventions are unbalanced across trial arms, the results may be biased. Co-interventions have to be adequately reported, particularly in RCTs at risk of bias or without full blinding. The aim of the present study was to describe the reporting of co-interventions, and to evaluate factors associated with the quality of their reporting in recent cardiovascular trials.

METHODS: We performed a systematic review of RCTs evaluating pharmacological interventions on cardiovascular outcomes, published in five high impact journals (New England Journal of Medicine, Lancet, Journal of the American Medical Association, British Medical Journal and Annals of Internal Medicine) from 1 January 2011 through 31 December 2016 (PROSPERO: CRD42018106771). Quality of reporting of co-interventions was evaluated independently by two reviewers, and was considered "inadequately reported" unless the authors reported 1) a list of co-interventions of interest across trial arms, or 2) explicitly stated the absence of potential co-interventions, in which cases it was considered "adequately reported". Furthermore, we assessed the association between quality of reporting and the blinding of participants and/or personnel, the risk of bias due to deviation of intended interventions, the adherence to study treatment, and the duration of follow-up.

RESULTS: Co-interventions were inadequately reported in 65 of 91 RCTs (71.4%), with 38 (41.8%) providing no information on co-interventions and 27 (29.7%) only partial information. Adequate reporting was associated with

adherence to study treatment (odds ratio (OR) 2.86; 95% confidence interval (CI) 1.01 to 8.04), a follow-up duration of less than 6 months (OR 4.25; 95%CI 1.57 to 11.47), but was not associated with blinding (OR 0.88, 95%CI 0.35 to 2.20) or risk of bias due to deviation of intended interventions (OR 2.34, 95%CI 0.91 to 6.02), even though better reporting would have been expected in these RCTs.

CONCLUSIONS: Among recent major cardiovascular trials, over two thirds do not adequately report co-interventions, including among trials that are not fully blinded or judged to be at risk for bias. Co-interventions should be systematically reported, as they may be a source of bias, with a potential risk of marketing drugs that are less effective than what they appear in these trials.

INAPPROPRIATE STATIN THERAPY ACCORDING TO ATHEROSCLEROTIC CARDIOVASCULAR DISEASE (ASCVD) RISK; CAN WE DO BETTER?

Raef A. Fadel; Guneeet Ahluwalia; Courtney Hughes; Shivani Sharma; Ahmad O. Aljamal; Jasmine Omar. Henry Ford Hospital, Rochester Hills, MI. (Control ID #3178659)

BACKGROUND: Statin therapy targeted at reducing 10-year risk of stroke and heart attack has become a cornerstone for preventative health in the outpatient setting. Appropriate statin intensity prescription based on 10-year ASCVD risk calculation can lead to improved morbidity and mortality as outlined by current American College of Cardiology/American Heart Association (ACC/AHA) guidelines.

METHODS: We conducted an empiric observational study in August 2018 based on lab results of patients visiting the Henry Ford Hospital Academic Internal Medicine Clinic between January 2017 and December 2017. We calculated the 10-year ASCVD risk for the patients based on this data, and compared the ACC/AHA guideline recommended statin therapy with the one currently prescribed. The primary outcome was appropriateness of statin therapy based on ASVCD risk calculation. Our aim was to assess whether patients in the clinic setting are being adequately managed for ASCVD risk according to ACC/AHA guidelines.

RESULTS: Of the 2994 patients assessed, approximately 1548 patients were prescribed an inappropriate intensity of statin based on 10-year ASCVD risk calculation (p < 0.001). For female patients, the odds of appropriate statin dose prescription increased by approximately 81.9% (odds ratio 1.1819) when compared to male patients (95% CI 1.559-2.124). For black patients, the odds of appropriate statin dose prescription decreased by 32.2% (odds ratio 1.0678) when compared to white patients (95% CI 0.532-0.864). Asian patients were more likely to be on an appropriate statin dose as compared to non-Asians (p = 0.022), and Hispanic patients were more likely to be on an appropriate statin dose as compared to non-Hispanics (p = 0.005). Approximately 1245 patients currently taking high-intensity statin did not qualify for one based on 10-year ASCVD risk calculation as compared to 484 patients (p < 0.001).

CONCLUSIONS: There is marked discrepancy in the guideline recommended statin therapy (based on 10-year ASCVD risk calculation) and currently prescribed statin, with gender and race serving as major variables. This data demonstrates a major opportunity for intervention on the part of primary care internists to improve patient outcomes in the outpatient setting.

INCORPORATING WALKING SPEED, THE FUNCTIONAL VITAL SIGN IN AN OUTPATIENT INTERNAL MEDICINE RESIDENT CLINIC. A PILOT STUDY

Sara E. Atwater¹; Claudia L. Campos²; Elizabeth L. Tysinger¹; Maria Cranston¹. ¹Wake Forest Baptist Health, Winston Salem, NC; ²Wake Forest University, Winston-Salem, NC. (Control ID #3185565)

BACKGROUND: With rising healthcare costs, more pressure is being placed on primary care providers to provide efficient, yet accurate, thorough,

and cost conscious care. Being able to quickly assess a patient's risk is critical to providers. One metric that risk stratifies and signals earlier health problems is walking speed. It has been described as the functional vital sign or sixth vital sign because of its correlation to mobility, morbidity, mortality and even cognitive function.

METHODS: The outpatient department internal medicine resident clinic at Wake Forest Baptist Health provides 10,000 visits per year. We conducted a pilot during July and August 2018 in patients presenting for a continuity clinic visit. The data collector, a high school volunteer, timed all patients from a starting mark near where all patients are weighed before being brought to the exam room. The stop mark was six meters beyond the starting mark and was denoted with an inconspicuous piece of tape on the railing along the wall. The six meter distance based on a literature review as well as trial and error. The nurses instructed the patients on walking at a comfortable pace. WS was measured with hand held stopwatches and patient's speed was recorded in meters per seconds (m/s).

RESULTS: During the two months of data collection, we measured and recorded walking speed in 36 patients with 61.1% female and 38.9% male participants. There was a wide patient age range from 24 to 75 years old with a mean age of 47.9 years old. The patient average WS was 0.9 m/s with a range of 0.4 to 1.4 m/s. In addition, to the objective measures, information regarding the patient's experience of this measurement was also collected. The patients ranked the experience on a Likert scale of 1-5 with 1 being the most bothersome to 5 being the most pleasant. The average rating was 4.1. They were also asked to rank the helpfulness of this measure on a scale of 1-5 with 1 being the least helpful and 5 being the most helpful. The average score for this was 3.8. Five out of five nurses believed that it was an important metric, but were hesitant to incorporate in routine rooming flows without additional staff to help in the process.

CONCLUSIONS: Patients were very receptive to measuring their walking speed. Nurses were more reluctant given time constraints and rooming flows, but adjusted quickly to the measurement. Evidence continues to validate the prognostic and predictive values of walking speed, and accordingly, the measure's popularity as the "sixth vital sign" has only increased. As with any other vital sign, WS is a simple assessment that provides a wealth of information about underlying physiological processes. The value far out ways the cost, and resident internal medicine clinics should consider incorporating this vital sign into routine clinical practice.

INDIVIDUAL BURDEN OF SOCIAL DETERMINANTS OF HEALTH (SDOH): A NEW RISK FACTOR FOR FATAL CORONARY HEART DISEASE

Monika M. Safford¹; Evgeniya Reshetnyak¹; Madeline R. Sterling¹; Joshua Richman²; Paul Muntner²; Raegan Durant²; John Booth²; Laura C. Pinheiro³. ¹Weill Cornell Medical College, New York, NY; ²University of Alabama at Birmingham, Birmingham, AL; ³Weill Cornell Medicine, New York, NY. (Control ID #3184861)

BACKGROUND: SDOH are associated with poor health outcomes. One of these is death within 28 days of first presentation with coronary heart disease (CHD), also known as incident fatal CHD, which continues to be twice as common in blacks as whites. While much is known about risks associated with individual SDOH, less is known about the burden of SDOH within individuals. We determined the association between the burden of within-person SDOH and risk for incident fatal CHD.

METHODS: This prospective longitudinal study used data from the REasons for Geographic And Racial Differences in Stroke cohort. This population-based national sample of 30,239 community-dwelling black and white adults age >45 years was recruited from 2003-7. Baseline data came from telephone interviews and in-home visits. Telephone follow-ups were conducted every 6 months with retrieval of medical records and expert adjudication of suspected study endpoints including fatal CHD. The primary exposure was SDOH, guided by the Healthy People 2020 framework that includes five domains: social context (black race, social isolation [not seeing

friends/family in the past month]), education (<High School), economic stability (annual household income <\$35,000), neighborhood and built environment (>25% residents in a zip code living below the Federal poverty line), and health/healthcare (lacking health insurance, living in a state with little public health infrastructure). Cox models estimated crude and adjusted associations between the number of within-individual SDOH and incident fatal CHD.

RESULTS: Of 22,152 participants free of CHD at baseline, 58.8% were women and 42.0% were blacks. Over a median 9.2 years of follow-up, the incidence rate of fatal CHD events per 1000 person-years (and number of events) for the 4016 participants with 0 SDOH was 1.18 (45); for the 5944 with 1 SDOH was 1.25 (76); for the 4464 with 2 SDOH was 1.97 (89); and for the 5024 with >3 SDOH was 2.85 (140). Compared to participants with 0 SDOH, the crude hazard ratio (HR) for fatal CHD among those with 1 SDOH was 1.18 (95% CI 0.82, 1.69), with 2 SDOH was 2.02 (95% CI 1.43, 2.84), and with >3 SDOH was 3.00 (95% CI 2.17, 4.15). Following adjustment for medical conditions and treatments, functional status, physiologic variables, and health behaviors, compared to participants with 0 SDOH, the adjusted HR among those with 1 SDOH was 0.95 (95% CI 0.66, 1.38), for those with 2 SDOH was 1.31 (95% CI 0.92, 1.87), and for those with >3 SDOH was 1.67 (95% CI 1.18, 2.37). These findings were consistent for both men and women and older and younger participants.

CONCLUSIONS: An individual's burden of SDOH may be a new marker for risk of death at presentation with CHD. Many of the SDOH studied here are already part of the social history in a standard medical interview, allowing clinicians to quickly and easily identify patients who may benefit from the most aggressive CVD risk factor management until we gain better understanding of the mechanisms leading to these findings.

INFLUENCE OF INDIVIDUAL-LEVEL NEIGHBORHOOD FACTORS ON HEALTH PROMOTING AND RISK BEHAVIORS IN THE HISPANIC COMMUNITY HEALTH STUDY/STUDY OF LATINOS (HCHS/SOL)

Asmi Panigrahi^{2, 1}; Jennifer Bayly^{2, 3}; Erik J. Rodriguez²; Eliseo J. Perez-Stable⁴. ¹Rutgers New Jersey Medical School, Newark, NJ; ²National Heart, Lung, and Blood Institute, Bethesda, MD; ³Rutgers Robert Wood Johnson Medical School, Piscataway, NJ; ⁴National Institutes of Health, Bethesda, MD. (Control ID #3185661)

BACKGROUND: Though people's place of residence is often tied to socioeconomic status, race, and ethnicity, the role of neighborhood environment as a determinant of health remains less clear. Neighborhood environment may be an especially important determinant that influences immigrant and minority health behaviors, particularly among US Hispanics/Latinos. We sought to understand the relationships between individual-level neighborhood factors and health promoting and risk behaviors in the most comprehensive study of Hispanics/Latinos in the US to date.

METHODS: We analyzed data from the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) Sociocultural Ancillary Study which included 5313 men and women, 18-74 years old, recruited from San Diego, Chicago, Miami and New York City, and from Mexican, Puerto Rican, Cuban, Central American, Dominican and South American background. All participants underwent a baseline clinical exam and sociocultural survey including validated measures of neighborhood social cohesion and neighborhood problems. We used multivariable logistic regression to assess cross-sectional and longitudinal relationships between participants' neighborhood factors and health behaviors, adjusting for age, gender, educational attainment and health insurance.

RESULTS: Participants had a mean age of 42.5 years (SD 0.38), 54.8% were women, and 72.8% were foreign born. Mean perceived neighborhood problems were greater in US-born vs foreign-born participants [Mean (SE)=12.9(0.16) vs 11.6(0.14), p<0.001]. Mean perceived neighborhood problems differed by site, and were highest in the Bronx, followed by Chicago, Miami and lowest in San Diego (13.5(0.21), 12.5(0.19),

11.5(0.21), 10.3(0.18), $p<0.001$. However there was no significant difference between mean perceived neighborhood social cohesion in US-born vs foreign-born participants (15.8 vs 15.8), nor by study site (Bronx 15.6, Chicago 15.8, Miami 15.9, San Diego 15.9). Health protective behaviors were consistently less prevalent among foreign-born vs US-born participants, particularly colon cancer screening (50.5% vs 71.5%), mammogram (74.4% vs 84.4%) and prostate cancer screening (51.9% vs 63.3%). Health risk behaviors were also consistently less prevalent among foreign-born vs US-born participants, especially smoking (15.8% vs 31.4%), obesity (36.5% vs 49.9%), and poor diet (16.8% vs 36.6%). Foreign-born participants with higher perceived neighborhood problems were less likely to meet physical activity recommendations [OR (95% CI)=0.74 (0.58, 0.95) $p<0.05$]. Foreign-born participants with less perceived neighborhood social cohesion were less likely to be adherent to pap smear guidelines (OR (95% CI)=0.48 (0.23, 0.98) $p<0.05$).

CONCLUSIONS: Overall, neighborhood factors may significantly influence health behaviors of US Hispanics/Latinos, especially Hispanic/Latino immigrants. Neighborhood environment is important for health systems and providers to consider in prevention and treatment strategies that influence Hispanic/Latino health.

INFLUENCE OF MIDLIFE COGNITIVE ACTIVITY ON LATE-LIFE COGNITIVE ACTIVITY, COGNITIVE FUNCTION AND FUNCTIONAL STATUS IN WI VETERANS

Allison E. Cotter¹; Jessica Kim¹; Kia Semons-Booker¹; Kate Sherman²; Rodney Sparapani³; Jeff Whittle⁴. ¹Medical College of Wisconsin, Wauwatosa, WI; ²Milwaukee VA Medical Center, Milwaukee, WI; ³Medical College of Wisconsin, Milwaukee, WI; ⁴Zablocki VA Medical Center, Milwaukee, WI. (Control ID #3185753)

BACKGROUND: Increased cognitive activity is associated with increased cognitive function in older populations. To test whether midlife cognitive activity might increase late life cognitive function, we studied older (age 68+) male Veterans participating in a longitudinal study of exercise and cognition.

METHODS: We measured current (late-life) cognitive activity using a validated survey (Wilson et. al) which includes such activities as reading books, newspapers or magazines and writing letters; we used a modified version of this survey to ask respondents to recall participation in similar activities at age 50 (midlife). We used standard tests (e.g., Brief Visuospatial Memory Test-Revised (BVMT-R), Wide Range Achievement Test (WRAT-4)) to measure cognitive function. We measured functional status with the physical and mental component scores (PCS12, MCS12) from the Veterans Rand 12 item survey and PROMIS measures of physical and social function. We also asked, "What things influence how much time you spend on mental activity?". We first examined the association of midlife cognitive activity with current cognitive activity and functional status using simple correlations, then used linear regression to examine these same associations, controlling for demographics and other potential confounders.

RESULTS: The 78 participants were largely white (87%), older average (mean age 74.8 years) and well educated (65% had more than 12 years of education; 28% had a college degree). Most (67%) were retired but only 24% had annual household income < \$30k. More education, higher income and white race were associated with increased current cognitive activity. The most common cognitive activity was reading; 76% read "regularly" (more than 1 hour daily) at follow up and 68% reported doing so in midlife. While midlife cognitive activity was positively correlated with current cognitive activity ($p<0.0001$, $r^2=0.3123$), there was no consistent relationship between mid-life cognitive activity and current cognitive function or functional status. Adjustment for potential confounders using multivariable analysis produced similar results. In our qualitative analysis, many respondents reported that much of their cognitive activities are embedded in everyday life (finances, healthcare). These activities are not captured in the cognitive activity measure that we used.

CONCLUSIONS: Higher levels of midlife cognitive activity were associated with more late-life cognitive activity but not improved function. The surprising lack of association between cognitive activity and cognitive function may reflect a healthy volunteer effect. Moreover, our qualitative work identified important cognitive activities that were not captured in our measure of cognitive activity. Our results do suggest that efforts to increase late-life cognitive activity may need to start earlier, when patterns of behavior are established.

INFLUENCES OF PROVIDER GENDER ON UNDERLYING COMMUNICATION SKILLS AND PATIENT CENTEREDNESS IN PAIN MANAGEMENT CLINICAL SCENARIOS

Jeffrey Wilhite; Harriet Fisher; Khemraj Hardowar; Lisa Altshuler; Sarah Chaudhary; Sondra Zabar; Adina Kalet; Kathleen Hanley; Colleen C. Gillespie. NYU School of Medicine, New York, NY. (Control ID #3185434)

BACKGROUND: For quality care, physicians must be skilled in diagnosing and treating chronic pain. Some studies have shown gender differences in how providers manage pain. And more broadly, female providers provide more patient-centered communication which in turn has been linked to patient activation and satisfaction with care. We explore, using Unannounced Standardized Patients (USPs), whether resident physician gender is associated with the core underlying skills needed to effectively diagnose and management chronic pain: communication, patient centeredness, and patient activation.

METHODS: We designed two USP cases and sent these undercover patients into primary care clinics at two urban, safety-net clinics. The USP cases were similar: a 30-35 y.o. male, presented as a new patient to the clinic with either shoulder pain induced by heavy lifting or knee pain due to a recreational sports injury. USPs completed a post-visit checklist that assessed patient satisfaction (4 items), patient activation (3 items), and communication skills (13 items) using a behaviorally-anchored scale (*not done or partly done* vs. *well done*). Summary scores were calculated for each of the three domains. Residents provided consent for their educational data to be used for research as part of an IRB-approved medical education registry.

RESULTS: A total of 135 USP visits (80 female providers, 55 male) occurred between 2012 and 2018. Female providers saw 41 shoulder pain and 39 knee pain cases while male providers saw 21 shoulder and 34 knee cases. ANOVA was used to assess differences in summary scores by provider gender (male vs female) and by case portrayed (knee vs shoulder). Skills did not differ significantly by whether knee or shoulder pain case. Gender effects were not seen for patient centeredness or for patient activation; however female providers performed significantly better at relationship development (83% vs males 72% shoulder pain; 70% vs 66% knee pain case; $p<.001$) and information gathering (86% vs. males 72% shoulder pain; 79% vs 66% in knee case; $p<.016$). Male providers, however, performed slightly better in patient education and counseling (65% vs 63% for shoulder and 38% vs 33% for knee cases; $p<.001$).

CONCLUSIONS: Developing a relationship and gathering information are critical to pain management and female residents performed better than male residents in these areas. Male providers performed slightly better than women in patient education and provider gender was not associated with any differences in patient centeredness or activation. In the future, we plan to link these underlying skills to pain management decisions, documentation and ultimately to patient outcomes. We suspect that patient activation may best be measured at follow-up, something not possible with our current USP methodology. Gender differences could be viewed as striking in the context of our relatively homogeneous sample (medicine residency program) and shared clinical environment/healthcare system.

INFLUENZA MANAGEMENT VIA DIRECT TO CONSUMER TELEMEDICINE

Kathryn A. Martinez¹; Mark N. Rood²; Michael B. Rothberg¹. ¹Cleveland Clinic, Cleveland, OH; ²Cleveland Clinic Foundation, Chagrin Falls, OH. (Control ID #3180272)

BACKGROUND: Influenza is easy to clinically diagnose during an epidemic, and immediate treatment can shorten symptom duration. Direct to consumer (DTC) telemedicine connects patients with physicians 24 hours a day through mobile applications. Telemedicine may be an ideal setting in which to treat influenza, offering access to immediate care without exposing others to infection. Diagnosis outside of influenza epidemics requires rapid testing, which cannot be performed virtually, exposing patients to overtreatment. Patterns of care for influenza in DTC telemedicine are unknown. The objective of this study was to characterize care seeking, diagnosis and treatment for influenza in a large DTC telemedicine platform.

METHODS: This study uses data from the AmericanWell DTC telemedicine platform. Encounters were conducted with physicians between July 2016 and August 2018. Upon connecting with the telemedicine system, patients were asked to describe their call reason using a free text field. Whether they stated their call reason was influenza was assessed. Patients also provided age and insurance information, if applicable (visits cost \$59 out of pocket). Influenza epidemics over the two-year study period were identified based on the Center for Disease Control's Weekly U.S. Influenza Map (December 24, 2016 to April 15, 2017 and December 2, 2017 to April 14, 2018) and encounters were categorized as taking place during an epidemic or not. Tamiflu prescriptions were identified via National Drug Codes associated with each encounter. We described patterns of care for influenza during epidemics versus not.

RESULTS: During the two year study period, 8,055 patients were diagnosed with influenza, of whom 16% were 18 years or younger, and 45% were between 19 and 39 years. Eighty eight percent of influenza diagnoses occurred during epidemics. Among those diagnosed with influenza, 80% received Tamiflu. The proportion of influenza patients receiving Tamiflu did not vary by epidemic status (80% during epidemics vs. 78% at other times). The majority of patients who were not diagnosed with influenza but nonetheless prescribed Tamiflu were diagnosed with viral illness, unspecified. Of the 8,112 patients who stated their call reason was influenza, 66% called during an epidemic. The proportion of these patients subsequently diagnosed with influenza varied by season: 52% were diagnosed with influenza during epidemics, versus 11% at other times.

CONCLUSIONS: Physicians treating patients with influenza symptoms were more likely to diagnose and treat patients during an epidemic. Prescription of Tamiflu at other times without rapid testing probably represents inappropriate care. DTC telemedicine represents a promising venue for treating influenza with antiviral medication, but provider education may be required.

INITIATIVE TO IMPROVE COLORECTAL CANCER SCREENING RATES AT A FEDERALLY QUALIFIED HEALTH CENTER

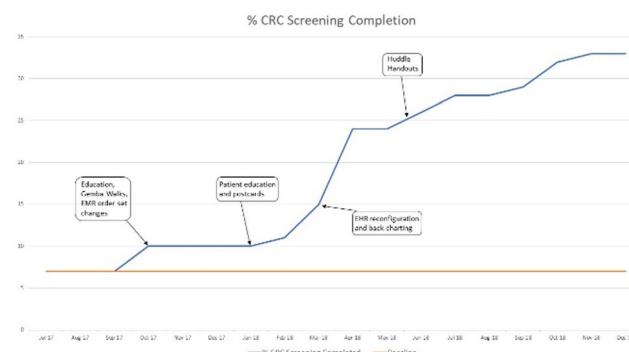

Kyle T. Kunz; Swaroop Vitta; Kathryn Parker. Washington University in Saint Louis, Saint Louis, MO. (Control ID #3185473)

BACKGROUND: Colorectal cancer (CRC) is the third-leading type of cancer and cause of cancer-related death for both men and women in the United States. Improved awareness and screening has led to earlier discovery and CRC-related deaths have been declining in recent decades. Based on guidelines, screening rates are still reported at only 63% nationally. Lower screening rates (40%) and more frequent late stage discoveries occur in disadvantaged patient populations that are more apt to use federally qualified healthcare centers (FQHC). As a quality improvement initiative, we sought to increase CRC screening rates at a single FQHC.

METHODS: This study was performed at a single multilocation FQHC. After gathering baseline data from July 2017 through October 2017, 4 PDSA cycles were conducted from October 2017 through June 2018 including (1) Provider education, Gemba walks, EHR (electronic health record) order set changes (2) Patient education with postcards and in-person nursing education (3) EHR reconfiguration and back-charting uncaptured results (4) Pre-shift huddle with medical assistants to identify patients with inadequate screening. All prior interventions were continued in addition to the subsequent interventions for each cycle. Data for screening results was gathered from Azara Healthcare, a community health center data reporting agency which draws from our EHR.

RESULTS: The baseline screening rate was 7% which ranked as the lowest for FQHCs in the state. Cycle 1 had the least impact with increased screening rates to 10% from October 2017-January 2018. Cycle 2 from January 2018 through March 2018 increased screening rates from 10% to 15%. Cycle 3 had the most significant impact increasing screening rates from 15% to 26% from March 2018 through June 2018. Rates continued to increase from 26% to 33% during cycle 4 from June 2018 through December of 2018.

CONCLUSIONS: In a vulnerable patient population at single FQHC, CRC screening rates were improved and showed sustained rates with the above interventions. Consistent with prior quality improvement studies, EHR interventions provided the most significant increase likely due to noncaptured results while early education provided least improvement. Incorporation of the healthcare team with huddles also had improvement in screening results consistent with prior studies.

INTEGRATING AN ONLINE WEIGHT MANAGEMENT PROGRAM WITH POPULATION HEALTH MANAGEMENT SUPPORT IN PRIMARY CARE: PRELIMINARY RESULTS FROM THE PROPS STUDY (PARTNERSHIPS FOR REDUCING OVERWEIGHT AND OBESITY WITH PATIENT-CENTERED STRATEGIES)

Heather J. Baer¹; Barbara A. De La Cruz¹; Nyryan V. Nolido¹; E. John Orav¹; Kristina Secinaro³; Ronen Rozenblum¹; Jason P. Block²; Katherine D. McManus³; Florencia Halperin³; David W. Bates¹. ¹Brigham and Women, Boston, MA; ²Harvard Pilgrim Health Care Institute/Harvard Medical School, Boston, MA; ³Brigham and Women's Hospital, Boston, MA. (Control ID #3185584)

BACKGROUND: Primary care providers often do not have sufficient time or training to counsel patients about weight. There is an urgent need for scalable, low-cost weight management strategies that can be easily implemented in primary care.

METHODS: We adapted an evidence-based online weight management program and integrated it with population health management support at primary care practices affiliated with Brigham and Women's Hospital (BWH), an academic medical center in Boston, Massachusetts. The online program consisted of educational sessions, structured meal plans, self-monitoring tools, and automated feedback and reminders. The population health management strategy involved monitoring and support from non-clinical primary care staff. We conducted a pragmatic, cluster-randomized trial in 15 primary care practices (24 clinics) to compare the effectiveness of three strategies: 1) usual care, 2) online program alone, and 3) online program plus population health management support (combined intervention). Participants were ages 20 to 70, had body mass index (BMI) 27 and < 40 kg/m², and had hypertension or type 2 diabetes. They attended regular visits at their primary care practices over 18 months and completed surveys at enrollment and 6, 12, and 18 months after enrollment. The primary outcome is weight change at 12 months after enrollment, calculated from weights measured at primary care visits. Secondary outcomes include changes in cardiovascular risk factors, weight-related quality of life, health status, physical activity, and diet. The

12-month follow-up was completed on November 8, 2018, and the 18-month follow-up will be completed on May 8, 2019. Because follow-up is still ongoing, preliminary results are presented across the three groups, rather than separately by group.

RESULTS: A total of 840 participants were enrolled between July 2016 and August 2017 (326 usual care, 216 online program alone, and 298 combined intervention.) At enrollment, participants' mean age was 59.3 years, their mean weight was 203.1 pounds, and their mean BMI was 32.5 kg/m²; 60% of participants were female, 76% were white, 96.4% had hypertension, and 24.4% had type 2 diabetes. On average, participants lost weight, with a mean decrease of 4.7 pounds over 12 months. There were increases in weight-related quality of life (mean increase of 5.3 points on a 100-point scale), physical activity (mean increase of 5.4 minutes per week), and in excellent or very good health status (14% increase) over 12 months, with small changes in cardiovascular risk factors and dietary factors.

CONCLUSIONS: It is feasible to integrate an online weight management program with population health management support in primary care. Preliminary results indicate that participants lost weight and had improvements in weight-related quality of life, health status, and physical activity over 12 months. Analyses comparing the effectiveness of the three strategies are forthcoming.

INTEGRATING FINANCIAL COACHING AND SMOKING CESSATION COACHING TO REDUCE HEALTH AND ECONOMIC DISPARITIES IN LOW-INCOME SMOKERS

Erin S. Rogers¹; Elizabeth Vargas¹; Marc I. Rosen²; Miguel Barrios-Barrios¹; Mittal Rana¹; John Rezkalla¹; Reynalry Rozon¹; Christina Wysota¹; Scott E. Sherman^{1, 3}. ¹NYU Langone Health, New York, NY; ²Yale University School of Medicine, New Haven, CT; ³VA New York Harbor Healthcare System, New York, NY. (Control ID #3185072)

BACKGROUND: Smoking rates are two times higher among people living in poverty. Low-income smokers face unique barriers to cessation, including high levels of financial distress. Reducing financial distress may improve cessation rates in this vulnerable population. Moreover, cessation of tobacco spending may further alleviate financial distress by freeing-up funds that could go toward essentials (e.g., food). We examined the efficacy of a program that integrates financial management coaching into smoking cessation coaching for low-income smokers.

METHODS: We recruited 359 smokers living below 200% of the federal poverty level in New York City and randomized them 1:1 to receive up to 9 sessions of integrated financial management-smoking cessation coaching or usual care. The financial coaching aimed to help participants move from spending on cigarettes to spending on household essentials, and to help participants access financial resources. Participants completed surveys at baseline, 2 and 6 months to assess smoking and financial outcomes and treatment satisfaction.

RESULTS: Intervention patients were more likely to have made a quit attempt by 6 months than Control participants (81% vs. 66%, p=.03). Abstinence was significantly higher for the Intervention group at 2 months (23% vs 9%, p=.01) and 6 months (30% vs. 10%, p<.005). At 6 months, Intervention participants were less likely to report high levels of stress about their general finances (44% vs. 66% Control, p=.01), high levels of worry about meeting monthly expenses (56% vs 73% Control, p=.01), or high dissatisfaction with their present financial situation (63% vs 75% Control, p<.05). Intervention participants were also less likely to report frequently living paycheck to paycheck (71% vs 88% Control, p=.01) or frequently being unable to afford leisure activities (51% vs 70% Control, p<.05). There was no group difference in the level of confidence in being able to pay for a \$1,000 financial emergency (71% low confidence for both). Among the 71% of Intervention participants who began counseling, 85% reported being very satisfied with the integrated counseling. Fifty-one percent reported that the number of counseling sessions

they received was "just right," while 36% reported that the number was "too few." Out of the participants who quit smoking, 100% reported that quitting smoking helped them financially and 58% described achieving one or more of their post-quit financial goals.

CONCLUSIONS: Integrating financial coaching into our smoking cessation program was feasible and produced significantly higher abstinence rates and reductions in financial distress than usual care. Participants were highly satisfied with the integrated program and felt it helped them financially. Our integrated program can serve as model for addressing the unique needs of low-income smokers.

INTENSIFICATION OF OLDER ADULTS ANTIHYPERTENSIVES AT HOSPITAL DISCHARGE LEADS TO SERIOUS ADVERSE EVENTS WITHOUT LONG TERM BENEFIT

Timothy Anderson¹; Bocheng Jing²; Charlie M. Wray³; Sarah Ngo²; Kathy Fung²; Molly Silvestrini²; Michael A. Steinman^{4, 2}. ¹University of California, San Francisco, San Francisco, CA; ²UCSF, San Francisco, CA; ³University of Chicago, Mill Valley, CA; ⁴SF VA Medical Center, San Francisco, CA. (Control ID #3165998)

BACKGROUND: Transient elevations of blood pressure (BP) are common in hospitalized older adults and often lead clinicians to discharge patients on intensified antihypertensive medication regimens, even when patients are hospitalized for non-cardiac conditions. This practice may expose patients to overtreatment, particularly those whose BP was previously at goal, however the clinical outcomes are unknown.

METHODS: We used national VA and Medicare data to examine veterans age >=65 years with hypertension who were hospitalized in a VA in 2011-2013 for common non-cardiac conditions. Using propensity score matching based on 120 demographic and clinical variables, patients discharged on intensified antihypertensives were compared to those who were not. Competing risk regressions were used to assess all-cause readmissions and serious adverse events (SAE) at 30 days and cardiovascular events at 1 year, accounting for the competing risk of death. The SAE outcome was a composite of emergency department (ED) visits and hospitalizations for injurious falls, syncope, hypotension, electrolyte abnormalities and acute kidney injury. The cardiovascular event outcome was a composite of ED visits and hospitalizations for acute coronary syndrome, stroke, heart failure, and hypertension. The secondary outcome of change in systolic BP was assessed within 1 year of discharge. Matching and analyses were repeated in the subgroup of patients with a pre-hospitalization SBP < 140 mmHg.

RESULTS: The matched cohort included 4056 patients, evenly divided among those who did vs did not receive antihypertensive intensifications, with excellent covariate balance (standardized mean differences for all covariates <0.1). Mean age was 77 years and 3% were female. At 30 days, patients receiving intensifications had a higher risk of SAE events [hazard ratio (HR) 1.41 (95% CI, 1.06 to 1.88); number needed to harm (NNH) 63 (35-368)] and all-cause readmissions [HR 1.23 (95% CI, 1.07 to 1.42); NNH 27 (16-76)]. At 1 year, there was no difference in cardiovascular events [HR 1.18 (95% CI, 0.99 to 1.40)] and no difference in change in SBP among those who did vs did not receive intensifications [mean BP 134.7 vs 134.4, difference-in-differences 0.6 mmHg (-2.4 to 3.7)]. Among the 2244 matched patients with SBP<140 prior to hospitalization, patients receiving intensifications had a higher risk of SAE events and readmissions at 30 days and cardiovascular events at 1 year (all P<0.05).

CONCLUSIONS: Among older veterans hospitalized for non-cardiac conditions, those discharged on intensified antihypertensives had no difference in BP control or cardiac events at 1 year but had a substantially increased risk of serious adverse events and readmission at 30 days, with a number needed to harm of up to 27. Our findings indicate that the common practice of intensifying antihypertensive regimens during hospitalization poses greater risks than benefits and should be reserved for patients whose reason for hospitalization is related to BP control.

INTER-HOSPITAL RETURN TRANSFERS: AN UNTAPPED OPPORTUNITY TO IMPROVE ACCESS TO TERTIARY CARE.

Maleka Khambaty¹; Stacia Kirkland²; Keri Rateliff²; Michael Rhodes³; Karyn Baum³; Michael Usher¹. ¹University of Minnesota Medical School, Minneapolis, MN; ²Fairview - MHealth, Minneapolis, MN; ³University of Minnesota, Minneapolis, MN. (Control ID #3185865)

BACKGROUND: More than a million people are transferred between hospitals on a yearly basis in the US. Patients are transferred to tertiary and quaternary care centers for specialty expertise, critical and surgical care, and multidisciplinary resources. Due to the increasing age, complexity, and need for subspecialty services, the demand for inter-hospital transfers is likely to rise, and efforts to efficiently manage this population is necessary. Internationally, regional hospital networks have arisen to streamline flow of patients across hospitals. Several studies have demonstrated safe return of adult patients with acute coronary syndrome, trauma, and cerebrovascular accidents to referring medical centers. In this study, we describe the current state of US inter-hospital return transfers in a large, multistate cohort of patients.

METHODS: We utilized the Healthcare Cost and Utilization Project's State Inpatient and Emergency Department Dataset, (FL, IA, VT, UT, and NY from 2011-2013), identifying transfers by matching patient ID (visitlinkID), age, gender, and transfer date. Our primary exposure variable was whether a patient was returned to the originating hospital following an inter-hospital transfer. Patient level factors such as age, gender, race, payer, and charslon comorbidity index, and admitting diagnosis were compared. Additionally, encounter and hospital differences were compared including length of stay, cost, inpatient mortality, hospital ownership and rural/urban location. Between group comparisons were made by chi-square and t-test where appropriate.

RESULTS: Of 358,354 patient transfers only 1.6% were returned to their originating hospital. These patients were older on average (57.5y vs 61.9y p<0.001), more likely to be non-white, with payment by Medicare, and a higher Charleston comorbidity index (p<0.001). Return transfers involved a markedly longer length of stay: total of 5 vs 23 days, higher total charges, (\$48K vs \$274K p<0.001) and nearly twice the inpatient mortality (6.7% vs 11.2%, p<0.001). Hospitals involved in the coordination of return transfers, meaning they were responsible for accepting then referring, were more likely to be urban and for-profit (19.7% vs 37.7% p<0.001). These differences remained consistent across several admitting diagnoses including acute myocardial infarction, cerebrovascular disease, and traumas.

CONCLUSIONS: Inter-hospital transfers are an understudied public health challenge. The unidirectional nature of transfers has the potential to over-burden tertiary care facilities as need increases. These data highlight the untapped potential to improve efficiency by which hospital-based subspecialty care is administered: return transfers. While other countries including Canada have shown return transfers after low risk procedures to be safe, this was not observed to occur in the US, where return transfers appeared to be a last resort for length of stay outliers.

INTERHOSPITAL TRANSFER IS ASSOCIATED WITH INCREASED IN-HOSPITAL MORTALITY ON INTERNAL MEDICINE SERVICES

Marc Heincelman¹; Andrew Schreiner¹; Elizabeth B. Kirkland²; Samuel O. Schumann¹; Jingwen Zhang²; Patrick D. Mauldin¹; Mulugeta Gebregziabher²; William P. Moran¹. ¹Medical University of South Carolina, Charleston, SC; ²MUSC, Charleston, SC. (Control ID #3171238)

BACKGROUND: National administrative datasets have demonstrated worse outcomes among patients undergoing interhospital transfer (IHT); specifically increased risk-adjusted mortality, adverse events, cost, and length of stay, compared to patients admitted through the emergency department (ED). Although national administrative datasets are excellent

for preliminary studies, limitations include the inability to adjust for disease-specific conditions and other patient level clinical characteristics. In this single center study, we investigate the independent association between IHT status and in-hospital mortality, after adjusting for disease-specific conditions and other clinical variables not available in larger administrative datasets.

METHODS: We performed a retrospective cohort study of all adult patients admitted to Internal Medicine services from July 1, 2013 to June 30, 2014. The primary outcome was in-hospital mortality. Four Cox regression analyses were performed to examine the independent association between IHT status and in-hospital mortality, controlling for covariates that were potential confounders to the relationship between transfer and death. Model 1: IHT status, admit service. Model 2: IHT status, admit service, patient demographics. Model 3: IHT status, admit service, patient demographics, disease-specific conditions. Model 4: IHT status, admit service, patient demographics, disease-specific conditions, clinical variables.

RESULTS: Of the 7571 patients included in the cohort, 6% (438) experienced in-hospital mortality. IHT patients accounted for 38% (165) of all in-hospital deaths, despite accounting for only 18% (1393) of total admissions. In an attempt to determine whether IHT status was associated with in-hospital mortality, we performed several Cox proportional hazard regression analyses. Model 1 demonstrated a hazard ratio (OR) of 1.876 for IHT status, after adjusting for admitting service. Model 2 demonstrated a hazard ratio of 1.842 for IHT status, after adjusting for admitting service and patient demographics. Model 3 demonstrated a hazard ratio of 1.810 for IHT status, after adjusting for admitting service, patient demographics, and disease-specific conditions. Model 4 demonstrated a hazard ratio of 1.564 for IHT status, after adjusting for admitting service, patient demographics, disease-specific conditions, and patient laboratory data and vital signs. The integrated time-dependent AUC for model 1 was 0.74, AUC for model 2 was 0.79, AUC for model 3 was 0.82, and AUC for model 4 was 0.89, consistent with a good prediction model.

CONCLUSIONS: After adjusting for patient-level clinical characteristics including vital signs, laboratory data, and individual comorbidities, IHT status remains independently associated with in-hospital mortality.

INTERNAL MEDICINE RESIDENT MATRICULATION INTO CARDIOLOGY FELLOWSHIPS: ASSOCIATIONS WITH CAREER INTENT, MEDICAL KNOWLEDGE, AND PUBLICATIONS

Michael W. Cullen; Kyle W. Klarich; Andrew J. Halvorsen; Amy Oxentenko; Thomas J. Beckman. Mayo Clinic, Rochester, MN. (Control ID #3182576)

BACKGROUND: Unique traits of internal medicine (IM) residents who matriculate into subspecialty fellowships, particularly cardiovascular (CV) diseases, are poorly understood. We sought to identify characteristics of IM residents who successfully match into CV fellowships.

METHODS: We conducted a retrospective cohort study of 8 classes of IM residents who matriculated into residency from 2007-2014 (graduating classes of 2010-2017). Residents not completing 3 years of residency were excluded. The primary outcome was a successful match to a CV fellowship within 1 year of completing IM residency. Independent variables included residents' licensing exam scores, research publications, medical school reputation, Alpha Omega Alpha (AOA) membership, declaration of intent to pursue CV in the residency application personal statement, performance during residency based on clinical evaluation, mini-clinical evaluation exercise (mini-CEX), and in-training exam (ITE) scores, and exposure to CV during residency based on time of first rotation and choice of a CV elective rotation. Data were analyzed by logistic regression.

RESULTS: Of the 339 included residents (59% male; mean age 27) from 120 medical schools, 73 (22%) matched to CV fellowship. At the time of residency application, 104 (31%) had 1 publication, 38 (11%) declared intention to pursue CV in their residency application personal statement,

and 104 (31%) were members of AOA. Prior to fellowship application, 111 (33%) completed a CV elective rotation. At the completion of residency training, 108 (32%) had 3 publications. Multivariable logistic regression revealed that declaration of intention to pursue CV (OR 6.4, 99% CI 1.7-23.4; p<0.001), completion of a CV elective (OR 7.3, 99% CI 2.8-19.0; p<0.001), percentile score on the CV portion of the PGY-2 ITE (OR 1.05, 99% CI 1.02-1.08; p<0.001), and publication of 3 manuscripts (OR 4.7, 99% CI 1.1-20.5; p=0.007) were positively associated with matching to a CV fellowship. Overall PGY-2 ITE percentile score was negatively associated (OR 0.93, 99% CI 0.90-0.97; p<0.001). No associations existed with licensing exam scores, medical school reputation, AOA membership, timing of first CV rotation, mini-CEX scores, or clinical evaluations, both globally and during CV rotations.

CONCLUSIONS: Residents' matriculation into CV fellowships was associated with declaration of CV career intent, completing a CV elective rotation, CV medical knowledge performance, and research publications during residency. These findings may be useful to faculty members who are advising residents about pursuing careers in cardiology. The negative association between matching into CV fellowship and overall ITE knowledge performance may indicate excessive subspecialty focus during IM residency and requires further study.

INTERNAL MEDICINE RESIDENT PROFESSIONALISM ASSESSMENTS ARE ASSOCIATED WITH PATIENTS' OVERALL SATISFACTION WITH THEIR HOSPITAL STAY

John T. Ratelle; Andrew J. Halvorsen; Jayawant N. Mandrekar; Adam P. Sawatsky; Darcy Reed; Thomas J. Beckman. Mayo Clinic, Rochester, MN. (Control ID #3179008)

BACKGROUND: Successful training of internal medicine (IM) residents requires accurate assessments. Patients could provide useful assessments of IM residents in the hospital, yet there is little understanding of how contextual factors may impact on these assessments. Our objective was to explore the potential relationships between patient, resident, and hospital-related factors with standardized patient-of-resident professionalism assessment scores.

METHODS: This was a prospective cohort study of postgraduate year 1 (PGY-1) IM residents and the patients they cared for at Mayo Clinic from July 2015-June 2016. Hospitalized patients provided professionalism assessments of PGY-1 IM residents who were primarily responsible for their care using an instrument that was adapted from published measures. Assessments were obtained on hospital day #4 to optimize the number of patient-resident encounters. Associations between patient-of-resident assessment scores and characteristics of residents (including validated measures of residents' performance and professional behaviors in other settings), patients, and hospital encounters were determined with multivariable modeling using generalized estimating equations to account for repeated assessments of residents. The threshold for statistical significance was p<0.01.

RESULTS: A total of 409 unique patients assessed all 72 PGY-1 residents, with a mean (SD) of 5.7 (3.0) patient assessments per resident. Factor analysis of the 11-item instrument demonstrated two dimensions (Cronbach alpha): "Involvement and Respect" (0.95) and "Compassion and Rapport" (0.94). In the multivariable model, only patients' "top box" ratings of their hospital stay remained significantly associated with their assessments of resident professionalism ($[SE] = +0.7952 [0.0788]; p < .0001$). Notably, patient-of-resident assessment scores in the hospital were not significantly correlated with assessments of resident professionalism in other clinical and educational settings.

CONCLUSIONS: Patients' assessments of resident professionalism in the hospital were positively associated with patients' overall satisfaction with their hospital stays, but were not correlated with

residents' professional behaviors in other settings. Residency programs should consider the potential limitations of patient evaluations before incorporating them into multi-source assessments of trainees.

INTERNISTS' EXPERIENCE WITH TRAINING TO PROVIDE MIFEPRISTONE: A QUALITATIVE ANALYSIS

Mindy Sobota²; Melissa Gosdin³; Jessica Beaman⁵; Suzan Goodman⁴; Maria Catrina D. Jaime³; E. Bimla Schwarz¹. ¹University of California, Davis, Sacramento, CA; ²Brown, Providence, RI; ³UC Davis, Sacramento, CA; ⁴UCSF, San Francisco, CA; ⁵University of California, San Francisco, San Francisco, CA. (Control ID #3186081)

BACKGROUND: Mifepristone (previously known as RU-486) has been a safe, and effective option for US women for almost 20 years; in 2016, the FDA issued an evidence-based update allowing use of abortion pills to terminate pregnancies less than 10 weeks gestation. Although 75% of the 1.2 million US women who seek abortion services each year do so before 10 weeks gestation, currently only 11% of US counties have a clinician who offers abortion services of any kind. As a result, many women must travel substantial distances to access abortion services, which is particularly difficult for low income women who are most likely to face undesired pregnancies.

METHODS: To understand barriers and facilitators to general internists' provision of medication abortion, a medical sociologist conducted semi-structured phone interviews with 8 general internists who have sought training on how to offer mifepristone to patients seeking medication abortion.

RESULTS: All participants reported feeling that reproductive health care is a fundamental component of primary care. Most felt comfortable offering counseling about contraception and miscarriage. However, participants reported having received limited training about abortion in medical school and even less training on abortion during Internal Medicine residency. Participating internists described medication abortion as a "simple—see one, do one, teach one" clinical service, but reported having needed to seek out independent training opportunities in order to learn how to offer medication abortion services to their patients. Participants noted that "compared to other new medications—like PrEP—mifepristone has just not been marketed to us or our patients." Participants further noted that accredited "continuing medical education (CME)" related to abortion or mifepristone was hard to find. For some participants, FDA regulations requiring that mifepristone be stocked in clinic (instead of in pharmacies) was a hurdle, while other participants noted they had been pleasantly surprised by how supportive clinic staff had been of adding mifepristone to the list of services their clinic offers. Participants noted that patients rarely asked for help managing undesired pregnancy until they routinely informed patients that "if this birth control pill fails...I have pills for that too." Internists reported that their patients greatly appreciated the convenience and privacy of obtaining mifepristone in familiar primary care settings. Participants felt that online training would be helpful to colleagues interested in offering mifepristone for medication abortion and miscarriage management.

CONCLUSIONS: Efforts are needed to increase training opportunities for general internists interested in providing mifepristone. Online training, especially if CME-accredited, may increase the number of internists able to provide mifepristone for medication abortion and miscarriage management.

INTERVENTIONS TO REDUCE AGGRESSIVE CARE IN THE LAST YEAR OF LIFE AMONG CANCER PATIENTS: A SYSTEMATIC REVIEW

Nauzley C. Abedini¹; Rachel K. Hechtman¹; Achintya D. Singh²;

Jason Mann¹; Rafina Khateeb¹; Whitney A. Townsend¹; Vineet Chopra¹.

¹University of Michigan, Ann Arbor, MI; ²All India Institute of Medical Science, New Delhi, India. (Control ID #3152624)

BACKGROUND: Aggressive end of life (EOL) treatments in advanced cancer patients are associated with low-value care and frequently lead to unnecessary hospitalizations. Since 2012, the National Quality Forum (NQF), American Society of Clinical Oncology (ASCO), and Centers for Medicare and Medicaid Services (CMS) have adopted EOL quality measures to reduce aggressive care. Using these measures, we conducted a systematic review of the literature to explore what interventions are associated with reductions in aggressive EOL care in cancer patients.

METHODS: We searched MEDLINE via Ovid, Cochrane, CINAHL, EMBASE, Scopus, and PsychINFO. We developed a comprehensive search strategy using the following concepts: EOL care, aggressive or intense care, and cancer. We included randomized control trials (RCTs), quasi-experiments, and observational studies. Studies that did not have a clear intervention or exposure variable and/or did not explicitly aim to reduce aggressive EOL care or improve quality of EOL care were excluded. We developed a taxonomy to organize our findings using the Systems Engineering Initiative for Patient Safety (SEIPS) model derived from human factors engineering. The study protocol was registered with the PROSPERO register of systematic reviews (CRD42018087528).

RESULTS: Of the 3,881 studies identified by our search, 271 were included based on title and abstract review, and 36 met the final inclusion criteria after full-text review. Five studies were RCTs. Thirty-two studies used validated or nationally endorsed measures of aggressive EOL care, while 26 used additional unendorsed or un-validated measures. Only 8 studies linked quality measures with patient- or caregiver-reported outcomes. Based on our taxonomy of SEIPS work system categories, we found that interventions targeting task-related factors were most common (n=20). These included (1) referral to subspecialty palliative care or hospice; (2) interventions to improve communication and EOL discussions; and (3) primary care visits. Interventions targeting external factors, such as assessing the implications of a new policy for universal hospice care, were least common (n=1). Meta-analysis was not performed due to heterogeneity of interventions and outcome measures. Interventions were highly variable in their ability to significantly improve measures of aggressive care at EOL in cancer patients.

CONCLUSIONS: Quality measures to reduce overly aggressive EOL cancer care, including hospitalizations, are used inconsistently by investigators. Interventions to improve aggressive EOL care have had mixed success. More studies are needed to assess the efficacy of interventions to reduce aggressive EOL care, particularly those that link quality measures with patient- and caregiver-reported outcomes.

INTRODUCING VALUE-BASED CARE TO MEDICAL STUDENTS: A CONTROLLED, PROSPECTIVE, COHORT STUDY OF AN EDUCATIONAL INTERVENTION.

Sara-Megumi L. Naylor¹; Rong Guo²; Allison L. Diamant²; Ming Lee².

¹UCSF, San Francisco, CA; ²UCLA, Los Angeles, CA. (Control ID #3185759)

BACKGROUND: The ongoing crisis in US health care signals a critical need to educate medical students about quality, cost, and how they interact to create value. Some medical schools have incorporated value-based care (VBC) content in their curricula. Most available literature only provide descriptive information about curricular efforts and offer best practices; we currently do not know how these efforts specifically impact medical students when compared to a control group. To address this gap, our study evaluates an educational intervention that teaches medical students about VBC and compares intervention and control groups. We hypothesized that students who participated in the intervention would report higher performance related to VBC than those who did not, and that their higher performance would be sustained.

METHODS: We designed a prospective cohort study and received IRB exemption. We recruited third year medical students between 7/2017 and 4/2018. Out of 137 invited students, 122 (89%) participated. The

intervention sessions consisted of definitions, clinical cases, interactive activities, and resources that highlight VBC. The control sessions were shorter and focused on defining VBC. We collected retrospective pre- and post-survey data after all sessions, and again at the end of the academic year. The surveys used a 5-point Likert scale. Wilcoxon signed rank test and Wilcoxon rank sum test were utilized for data analysis.

RESULTS: We found significant improvement from pre- to post-test scores across all sessions and in all domains following a similar pattern ($p<0.001$). The domain of knowledge improved the most and the domain of attitudes the least. When evaluating the change from pre-to post-test scores between intervention and control groups by domain, we found significant improvement in the intervention group compared to the control group in all domains, with more for the domains of knowledge, skills, and confidence ($p<0.001$), and less for the domain of attitudes ($p<0.01$). When comparing pre- and delayed post-test scores, both intervention and control groups showed significant within-group gains in all domains except knowledge, but we did not find significant difference between intervention and control groups.

CONCLUSIONS: Our study demonstrates that educating medical students in VBC with a concerted effort for students to develop personalized, concrete strategies in their current role as a medical student can increase their self-perceived knowledge, skills, attitudes, and confidence regarding VBC when compared to a control group that receives a general introduction on VBC. Our study design with a control group enriches our findings and gives us greater confidence in the efficacy of our intervention. Our goal is to continue to introduce VBC to medical students with educational interventions that we know have an impact on outcomes, and to help establish long term culture change among medical students to practice VBC in their careers.

INVESTIGATING DIFFERENCES IN LENGTH OF STAY ON TEACHING AND NON-TEACHING HOSPITAL TEAMS

Rebekah J. Walker; Jennifer Good; Kurt J. Pfeifer; Bradley H. Crotty; Mandy Kastner; Jennifer A. Campbell; Navdeep Gupta; Douglas Levine; Joan Neuner; Leonard E. Egede. Medical College of Wisconsin, Milwaukee, WI. (Control ID #3185421)

BACKGROUND: The cost of healthcare in the U.S. is higher per capita than any other country with one of the largest drivers of cost being inpatient costs. With an average inpatient stay costing approximately \$14,650, many hospital systems are investigating ways to decrease lengths of stay while ensuring high quality care. To inform new interventions, our Division of General Internal Medicine (GIM) aimed to investigate length of stay variability by team, as well as whether differences existed by hospitalist-only vs. hospitalist teaching teams.

METHODS: Inpatient encounters with GIM hospitalist oversight were extracted from the medical record over a 10-month period. Length of stay was calculated based on the time between hospital admission and hospital discharge with no removal of outliers. Encounters were assigned to teams based on the team assignment of the attending provider. In addition to comparisons by individual teams, teams were grouped based on whether they were teaching or non-teaching teams staffed by residents in addition to hospitalists. Observation teams and Advanced Heart Failure teams were not included in means of other non-teaching teams as length of stays were expected to differ for these groups. Since length of stay was not normally distributed, it was modeled first using generalized linear models with log link and secondly by quartile regression. Models were adjusted for age, gender, race/ethnicity, insurance coverage, Elixhauser comorbidity count, and whether the hospital stay included time spent in the ICU.

RESULTS: When compared as individual teams, each teaching team had a significantly higher length of stay than a reference non-teaching team regardless of the non-teaching team selected (mean difference ranged from 1.1-1.5 days higher). There were no significant differences between individual non-teaching teams after adjusting for relevant covariates.

When grouping teaching and non-teaching teams together into a mean length of stay, teaching teams again had a longer length of stay after adjustment (mean difference of 1.4 days higher). Based on quartile regression, there were no differences between teaching and non-teaching teams in the lowest quartile (mean stay of 1.34 days), however, teaching teams had longer lengths of stay in the middle and upper ends of the distribution (encounters with mean of 2.74 days and higher).

CONCLUSIONS: Based on these results, process improvement opportunities exist within teaching teams regarding length of stay. Hospitalists have begun discussions regarding differences in discharge process and ways to increase efficiency across teams.

INVESTIGATING THE IMPACT OF VHA CLINICIAN BURN-OUT ON PATIENT-REPORTED ACCESS TO PRIMARY CARE

Taona P. Haderlein¹; Danielle Rose¹; Lisa V. Rubenstein²; Susan E. Stockdale¹. ¹VA Greater Los Angeles Healthcare System, Sepulveda, CA; ²RAND and UCLA, Medford, OR. (Control ID #3183108)

BACKGROUND: Burnout among healthcare professionals is associated with diminished job performance, poor mental and physical health, and increased employee attrition. While the Patient Centered Medical Home Model (PCMH) is associated with positive patient outcomes, the model requires the restructuring of primary clinic workflow and job roles. Past research has shown that organizational changes such as PCMH transformation heighten the risk for employee burnout. However, little is known about subsequent impacts of clinician burnout on patients' experiences. The present study examines VHA clinician-reported burnout as a predictor of patient-reported access to primary care.

METHODS: We merged primary care clinician (PCC) data from the Veterans Assessment and Improvement Laboratory baseline clinician survey, collected from November 2011 through March 2012, with data from the Survey of Healthcare Experiences of Patients (SHEP) administered by RAPID. We included scores from three subscales of the Maslach Burnout Inventory - emotional exhaustion (EE), cynicism (CY), and professional efficacy (PE) - as our primary predictor variables. We used data from patients who were identified as members of the PCCs' patient panels. Our dependent variables were three SHEP items that assessed patient-reported access to 1) routine appointments, 2) urgent appointments, and 3) tests and treatments. Variable responses were dichotomized as 1=always and 0=sometimes, usually, or never. For each outcome variable, we conducted multilevel mixed-effect logistic regression analyses with patient data at Level 1 and PCC data at Level 2. EE, CY, and PE burnout subscales were included in the model as predictor variables. We also included provider and patient characteristics as fixed-effect covariates. We used a robust clustering method to address intercorrelation within healthcare systems.

RESULTS: We analyzed data from 161 primary care clinicians, and 4,171 Veteran patients. Patients of clinicians reporting high CY were less likely to report that they always obtained an urgent appointment (OR: .95, 95% CI: .95-.96) or routine appointment (OR: .96, 95% CI: .92-.99) when needed. Patients of clinicians reporting high EE were more likely to report always getting urgent (OR: 1.02, 95%CI: 1.01- 1.03) and routine appointments (OR: 1.01, 95% CI: 1.00-1.02) when needed. Low PE was associated with reduced patient-reported access to routine appointments (OR: .96, 95% CI: .93-.99). No association was found for access to tests and treatments.

CONCLUSIONS: The influence of burnout on patient-reported access to primary care appointments varies among burnout dimensions. CY and low PE had a negative impact on patient-reported access to primary care appointments, while EE was positively associated with patient-reported access. As past research has linked EE with increased workload, more work is needed to elucidate mechanisms of the relationship between clinician burnout and perceived access to care.

IS DIABETES OCCURRING AT YOUNGER AGES? SURPRISING RESULTS FROM NHANES 2001-16

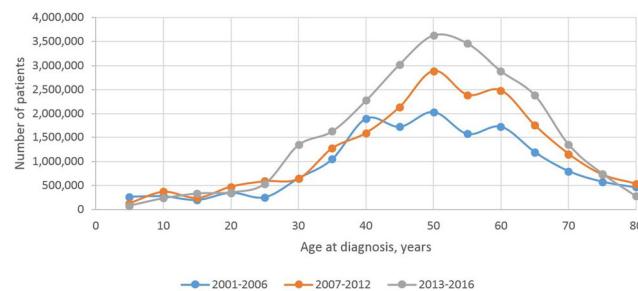

Phuc H. Le¹; Lu Zhang²; Anita D. Misra-Hebert¹; Glen B. Taksler¹; Michael B. Rothberg¹. ¹Cleveland Clinic, Cleveland, OH; ²University of Texas School of Public Health, Houston, TX. (Control ID #3185652)

BACKGROUND: Diabetes affects 9.4% of US adults. The American Diabetes Association recommends screening asymptomatic patients at no later than 45 years old and overweight or obese adults with risk factors at any age. There is a common belief that diabetes is occurring more frequently in young adults, but whether the age at diagnosis has changed is unknown. We aimed to describe population-based trends in mean age at diabetes diagnosis from 2001-2016 among US adults.

METHODS: We conducted a retrospective analysis of National Health and Nutrition Examination Survey (NHANES) data from 2001-2002 through 2015-2016. We included participants aged 18 years and defined diabetes as having ever been told they had diabetes, HbA1C >6.4%, or fasting plasma glucose >125 mg/dL. Pregnant women and participants with missing data were excluded. Age at diabetes diagnosis was self-reported. For patients with previously undiagnosed diabetes, we assigned age at the interview as age at diagnosis. Diabetes duration was calculated as the difference between age at interview and age at diagnosis. Mean age at diagnosis and diabetes duration were estimated for each 2-year period and also stratified by patient characteristics and risk factors. Trends were assessed using linear regression. We used Stata 14.2, accounting for the complex survey design of NHANES.

RESULTS: The sample included 46,668 adults, 7,059 (15.1%) of whom had diabetes. Mean age at diagnosis was 48.2 years and mean diabetes duration was 11.3 years, neither of which changed over time (p for trend>0.05). In all years, age at diagnosis was younger for those who were severely obese, poor, uninsured, Hispanic, or Black; had a family history of diabetes; or were current smokers or excessive alcohol users. Compared to 2001-2006, the number of patients diagnosed in 2013-2016 was 2x, 1.8x and 1.7x higher for ages 30, 50, and 70 years, respectively (figure).

CONCLUSIONS: Mean age at diagnosis did not vary throughout the study period. However, the absolute number of 30-year-olds diagnosed doubled, creating the appearance that diabetes was occurring at younger ages.

IS TAPERING OR DISCONTINUATION OF OPIOID THERAPY ACCELERATING OR TARGETING VULNERABLE POPULATIONS? EVIDENCE IN MEDICARE FROM 2011-2016

Michael L. Barnett^{1,3}; Marema Gaye¹; Hannah Neprash². ¹Harvard T.H. Chan School of Public Health, Boston, MA; ²University of Minnesota School of Public Health, Minneapolis, MN; ³Brigham and Women's Hospital, Boston, MA. (Control ID #3181472)

BACKGROUND: Intense scrutiny of opioid prescribing from regulatory agencies and state governments has coincided with a 29% drop in opioid prescribing volume since 2011. Many observers fear that this trend reflects increasing rates of tapering or discontinuation of long-term opioid

therapy for vulnerable patients. However, little evidence exists regarding trends in tapering or discontinuation of chronic opioid use or patient characteristics associated with de-escalation of therapy.

METHODS: We examined claims from a 20% sample of Medicare beneficiaries with 24 months of continuous enrollment who initiated chronic opioid therapy from 2011-2016. We defined incident chronic opioid use for any beneficiary as >60 days of opioids supplied in each of 2 consecutive quarters. Exposures included "tapering": two consecutive quarters with >25% decrease in average daily morphine equivalent dose from the prior quarter, and "discontinuation": two consecutive quarters with no opioid prescriptions filled. We examined the characteristics of beneficiaries associated with continuous chronic opioid use vs. those with tapering or discontinuation comparing them with ANOVA tests and Cox proportional hazard models to estimate changes in the risk of tapering or discontinuation by year of chronic opioid initiation controlling for beneficiary characteristics and state fixed effects.

RESULTS: Out of 4.8 million beneficiaries from 2011-2016, 268,940 (5.5%) initiated an episode of chronic opioid use for a median of 1.5 (IQR 1.0-2.5) years. Among chronic opioid users, 72,877 (27.1%) tapered and 11,365 (4.2%) discontinued therapy. Compared to those with continued opioid use, beneficiaries with tapering or discontinuation were more likely to be eligible for Medicare through disability (58.7% vs. 64.3% and 61.7%, respectively, $p<0.001$), and more likely to have a prior diagnosis of drug or alcohol use disorder (1.6% vs. 2.4% and 2.2%, $p<0.001$). However, compared to those with continued opioid use, those with tapering or discontinuation had similar or lower average chronic illness burden (0.93 vs. 0.94 and 0.87 mean number of Elixhauser comorbidities, $p=0.009$). Tapering became slightly less common for chronic opioid episodes beginning later in the study period (adjusted hazard ratio for tapering 0.97 per year of initiation, 95% CI 0.96-0.97) while the likelihood of discontinuation was stable (hazard ratio 0.99, 95% CI 0.97-1.00).

CONCLUSIONS: From 2011-2016, a substantial proportion of Medicare beneficiaries used opioids for over 1½ years and close to 1/3rd tapered or discontinued therapy. Discontinuation and tapering of chronic opioid therapy was stable or decreasing for beneficiaries initiating chronic opioid therapy over this period. There was no strongly consistent bias toward vulnerable populations: patients with discontinuation or tapering had more vulnerable features in some ways (e.g. disability, substance use) while in other ways they appeared similar or lower risk (e.g. chronic illness burden).

IS THE PATIENT EXPERIENCE AT ODDS WITH TEACHING IN THE HOSPITAL? AN ANALYSIS OF PATIENT EXPERIENCE RATINGS OF TEACHING AND NON-TEACHING SERVICES

Bradley H. Crotty¹; Rebekah J. Walker¹; Sneha Nagavally²; Jennifer A. Campbell¹; Jennifer Good¹; Navdeep Gupta²; Mandy Kastner¹; Douglas Levine¹; Joan Neuner¹; Kurt J. Pfeifer¹; Leonard E. Egede¹. ¹Medical College of Wisconsin, Milwaukee, WI; ²Medical College of Wisconsin, Milwaukee, Brookfield, WI. (Control ID #3186359)

BACKGROUND: The experience of care is increasingly under scrutiny at academic medical centers (AMCs) with direct and indirect financial implications. A prior single-site study showed that hospitalist-only services had higher patient ratings of communication than teaching services. We sought to assess for differences in patient experience between teaching and non-teaching general medicine services using the standard patient experience survey (Hospital Consumer Assessment of Healthcare Providers and Systems or HCAHPS) given its use as a benchmark instrument.

METHODS: We retrospectively reviewed data from HCAHPS for general medicine discharges between August 2016 and May 2018 at Froedtert Hospital, a 604-bed academic tertiary care center. The sample data is drawn from 845 HCAHP survey responses for discharges during the year 2017. We assessed differences in individual HCAHPS questions focused

on communication, physicians, and discharge information between teaching and non-teaching teams by chi square. We dichotomized the overall rating as satisfied (score of 9) or unsatisfied (<9). Prior to this, we compared illness severity using Charlson comorbidity counts and length of stay (LOS) between teaching and non-teaching services. Patients admitted to teaching and non-teaching services are admitted to the same medical floors.

RESULTS: During this period, there were 216 responses from individuals discharged from the teaching service and 561 responses from those discharged from the non-teaching service. The mean LOS was 4.61 and 4.2 respectively ($p=0.3$) and comorbidity counts were statistically similar (data not shown). For most questions, we did not observe significant differences according to teaching status. We saw no differences across responses for the overall hospital rating or personnel describing side effects, describing medication indications, explaining things in understandable terms, listening carefully, being treated with courtesy and respect, or getting information in writing, about symptoms or problems after discharge. Patients admitted to teaching teams were more likely to report discussions related to meeting needs upon hospital discharge (teaching services 90% vs non-teaching 82% $p=0.02$).

CONCLUSIONS: We identified that teaching services had similar patient experience scores on the standardized HCAHPS instrument as non-teaching services while having statistically equivalent comorbidity and lengths of stay. Teaching teams were rated higher in one communication domain. As hospitals seek to improve their patient experiences, ensuring that the teaching experience does not detract from the patient experience is critical.

JOY IS NOT THE ABSENCE OF BURNOUT

Kavya Sreevalsan¹; Maura J. McGuire^{1, 2}; Colleen Christmas^{1, 2}. ¹Johns Hopkins Bayview Medical Campus, Baltimore, MD; ²Johns Hopkins School of Medicine, Baltimore, MD. (Control ID #3140202)

BACKGROUND: Recently, the growing issue of professional burnout has received much attention. An understanding of the drivers of joy in medicine are only beginning to be elucidated. We aimed to understand the factors that promote joy in medicine in a group of teachers of medical students in primary care settings.

METHODS: We added an optional survey to an existing faculty survey for the primary care clerkship consisting of multiple choice and free responses related to the joy of teaching in the primary care setting. Burnout was assessed using the Mini Z Burnout survey, and results were dichotomized (burned out =rating of 3 or higher on this scale). Respondents rated on a scale from 1 (Always) to 5 (Never) how often they felt joyful during teaching. This item was dichotomized as 2 (joyful when teaching medical students) vs. 3 (not joyful when teaching medical students). We further asked respondents to describe examples of when they felt joyful during teaching encounters and elucidated themes using standard qualitative analyses. Finally, correlation between joy and burnout was analyzed using a chi-squared analysis. The study was approved through the Johns Hopkins Institutional Review Board.

RESULTS: Of the 118 faculty that were included, 43 (36%) opted to respond our additional survey. Of these respondents, 20/43 providers experienced burnout (47%). 32/43 respondents stated they felt joyful while teaching medical students in their practice. In describing a time the respondent felt joyful while teaching, 7 themes emerged: 1. Bearing witness to student growth; 2. Professional Development; 3. Student Motivation; 4. Teacher-Student Relationship; 5. Joyful for Patient's Role in teaching; 6. Sharing Love for What You Do; and 7. Using Personal Expertise. There was no correlation between joy in teaching and burn out ($X^2=0.0066$, $p=0.935$).

CONCLUSIONS: Levels of burnout (47%) were consistent with other studies. The themes related to joy we identified in this study suggest that joy may stem from a fulfilling sense of purpose and identity. Relationships

also appear to have a profound impact on one's perception of joy. We hope our study contributes to better well-being and ultimately can empower the medical system to make changes to promote joy in practice.

LATERAL FEEDBACK IN ACCOUNTABLE CARE UNITS: RESIDENT AND ATTENDING PERCEPTIONS OF INTERPROFESSIONAL FEEDBACK

Katarzyna Mastalerz^{1,2}; Nikki Townsley²; Sarah Jordan². ¹Rocky Mountain Veterans Administration, Aurora, CO; ²University of Colorado, Aurora, CO. (Control ID #3184115)

BACKGROUND: Feedback is an important driver of learner improvement. Physicians are expected to become effective members of interprofessional teams, but little is known about the quality of feedback exchanged between medical trainees and other healthcare professions. In order to understand inpatient team feedback interactions, we interviewed physicians on team based inpatient units called Accountable Care Units (ACU) about their perspectives on interprofessional feedback.

METHODS: We conducted in-person in-depth semi-structured interviews and focus groups with medicine residents and hospitalist attendings in a community teaching hospital between July 2017 and April 2018. The interview guide explored perceptions of interprofessional feedback. Residents that rotated on the ACU and supervising hospitalist attendings were eligible for inclusion. Interviews were audio-recorded, transcribed, and entered into qualitative software for organization (Atlas-ti.v8). During regular group meetings, we systematically analyzed interview transcripts and identified emerging themes using inductive thematic analysis. Saturation was reached.

RESULTS: We interviewed 41 medical residents and 10 hospitalist attendings (n=51). Residents were predominantly male (65%) and Caucasian (65%). Attendings were 50% female with an average of 9.5 years in practice. Three key themes emerged about feedback in interprofessional teams: 1) hierarchies and positionality inhibit resident feedback to interdisciplinary staff, 2) feedback from interprofessional staff is highly desired, 3) conditions that enable interprofessional feedback. Residents were reluctant to give feedback to members of other professions given the lack of familiarity with their roles or their workflow. One resident said: *"I think there's this idea of separation of roles, like residents get feedback from their attendings and other residents, nurses get feedback from their charges."* Hierarchies also constrained interprofessional staff from giving feedback to physicians, unless specifically asked. Feedback from hospital staff, especially from nurses, was highly desired by residents. An intern stated: *"The feedback that's more important and will always be more important, is the direct feedback you get from nursing staff."* Study participants recognized conditions on the ACU that enabled interprofessional feedback: a culture of knowing staff names due to common workflow, a clear expectation of interdisciplinary communication, and opportunities for *"lateral"* talk.

CONCLUSIONS: As we strive to integrate physicians into interprofessional teams, feedback from other healthcare professions is essential. Our study identified that interprofessional feedback is desired by physicians but constrained by professional siloes and hierarchies. Strategies that facilitate the exchange of interprofessional feedback, such as creating intentional integrated workflow and setting clear expectations around interprofessional communication, should be considered in future curricular design.

LAW ENFORCEMENT AND IMMIGRANT HEALTH

Amanda Bertram²; Derek W. Braverman²; Dana Goplerud²; Jaime M. La Charite²; Alexandra Norton²; Zackary Berger¹. ¹Johns Hopkins School of Medicine, Baltimore, MD; ²Johns Hopkins University, Baltimore, MD. (Control ID #3183642)

BACKGROUND: US immigration policies and enforcement may make undocumented immigrants fearful of accessing healthcare. Although current immigration policies restrict enforcement in "sensitive locations" including health care facilities, there are reports of enforcement actions in such settings. It is unclear if healthcare professionals know how to respond to immigration enforcement at their facilities. We attempted to evaluate the experience of health professionals with workplace immigration enforcement, their knowledge and training regarding relevant policies, and their beliefs regarding which policies institutions should follow.

METHODS: We conducted a cross-sectional survey of providers via the member portal of the Society for General Internal Medicine. Providers were encouraged to forward this survey to other interested healthcare professionals.

RESULTS: Most survey respondents were attending physicians (69.1%, n=29), with a further 21.4% listing additional administrative roles. A vast majority worked at academic medical centers (90.5%, n=38) and in outpatient settings (83.3%, n= 38). Most lived in the Northeast (40%, n=17) and listed the majority language spoken by their patients as English (85.7%, n=36). 82.5% of respondents were not aware of specific workplace policies regarding immigration-related law enforcement. Few respondents had received training regarding either immigration-related law enforcement (4.76%, n=2) or law enforcement activity in general (9.5%, n=4). Nearly 1 in 5 respondents reported that they were aware of immigration enforcement activities in or near their workplace (19.1%, n=18), and no staff members involved had received training beforehand. Only 24.3% of respondents considered their facility prepared to respond to immigration enforcement. Cited reasons include lack of training (35.5%), lack of known policies (35.5%), deference to immigration law enforcement (9.5%), lack of awareness (6.5%), or complete lack of preparedness (19.4%). Responses to survey questions about policy awareness or training did not vary significantly by region, job description, practice setting or patient language. Awareness of enforcement activity differed significantly by practice setting, with 57% of inpatient providers and 11% of outpatient providers reporting enforcement activity at or near their place of work.

CONCLUSIONS: Surveyed clinicians were largely unaware of workplace policies at their institution regarding responses to immigration enforcement. Few received relevant training in how to respond to immigration enforcement and most did not feel that their facility would be prepared to do so. Institutions should develop appropriate policies and procedures, educate and train staff, and engage with stakeholders to coordinate appropriate and ethical response to immigration enforcement in clinical settings.

LET'S STEP UP THE WAR ON SUPERBUGS IN OUR HOSPITALS: EVALUATING METHODS TO REDUCE STETHOSCOPE CONTAMINATION

Marwa Moussa¹; Morris Jrada²; Amy Otuonye¹; Jessica Hayon²; Michael Phillips². ¹NYU Langone, Staten Island, NY; ²NYU Langone Health, Brooklyn, NY. (Control ID #3167970)

BACKGROUND: Stethoscopes are recognized as a culprit of microbes that has been conclusively demonstrated to transmit microbes from one patient to another and from health care worker to patient. To curb infections, hospitals need to set more rigorous hygiene standards, identify methods to interrupt transmission and develop strategies on sterilizing the diaphragms of the stethoscopes. Furthermore, studies have shown that providers infrequently clean their stethoscopes. In one study, only 48% of providers cleaned their stethoscopes daily or weekly, 37% monthly and 7% reported that they had never cleaned their stethoscope. The objective of this study was to conduct a pilot study comparing efficacy of disposable diaphragm covers to no intervention, defined as their ability to reduce colony count of Methicillin Resistant

Staphylococcus Aureus (MRSA) and reduce bacterial contamination on stethoscope diaphragm surfaces.

METHODS: This was a prospective pilot study using a randomized, controlled, single-blinded, crossover trial design, evaluating the effect of daily stethoscope disposable diaphragm covers vs. uncovered stethoscopes. Upon recruitment, residents on clinical rotations were randomized to receive one of two sealed opaque boxes. If a resident was randomized to the intervention arm, the package included instructions to begin with the covers. If a resident was randomized to the control arm, instructions were to begin with no covers. We instructed the participants to switch arms at 7 days. Laboratory methods: A sterile swab was rolled over the surface of the stethoscope's diaphragm from side to side in a streaking method. We used the chromagar MRSA plates (MRSASelect^{TMII} agar plates) to grow oxacillin resistant, non-enterococal gram positives and the non-selective blood agar plate. Cultures were obtained from each resident's stethoscope diaphragm at the end of every 7 day period. We performed a colony count in 24 hours and 48 hours of incubation.

RESULTS: We enrolled 37 residents, of whom 29 (70%) completed both weeks of the trial. On the log-10 scale, the mean (range) colony count on plain agar was 1.5 (0.0–3.7) during control and 1.6 (0.0–3.0) using covers. For MRSA, the mean (range) log-10 colony count during control was 0.1 (0.0–2.7) and 0.1 (0.0–1.2) under covers. Overall, 7 (11%) cultures were positive for MRSA during control and 6 (9%) using covers. Using mixed models to account for within-subject and within-culture correlation, the covers increased colony count by 0.47 (95% confidence interval, -0.37–1.31) in mean log-10 overall colony count, and increased risk of MRSA+ culture by 0.2 percent (95% confidence interval, -10.0–10.3).

CONCLUSIONS: This well designed study shows disposable diaphragm covers inadequate in reducing bacterial load. It is likely that this study was hindered by a small sample size, therefore a larger study to evaluate the ability of other methods to prevent cross transmission of MRSA and subsequent infections from the stethoscope diaphragm is needed.

LET'S TALK CANNABIS: A QUALITATIVE STUDY OF VETERANS AFFAIRS PROVIDER AND CANNABIS DISPENSARY EMPLOYEE VIEWS ABOUT DISCUSSING CANNABIS WITH PATIENTS

Vivian Christensen³; Shannon Nugent³; Emilio Sulpizio²; Devan Kansagara^{1, 2}. ¹Portland VA Medical Center, Portland, OR; ²Oregon Health and Science University, Portland, OR; ³VA Portland Health Care System, Portland, OR. (Control ID #3185489)

BACKGROUND: Medical and recreational use of cannabis has become increasingly common, and VA clinicians are asked to be prepared to engage in discussions about cannabis with their patients. This qualitative project sought to better understand provider attitudes, beliefs, and knowledge gaps regarding patients' use of cannabis with the ultimate goal of developing educational tools for clinicians to help them discuss cannabis use with their patients.

METHODS: We conducted in-depth, semi-structured interviews with 18 key informants (14 VA employees and 4 cannabis dispensary employees). Interviews were transcribed and analyzed using a predetermined/deductive framework. An inductive approach was then used to identify themes within each thematic framework.

RESULTS: The most common reasons patients seek advice about cannabis from their physicians is for chronic pain, nausea, depression, anxiety, PTSD, and sleep disorders. While clinicians feel comfortable having basic discussions about cannabis, their lack of specific knowledge about terminology, dose, modality, and strain results in hesitation to have in-depth discussions. Moreover, the continued federal distinction of cannabis as a Schedule 1 drug has led some providers to not

engage in the topic altogether. While views vary, clinicians are generally open to the potential benefits of cannabis, though none view cannabis as risk free and most cite a need for more evidence from controlled clinical trials. Potential risks discussed include potential abuse, impact on comorbidities and/or mental health, and forgoing known effective treatments. Clinicians view medicinal cannabis through a traditional pharmacotherapeutic lens and cite lack of regulation regarding product quality and potency, and uncertainty about the potential for interaction with other prescription drugs as concerns. Dispensary employees are comfortable with the imprecise nature of cannabis as a therapeutic agent, believe that cannabis use is largely risk free, and believe that patient stories and employee experience are valuable sources of evidence that support the effectiveness of cannabis in treating symptoms of common diseases and conditions. Dispensary employees were eager to partner more with clinicians and wanted their customers to obtain guidance for cannabis use for medical purposes from their physicians.

CONCLUSIONS: Cannabis has become widely available without the pharmacotherapeutic standardization and evidence to which clinicians are accustomed. The resulting uncertainty along with federal policy are barriers for clinicians to having discussions about cannabis with their patients. Many clinicians are open to the idea of medicinal cannabis, but have mixed feelings and concerns about safety. There are stark differences in how clinicians and dispensary employees view the use of medicinal cannabis, though dispensary employees appear open to collaboration with clinicians to improve patient safety.

LET'S WORK TOGETHER: RESIDENTS' PERCEIVED ABILITY TO COMMUNICATE MANAGEMENT OF CHRONIC DISEASE WITH PATIENTS WITH LIMITED ENGLISH PROFICIENCY

Mia Williams¹; Brian Lewis²; Karen E. Hauer¹; Alicia Fernandez¹.

¹University of California San Francisco, San Francisco, CA; ²University of Wisconsin, Middleton, WI. (Control ID #3175486)

BACKGROUND: In the US there are ~21 million individuals with limited English proficiency (LEP) who are at risk for challenges in health care communication. These challenges can affect health outcomes. Although there is limited data on the ability of residents to communicate effectively with LEP patients, a previous study suggests that IM residents are dissatisfied with their ability to communicate with LEP patients. Determining local experience is important, as training hours and extent of exposure to LEP patients vary greatly across the country.

METHODS: We conducted a focused needs assessment to ascertain UCSF IM residents self-perceived patterns, strengths, and self-efficacy in communication with LEP patients via a vignette-based survey. The survey contained closed and open-ended questions. The latter were analyzed for themes by two researchers.

RESULTS: 41 (77%) Internal Medicine residents responded to the questionnaire. Residents reported receiving little training in skills to communicate with LEP patients in spite of the fact that 45% of residents reported that >25% of their outpatient encounters were with LEP patients. When residents compared their confidence in executing key tasks such as 'Identify patient's agenda' (100% confident to very confident with English speakers vs. 74% with LEP patients) which increased in magnitude as tasks became more nuanced i.e. 'Understand patient's beliefs about diabetes' (87% vs. 18%); this difference was statistically significant across all communication tasks. In the qualitative analysis, the most common barrier residents identified was time, followed by concern about cultural differences and uncertainty in working with the interpreter.

CONCLUSIONS: Our study found that UCSF IM residents have a significant lack of self-efficacy and satisfaction in the care of LEP patients; this gap worsens as the communication complexity of the task

increases. Preliminary themes highlight systems-issues as areas that limit the ability to care for patients who are LEP, but also note areas where education interventions could be helpful (ie: working with interpreters and understanding culture in the context of medical care). Future directions include focus groups to better characterize gaps in knowledge and assess where curricular programming could be implemented to improve resident self-efficacy and the quality of care for LEP patients.

LEVERAGING COMMUNITY-BASED HEALTH PLANNING AND SERVICES (CHPS) PROVIDER INSIGHT AND EXPERIENCE FOR THE DESIGN AND IMPLEMENTATION OF AN INTERVENTION TO SCREEN AND TREAT CARDIOVASCULAR DISEASE IN NAVRONGO, GHANA: A QUALITATIVE STUDY

Ethan P. Wood¹; Katherine L. Garvey¹; Edith Dambayi²; Denis A. Awuni²; Raymond Aborigo²; Elizabeth Jackson³; James Phillips³; Abraham Oduro²; David J. Heller^{1, 2}. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Navrongo Health Research Center, Navrongo, Ghana; ³Columbia University in the City of New York, New York, NY. (Control ID #3185082)

BACKGROUND: Cardiovascular disease (CVD) is the leading cause of morbidity and mortality worldwide as well as in the United States. CVD prevalence is rising in Ghana, and the shift in burden from communicable to non-communicable diseases poses a great challenge to fragile health systems in rural areas like Navrongo. The Community-Based Health Planning and Services (CHPS) initiative has used nurse-led primary care clinics and home visits to decrease child mortality, but does not currently screen or treat CVD or its risk factors. Our previous research in Navrongo identified lack of transportation, equipment, medicines and knowledge as barriers to CHPS CVD care. The goal of this study was to interview CHPS Community Health Officers (CHOs) and their supervisors, Sub-District Officers (SDOs), regarding locally feasible interventions to decrease CVD morbidity and mortality in Navrongo, Ghana based on these data.

METHODS: We conducted semi-structured interviews with 21 CHOs and 10 SDOs from the Kassena-Nankana District, using a qualitative descriptive approach. Participants were asked for their reactions to our previous findings regarding barriers to CVD care. We then asked them to propose and discuss potential interventions, focusing on which interventions might be most feasible and why. The interviews were audio recorded, transcribed, coded and analyzed for themes. Two coders analyzed the interviews using a general content analysis approach, in which themes and categories emerged iteratively. Coding was completed using NVivo software.

RESULTS: Suggested interventions centered on provider and community education, staffing, and logistics. Respondents proposed CVD trainings for providers; community education at durbars (community gatherings); workforce augmentation; and improved resource and equipment accessibility, as well as nurse authorization to prescribe CVD medication, as important aspects of an intervention. Provision of necessary equipment for CVD screening and management was considered the most crucial intervention. CVD training for all clinical staff, including community health volunteers, was also frequently mentioned. CHOs and SDOs expressed enthusiasm for screening and treatment of CVD and its risk factors, citing a high burden of CVD within their communities, as well as optimism regarding its feasibility.

CONCLUSIONS: Clinical staff in this nurse-led primary care program propose several specific interventions to implement CVD care in Navrongo, and feel they are feasible and appropriate. These findings suggest a CVD intervention can be piloted and evaluated through CHPS in Navrongo. This intervention, once developed, implemented and evaluated, can potentially serve as a model for programs that rely on non-physicians to deliver care to rural communities.

LIFETIME RISK OF NON-FATAL FIREARM-RELATED INJURIES IN NEW YORK STATE: RACIAL AND SEX DISPARITIES

Yu-Tien Hsu¹; David C. Chang¹; Numa P. Perez¹; Ya-Ching Hung¹; Maggie Westfall¹; Cassandra M. Kelleher¹; Peter Masiakos¹; Chana A. Sacks². ¹Massachusetts General Hospital / Harvard Medical School, Boston, MA; ²Brigham and Women's Hospital, Boston, MA. (Control ID #3179226)

BACKGROUND: Gun violence is an important public health problem in the US. While the rising national rate of firearm-related deaths is well-documented, data regarding nonfatal firearm injuries and resulting hospitalizations are limited, and the cumulative lifetime risk of nonfatal firearm injuries is unknown.

METHODS: We performed a retrospective analysis using the New York Statewide Planning and Research Cooperative System (SPARCS), which includes all inpatient hospitalizations and emergency department presentations in NY state from 2005 to 2015. We included all patients 15 years of age or older with firearm injuries, defined by ICD-9 and ICD-10 codes, and excluded in-hospital deaths. Projected lifetime risk of nonfatal firearm injuries per 100,000 persons was calculated as the sum of age-specific incidence rates across all age groups, and stratified by sex, race, and county.

RESULTS: A total of 12,699 firearm-related admissions for 12,381 unique patients were included in the study cohort. 2.9% of patients were shot more than once during the study period. The mean number of admissions was 1,155 per year (7.3 per 100,000 persons). Mean age at admission was 28.1 (+/- 11.7) years; most patients were male (90.0%) and black (65.1%). The overall lifetime risk for nonfatal firearm injuries was 87.3 per 100,000 persons. On average, males had a 9-fold increased lifetime risk of having nonfatal firearm injuries compared with females; blacks had a nearly 18-fold increased risk compared with whites. Nonfatal firearm injuries were concentrated in urban counties, such as Albany and Onondaga, which includes Syracuse (Figure 1 shows lifetime risk of nonfatal firearm injuries by county in 2015). Albany had the highest lifetime risk in the state (157.0 per 100,000 people).

CONCLUSIONS: The lifetime risk of nonfatal firearm-related hospitalization in NY state was 87.3 per 100,000 persons. These data highlight substantial disparities, with men, blacks, and residents of urban counties having higher risks. Targeting prevention strategies to these high-risk populations is essential to reducing overall firearm-related injuries.

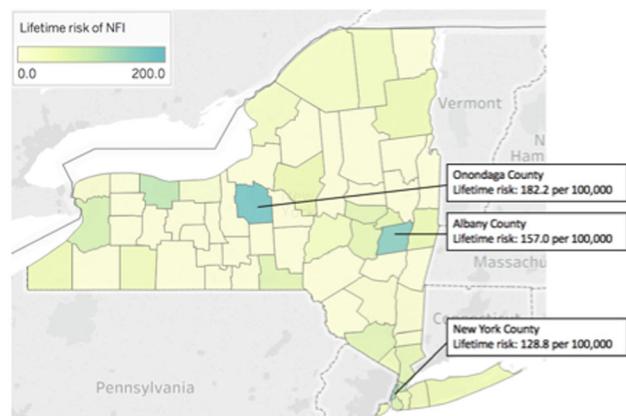

Figure 1: Lifetime risk of non-fatal firearm injuries per 100,000 persons in New York State by county in 2015

LIMITATIONS IN USING AREA UNDER THE RECEIVER OPERATING CHARACTERISTIC CURVE TO EVALUATE MODEL PERFORMANCE FOR LOW FREQUENCY OUTCOMES: APPLICATIONS TO NONCARDIAC SURGERY

Victor J. Lei¹; Edward Kennedy²; ThaiBinh Luong³; Xinwei Chen¹; Daniel Polsky¹; Kevin G. Volpp^{1, 4}; Mark D. Neuman¹; John Holmes¹; Lee Fleisher¹;

Amol S. Navathe^{1,4}. ¹University of Pennsylvania, Philadelphia, PA; ²Carnegie Mellon University, Pittsburgh, PA; ³Penn Medicine, Philadelphia, PA; ⁴Veterans Health Administration, Philadelphia, PA. (Control ID #3183310)

BACKGROUND: Predicting death in noncardiac surgery is important because although death is relatively rare, noncardiac surgeries are very common, with over 25 million procedures per year in the US. In this study, we examined how adding intraoperative data to baseline (pre-hospitalization) and preoperative data can improve prediction of postoperative mortality using the area under the receiver operating characteristic curve (AUROC) versus the area under the precision-recall curve (AUPRC).

METHODS: We conducted a retrospective cohort study of adult patients who underwent major noncardiac surgeries across four hospitals within an academic medical institution from January 2014 to June 2018. We used four modeling approaches to predict all-cause in-hospital mortality: logistic regression, naïve Bayes, random forest, and gradient boosted machine (GBM). Two feature reduction techniques were used to fit the logistic regression models (forward-selection and least absolute shrinkage and selection [LASSO]). 112 clinical variables were extracted and categorized as baseline, preoperative, or intraoperative. Variables were incrementally added to each model and performance was evaluated using AUROC and AUPRC. Though AUROC is an important indicator for model performance, it is not always aligned with how clinicians would use a prediction model. In noncardiac surgery, identifying patients at high risk of death is more critical than identifying patients who do not die. AUROC is immune to changes in class distribution because it is calculated only using sensitivity and specificity and therefore cannot distinguish between models that have equal sensitivity but different precision (positive predictive value). In our context, precision is more clinically meaningful than AUROC, and thus we also examine AUPRC.

RESULTS: Of the 74,147 patients, 512 (0.78%) died in the hospital. The mean age of patients who died after surgery was significantly higher at 65 years vs 56 years for those who survived to hospital discharge. Additionally, patients who died were more likely to be male and covered by Medicare. AUROC increased as more features were added, but predictive performance was high with baseline and preoperative data (AUROC ranged from 0.831 [LASSO] to 0.917 [GBM]) and changes were small when adding intraoperative data (AUROC changes ranged from -0.049 [LASSO] to +0.059 [Logistic with forward selection], p<0.001 for all). In contrast, AUPRC exhibited lower performance with baseline and preoperative data (AUPRC ranged from 0.045 [Naïve Bayes] to 0.235 [GBM]) and large improvements for some models (AUPRC changes ranged from -0.032 [LASSO] to +0.146 [Logistic with forward selection], p<0.001 for all).

CONCLUSIONS: AUPRC is a more clinically meaningful measure than AUROC when predicting low probability events. Further, using AUPRC indicated that adding intraoperative data to baseline and preoperative data improved prediction of postoperative mortality, which would not have been apparent with AUROC.

LIMITED ENGLISH PROFICIENCY AND EFFICACY OF SELF MANAGEMENT SUPPORT SYSTEMS

Leah Machen; Delphine Tuot; Margaret Handley; Neil R. Powe. University of California, San Francisco, San Francisco, CA. (Control ID #3184692)

BACKGROUND: Limited English Proficiency (LEP) is an important driver of health disparities, impaired medical comprehension, and high risk medication use. For many chronic conditions, patient-level interventions to prevent disease progression and its complications have focused on comorbidity management and self-management support (SMS) programs, which rely heavily on patient activation and communication to achieve improved health outcomes. As these interventions evolve, it is crucial to understand if these interventions are similarly applicable to LEP patients compared to English proficient patients.

METHODS: We conducted a retrospective analysis of the KARE (Kidney Awareness Registry and Education) randomized controlled pilot trial to assess

the impact of a comprehensive SMS program on systolic blood pressure (SBP) among individuals with limited (vs. adequate) English proficiency. The 12-month language-concordant, culturally-sensitive SMS program consisted of automated telephone modules, low-literacy written patient-educational materials and telephone health coaching. Impact of the SMS program on change in SBP at 12 months by LEP status was determined using multivariable linear mixed models, controlling for socio-demographic variables and baseline SBP. To explore potential mechanisms underlying differential SMS program impact, engagement with the SMS program (i.e. patient use of educational materials, completion of a health coaching action plan, and duration of automated phone calls), by LEP status was also examined.

RESULTS: Of 137 KARE study participants 53 (38.7%) reported limited English proficiency of which 45 (85%) were Spanish speaking and 8 (15%) Cantonese speaking. While many sociodemographic and clinical variables were similar between groups, individuals with LEP were more likely to be uninsured (39.6% vs. 15.5%, p=0.01) and have less formal education (13.2% vs 47.6% attended some college, p<0.01). Overall, LEP patients randomized to SMS did not have a statistically significant change in SBP compared to English proficient patients randomized to SMS (estimated SBP change: -4.5 (-9.4, 0.3) mmHg for LEP, p=0.07; and -2.1 (-8.6, 4.3) mmHg for English, p=0.51). While LEP and English proficient patients similarly used educational materials provided (82% vs 87%, p= 0.69) and completed a health action plan (81% vs 74%, p=0.49), participants with LEP had significantly longer average automated call duration [3.3 +/-1.4 min vs. 2.2 +/-1.1 min, P<0.01], indicating higher patient engagement.

CONCLUSIONS: Language concordant, culturally appropriate telehealth interventions can be a useful tool in reducing disparities within the LEP population with potential for greater patient engagement and at minimum similar impact on health outcomes compared to English proficient populations.

LOCATION MATTERS: THE TYPE OF HOSPITAL UNIT CAN INFLUENCE SATISFACTION WITH PHYSICIAN COMMUNICATION.

Douglas Levine¹; Rebekah J. Walker¹; Sneha Nagavally²; Leonard E. Egede¹; Jennifer Good³; Bradley H. Crotty³; Mandy Kastner¹; Jennifer A. Campbell³; Navdeep Gupta⁴; Kurt J. Pfeifer¹; Joan Neuner¹. ¹Medical College of Wisconsin, Fox Point, WI; ²MCW, Wauwatosa, WI; ³Medical College of Wisconsin, Milwaukee, WI; ⁴Medical College of Wisconsin, Brookfield, WI. (Control ID #3185787)

BACKGROUND: Patient satisfaction has been shown to predict compliance and is an integral part of providing high quality care. Payers such as Medicare now hold hospitals financially accountable for patient experience as measured by the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey. Predictors of high HCAHPS scores are largely unknown. We sought to determine if the type of hospital unit (general medicine unit or specialty unit) influenced HCAHPS scores for physician communication.

METHODS: We utilized deidentified inpatient care satisfaction data collected from a large academic hospital through the HCAHPS survey from August 2016 through May 2018. Data included demographic information on the patient, discharge provider, length of stay, unit on which patient stayed and their responses to survey topics such as provider communication, overall satisfaction and physician care. Most patients cared for by general internal medicine (GIM) providers at this hospital are admitted to hospital units assigned to the Medicine service, but approximately 30% are admitted to units assigned to other hospital services. Patients of GIM physicians were therefore categorized based on their unit at discharge as medicine or non-medicine. Only hospital stays with a discharging internist/hospitalist provider were included. The overall hospital rating (0-10) was dichotomized to *Not Satisfied* (0-8) and *Satisfied* (9-10) categories. Chi square and t-tests were used to compare patients' hospital experience by whether they were located on a medicine or non-medicine unit.

RESULTS: In this cohort of 1586 patients, 62% were 65 years or older, 56% were female, and 77% self-identified as white. The average overall hospital satisfaction score was 8.9 out of 10 and average length of stay was 4.6 days. Patients treated in non-medicine units had higher overall satisfaction than those in medicine units ($p=0.02$) and higher scores on the question about how often doctors listened to the patient carefully ($p=0.002$). Additional differences that showed a trend towards significance included how often doctors explained things in a way that was understood ($p=0.06$), and how often doctors treated the patient with courtesy and respect ($p=0.06$). In all cases patients treated by GIM providers on non-medicine units responded more favorably than patients treated by GIM providers on medicine units.

CONCLUSIONS: This study demonstrates that the type of inpatient unit can influence both overall satisfaction and satisfaction with physician communication. Differences in the room environment, amenities, and nursing staffing and experience may explain why medicine patients were overall more satisfied when cared for on non-medicine units. These results can inform quality improvement work aimed at improving the patient experience.

LONG-TERM TIME TRENDS OF OPIOID-RELATED HOSPITALIZATIONS AMONG VHA PRIMARY CARE ENROLLEES

Eric Gunnink¹; Karin M. Nelson^{1, 2}; Erin L. Jaske¹; Paul Hebert^{1, 3}; Chuan-Fen Liu^{1, 3}. ¹Department of Veterans Affairs, Seattle, WA; ²University of Washington, Seattle, WA; ³University of Washington School of Public Health, Seattle, WA. (Control ID #3183347)

BACKGROUND: Drug overdose and opioid-related deaths continue to rise in the United States. While the volume of opioid-related hospitalizations was stable from pre-2000 to 2014, the primary diagnosis has shifted from opioid dependence or abuse to opioid or heroin poisoning. The Veterans Health Administration (VHA) cares for vulnerable veterans with high rates of substance use disorder. This study examined the long-term time trends in opioid-related hospitalizations among VHA primary care patients and by payer of the hospitalization, VHA vs Medicare.

METHODS: We conducted a repeated cross-sectional observational study between 2003-2015 using VHA administrative data and Medicare claims. Opioid-related hospitalizations were defined as hospitalizations with an opioid-related diagnosis as the primary diagnosis and were classified into three subgroups: opioid dependence or abuse, opioid poisoning, and heroin poisoning. The study sample included opioid-related hospitalizations in VHA and Medicare settings among VHA primary care patients from 2003 (3,980,807 patients with 3,736 hospitalizations) to 2015 (5,889,338 patients with 6,251 hospitalizations). Among 65+, there were 2,207,625 patients in 2003 with 134 opioid-related hospitalizations in VHA and 92 in Medicare and 3,013,686 patients in 2015 with 407 hospitalizations in VHA and 406 in Medicare. We examined long-term time trends in overall opioid-related hospitalizations, by subgroup of opioid-related hospitalization, and by race/ethnicity. We assessed the time trends by payer among 65 years or older.

RESULTS: The rate of opioid-related hospitalizations rose from 2003 (0.85/1,000 patients) to 2015 (1.06/1,000 patients). We observed increased time trends for opioid poisoning (0.08 to 0.17/1,000 patients) and opioid dependence or abuse (0.76 to 0.87/1,000 patients), but a stable time trend for heroin poisoning (0.01 to 0.02/1,000 patients). Whites contributed the most to the increase in opioid and heroin poisonings with the number of hospitalizations rising from 509 in 2003 to 1,726 in 2015. Among 65+, we observed similar increasing time trends in both VHA and Medicare hospitalizations. The rate of opioid-related hospitalizations rose from 0.06/1,000 patients in 2003 to 0.14/1,000 patients in 2015 in VHA and from 0.04/1,000 patients in 2003 to 0.13/1,000 patients in 2015 in Medicare.

CONCLUSIONS: Like the general population, the opioid-related hospitalization rate increased over time among VHA patients, which was also observed in both VA and Medicare among 65+. However, opioid dependence or abuse and opioid poisoning accounted for most of the increase in VHA, rather than opioid and heroin poisoning observed in the general population. The integrated mental health care for substance use disorder is a key element

of the VHA healthcare system. Future research should examine the impact of integrated mental health care on the long-term time trends of opioid-related hospitalizations.

LONGITUDINAL CHANGES IN ENROLLEES' EMPLOYMENT AND STUDENT STATUS AFTER MICHIGAN'S MEDICAID EXPANSION

Renuka Tipirneni; John Z. Ayanian; Minal Patel; Edith C. Kieffer; Matthias Kirch; Corey Bryant; Jeffrey T. Kullgren; Sarah J. Clark; Sunghee Lee; Erica Solway; Tammy Chang; Adrianne N. Haggins; Jamie Luster; Erin Beathard; Susan D. Goold. University of Michigan, Ann Arbor, MI. (Control ID #3179014)

BACKGROUND: Medicaid "community engagement" requirements (requiring work, school, job searching or community service) are being implemented by states for the first time, but the impact of coverage itself on enrollees' employment and school attendance is unclear. Michigan's Medicaid expansion, or Healthy Michigan Plan (HMP), expanded coverage to ~680,000 low-income individuals beginning in April 2014. Our objective was to assess longitudinal changes in enrollees' employment and student status after HMP enrollment.

METHODS: We conducted a telephone survey of 4,090 HMP enrollees in January-October 2016 (RR=53.7%) and a follow-up survey of respondents in March 2017-January 2018 (N=3,104; RR=83.4%). Sampling was stratified by income and geographic region. Survey items measured employment and student status; demographic characteristics were from Medicaid program files. Eligibility criteria for the 2016 survey were age 19-64, 12 months of HMP coverage and 10 months in a Medicaid health plan; those who agreed to be contacted for follow-up comprised the 2017 population. We used mixed models with time indicators to assess longitudinal changes in the proportion of enrollees who were employed or students, incorporating weights to adjust for sample design and nonresponse. Multivariable logistic regression models were used to identify predictors of being employed or a student.

RESULTS: Among all respondents, 54.3% were employed and/or students in 2016, increasing to 60.0% in 2017 (+5.7 percentage points, OR 1.83, $p<0.001$). In 2017, 76.8% were still enrolled in HMP and 23.2% no longer enrolled. Among those still enrolled in 2017, the proportion of employed/students increased from 53.1% to 58.7% (+5.6 percentage points, OR 1.78, $p<0.001$); among those not enrolled in 2017, the proportion of employed/students increased from 58.2% to 64.1% (+5.9 percentage points, OR 2.03, $p=0.002$). In multivariable analysis assessing predictors of employment/student status, respondents were more likely to be employed if non-Hispanic Black (aOR 1.74, $p=0.009$) or Hispanic (aOR 2.86, $p=0.012$) compared to non-Hispanic Whites, or if they had more education compared to high school (aOR 3.17 for some college, $p<0.001$; aOR 4.82 for Bachelor's degree or higher, $p<0.001$). They were less likely to be employed if age 51-64 compared to age 19-34 (aOR 0.08, $p<0.001$). Improved health status (defined as fair/poor health in 2016 and good/very good/excellent health in 2017) was not associated with employment/student status in 2017 (aOR 0.93, $p=0.826$).

CONCLUSIONS: Employment and school attendance among enrollees in HMP increased from 2016 to 2017. Black, Hispanic and younger adults were more likely to be employed or students in 2017. To our knowledge, this is the first study to assess longitudinal changes in employment and school attendance in Medicaid expansion enrollees. These findings suggest that, irrespective of requirements, Medicaid coverage itself may be associated with the desired outcomes of employment and school attendance.

LONGITUDINAL INVESTIGATION OF OLDER ADULTS' ABILITY TO SELF-MANAGE COMPLEX MEDICATION REGIMENS

Stacy Bailey¹; Lauren Opsasnick¹; Laura M. Curtis¹; Alex Federman²; Julia Yoshino Benavente¹; Rachel O'Conor¹; Michael S. Wolf¹. ¹Northwestern University, Chicago, IL; ²Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3185667)

BACKGROUND: Treatment burden, and specifically polypharmacy, increases with age. Older patients are increasingly being prescribed complex drug regimens that are challenging to self-administer safely and appropriately. Yet few studies have investigated the ability of older patients to correctly interpret and accurately dose multi-drug regimens over time. We sought to investigate whether medication self-management skills are maintained over a decade among a cohort of older primary care patients and what factors might predict declines in one's ability to self-manage complex drug regimens.

METHODS: An NIA-funded cohort study, known as 'LitCog,' was leveraged for this investigation. Beginning in 2008, LitCog enrolled 900 English-speaking adults, ages 55-74 at baseline, all receiving care at either an academic general medicine practice or one of 5 federally qualified health centers in Chicago, IL. At baseline (T1), subjects participated in a structured interview during which were given a standardized seven-drug medication regimen and asked to demonstrate how and when they would hypothetically take all of the medicine within a 24-hour period. To date, 273 LitCog participants have completed the same seven-drug regimen dosing assessment 10 years post-baseline (T4). We compared the mean number of dosing errors at T1 and T4 using a paired t-test and conducted a generalized linear model to assess the change in number of dosing errors over this decade-long period, adjusting for patient demographics, health literacy level, and key covariates. Patient health literacy skills were measured using the Newest Vital Sign.

RESULTS: Participants on average made 2.8 dosing errors (SD, 2.4; range, 0-21) out of 21 potential errors at T1 and 5.0 dosing errors at T4 (SD 2.05; range 0-18) at T2 ($p<0.001$). In a multivariate model controlling for relevant covariates, low and marginal health literacy (low: =1.86; 95% confidence interval [CI]: 1.15 - 2.56, $p<0.001$; marginal: =.55, 95% CI: 0.15-1.09, $p=0.04$), number of chronic conditions at baseline (=0.16, 95% CI: 0.15, 0.30, $p=0.03$), and baseline dosing errors (=-0.79, 95% CI: -0.88, -0.70, $p<0.001$) were all significant, independent predictors of changes in dosing errors over 10 years. Other sociodemographic variables (e.g. age, sex, race) were not significantly associated with dosing errors in bivariate or multivariate analyses.

CONCLUSIONS: Results indicate that regimen dosing errors were common among older patients and increased significantly over a decade of follow-up. Patients with limited literacy skills and those contending with multi-morbidity are at greater risk of making more errors, and consequently becoming less independent in their ability to self-manage multi-drug regimens over time. Findings emphasize the importance of routine counseling for older patients on appropriate medication use to ensure complex drug regimens are taken correctly and safely.

LOW LIBIDO IN OLDER WOMEN: A QUALITATIVE STUDY

Holly N. Thomas¹; Megan Hamm¹; Rachel Hess²; Sonya Borrero³; Rebecca C. Thurston¹. ¹University of Pittsburgh, Pittsburgh, PA; ²University of Utah, Salt Lake City, UT; ³University of Pittsburgh and VA Pittsburgh, Pittsburgh, PA. (Control ID #3183183)

BACKGROUND: A majority of older women are sexually active and consider sex an important part of life. Low libido affects nearly half of women over 60 and is associated with poorer health, quality of life, and relationship satisfaction. The causative factors of low libido in older women are not well understood. In this study, we used a qualitative approach to explore factors that affect libido in older women with low sexual desire.

METHODS: We conducted 15 individual interviews and 3 focus groups (total N=36). Included women were aged 60 years or older, were sexually active with a partner in the prior year, and screened positive for low libido using a validated instrument. Interviews and focus groups were led by trained facilitators using a semi-structured guide with open-ended questions regarding sex and desire. Interviews and focus groups were audio recorded and transcribed. A codebook was developed and refined by two analysts. Five interviews were double-coded to ensure accuracy. Codes were then assigned to all data and key themes were identified.

RESULTS: Mean age was 64.2 (range 60-71). All but two women were non-Hispanic White, 83% were married or living with a partner, and all but one identified as heterosexual. Women highlighted multiple factors that affected libido: (1) physical health, (2) life stressors, (3) psychological factors, and (4) partner factors. In terms of (1) physical health, women detailed how medical problems, low energy, bodily pain, prior gynecologic surgery, and menopause negatively impacted libido. Especially common were vaginal symptoms, including dryness, tightness, and pain. Women often used lubricants or vaginal hormone therapy to adapt to these symptoms, but voiced concerns about messiness, cost, and potential side effects. In terms of (2) life stressors, concerns regarding adult children and dying parents were common. In contrast, some women noted that retiring from work and children leaving the home gave them more time and freedom, resulting in a positive impact on libido. In terms of (3) psychological factors, women discussed concerns about attractiveness, body image, and mood that negatively impacted libido. In terms of (4) partner factors, higher intimacy and relationship satisfaction fostered increased libido, while partner erectile dysfunction (ED) had a negative impact. ED led to less satisfying sexual encounters for women, which in turn decreased their sexual interest. Fear of offending partners or partner defensiveness made communicating about ED challenging. The women noted that older women's sexuality is not discussed enough in our culture, and that speaking with peers about these issues is beneficial.

CONCLUSIONS: Healthcare providers should be aware that there are many factors that affect libido in older women, including physical health, life stressors, psychological factors, and partner issues. Assessment and treatment of low libido in this population requires a multifactorial approach.

LOW NALOXONE PRESCRIPTIONS AMONG INDIVIDUALS AT HIGH RISK OF OPIOID-RELATED OVERDOSE DESPITE HEALTHCARE INTERACTIONS

Sarah Follman¹; Christopher Lytle¹; Vineet M. Arora²; P. Quincy Moore²; Mai T. Pho². ¹University of Chicago, Chicago, IL; ²University of Chicago Medical Center, Chicago, IL. (Control ID #3168608)

BACKGROUND: As opioid-related mortality continues to rise, naloxone remains a critical intervention in preventing overdose death. Expanding access should be optimized to promote equity. Engaging providers to regularly prescribe naloxone is important to advocate for this vulnerable population. The primary goal of our analysis was to determine the extent to which patients at high risk of opioid overdose receive naloxone.

METHODS: Using Truven Health MarketScan®, a national database of commercial insurance claims, we investigated naloxone prescriptions among high-risk patients accessing emergency, inpatient, and outpatient care. We identified patients between October 1, 2015 - December 31, 2016 and grouped them into three categories using ICD-10 codes: 1) patients with opioid misuse or dependence, 2) patients with opioid overdose, and 3) patients with both opioid misuse or dependence and overdose. We then linked patients in each group to their outpatient pharmacy claims. We compared naloxone pharmacy claims by opioid risk group using a Chi-Square test. Additional Chi-square tests characterized the groups across various demographic and healthcare utilization variables. We performed a multivariate logistic regression model to test the association between opioid risk group and naloxone claim, controlling for various demographic and healthcare utilization variables.

RESULTS: Of the 138,108 individuals identified as high-risk opioid users, 2,135 had naloxone claims, or 1.5% of the eligible patients identified. Differences in naloxone claims across opioid risk group were statistically significant ($p<0.001$). Only 1.5% of those with a diagnosis of opioid misuse/dependence and 0.8% of those with an opioid overdose diagnosis received naloxone. Of those with both an opioid misuse/dependence diagnosis and an opioid overdose diagnosis, only 4.6% received naloxone. Overall, 98.5% high-risk patients did not receive naloxone, despite many

interactions with the healthcare system including: 88,618 hospitalizations, 229,680 emergency department (ED) visits, 298,058 internal medicine visits, and 568,448 family practice visits. In the highest risk group, 96% of patients had at least 1 ED visit.

CONCLUSIONS: Within our study population, patients at high risk for opioid overdose rarely received prescriptions for naloxone despite numerous interactions with the healthcare system. Healthcare visits remain a missed opportunity to provide naloxone. Efforts to support prescribing in emergency, inpatient, and in outpatient settings represent an important opportunity to improve naloxone access. This may include policies such as the implementation of naloxone standing orders, protection from civil liability for naloxone dispensing and use, and the addition of co-prescribing recommendations to prescription opioid labeling. Overall, prescribing naloxone as a standard-of-care for high-risk patients addresses a critical patient-care need and helps advocate for this particularly vulnerable group.

LOW PRIORITY OF OBESITY EDUCATION IN INTERNAL MEDICINE RESIDENCY PROGRAMS LEADS TO LACK OF PHYSICIANS' PREPAREDNESS TO EFFECTIVELY TREAT PATIENTS WITH OBESITY: RESULTS FROM THE U.S. INTERNAL MEDICINE RESIDENCY PROGRAM OBESITY EDUCATION CURRICULUM BENCHMARK STUDY

W. Scott Butsch¹; Kathryn Robinson²; Ranita Sharma³; Julianne Knecht⁴; B. Gabriel Smolarz⁴. ¹Cleveland Clinic, Cleveland, OH; ²Penn Medicine Princeton Medical Center, Plainsboro Township, NJ; ³Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; ⁴Novo Nordisk, Inc., Princeton, NJ. (Control ID #3177809)

BACKGROUND: Despite the obesity epidemic in the U.S., physicians are presently under-prepared to treat patients with this disease. This study sought to understand how obesity is currently taught in U.S. Internal Medicine (IM) residency programs. It serves as a benchmark for measuring the degree to which IM residency curricula incorporate topics pertaining to the recently developed Obesity Medicine Education Collaborative (OMEC) obesity competencies.

METHODS: In this cross-sectional study, IM residency program directors were invited to complete an online survey about their curriculum. During the summer of 2018, invitations were sent via postal mail to 501 accredited IM programs. Only one respondent was permitted from each program.

RESULTS: 81 IM residency programs, matching the geographic distribution of U.S. programs, participated in the survey. Although obesity was an intentional program objective for two-thirds of programs (67%), only 2% of respondents believed their residents are "very prepared" to manage patients with obesity with nearly half of respondents reporting their residents are only "somewhat prepared". Formal rotation opportunities in obesity are limited, with approximately one-quarter of programs offering clinical non-surgical rotations in obesity. Most IM residency programs incorporate obesity throughout the curriculum in some form; however, at best, only one-third (35%) of programs reported any one of the known core obesity competencies are covered to "a great extent". In addition, many programs reported psychosocial components of obesity (40%), weight stigma and discrimination (44%), etiological aspects of obesity (65%) and pharmacological treatment of obesity (43%) were covered only to a "very little extent" or "not at all". Competencies reportedly well-covered to are more likely to be taught during teaching rounds, while those covered to a lesser extent are most likely to be taught informally. Lack of room in the curriculum and lack of faculty expertise are the greatest barriers to integrating obesity education. Less than half (40%) of residency programs have discussed incorporating or expanding formal obesity education.

CONCLUSIONS: The obesity curriculum currently taught within U.S. IM residency programs does not adequately cover important aspects that

address the growing epidemic. These results suggest obesity education is not enough of a priority for IM residency programs to evolve their curriculum to incorporate the number one leading health epidemic. Even though weight bias and stigma among medical students and practicing healthcare providers leads to suboptimal care and poor health outcomes, the topic is only covered to a limited extent within many residency programs. Recognizing the importance of providing residents with the education and skills they need to be prepared for managing and treating patients with obesity and formalizing them within IM residency programs will be helpful for graduating residents to be competent in addressing obesity.

LOW-VALUE CARE AND CLINICIAN ENGAGEMENT IN THE MEDICARE SHARED SAVINGS PROGRAM: A SURVEY OF FRONTLINE CLINICIANS

Adam A. Markovitz¹; Michael Rozier³; Susan D. Goold²; John Z. Ayanian²; Edward C. Norton²; Timothy Peterson¹; John M. Hollingsworth². ¹University of Michigan School of Public Health, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³St. Louis University College for Public Health and Social Justice, St. Louis, MO. (Control ID #3185503)

BACKGROUND: Although the Medicare Shared Savings Program (MSSP) created new organizational incentives to improve health care value, Accountable Care Organizations (ACOs) have achieved only modest reductions in the use of low-value care. It is uncertain whether this reflects organizational failure to engage the frontline ACO clinicians charged with implementing ACO objectives. In this study, we asked: Have ACOs successfully engaged frontline clinicians? Is ACO engagement associated with clinicians' reported ability to implement recommendations against low-value care?

METHODS: We designed and administered a survey to clinicians in one of the ten largest MSSP ACOs in the country. Primary exposures included clinicians' participation in ACO decision-making, awareness of ACO incentives, perceived influence on practice, and perceived quality improvement. Our primary outcome was clinicians' reported difficulty implementing recommendations against low-value care (e.g., "Don't recommend cancer screening in adults with life expectancy of less than 10 years"). We used multivariable fixed-effect models to test the relationship between ACO engagement and reported difficulty implementing recommendations against low-value care. In these models, we compared clinicians of the same specialty (e.g., urology), type (e.g., physician), and provider organization (e.g., Michigan Medicine). We used multiple imputation and calibrated survey weights to reduce bias from missing data and survey non-response.

RESULTS: The analytic sample included 1,289 ACO clinicians: advanced practice providers (29%), physician specialists (27%), primary care physicians (18%), internal medicine specialists (16%), and surgeons (10%). Response rate was 34%. We found limited ACO engagement of frontline clinicians: Few clinicians participated in the decision to join the ACO (3%). Few clinicians were aware of ACO incentives, including knowing the ACO was accountable for both spending and quality (23%), successfully lowered spending (9%), or faced upside risk only (3%). Few agreed (moderately or strongly) the ACO changed compensation (20%), practice (19%), or feedback (15%) or that it improved care coordination (17%) or inappropriate care (13%). Clinicians reported difficulty following recommendations against low-value care 18% of the time; clinicians reported patients had difficulty accepting recommendations 36% of the time. Increased ACO awareness (one standard deviation [SD]) was associated with decreased difficulty (-2.3 percentage point [p.p.], 95% confidence interval [CI]: -3.8, -0.7) implementing recommendations, as was perceived quality improvement (1 SD increase, -2.1 p.p., 95% CI, -3.4, -0.8). Participation in ACO decision-making and perceived influence on practice were not associated with recommendation implementation.

CONCLUSIONS: ACO clinicians were broadly unaware of and unaffected by ACO objectives and activities. Limited engagement of ACO clinicians may hamper ACO efforts to reduce low-value care.

LOW-VALUE CARE FOR 4 COMMON CONDITIONS WITHIN THE VETERANS HEALTH ADMINISTRATION

Thomas R. Radomski^{1, 2}; Yan Huang¹; Seo Young Park¹; Carolyn T. Thorpe²; Joshua M. Thorpe²; Michael J. Fine^{2, 1}; Walid F. Gellad^{2, 1}.

¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #3182678)

BACKGROUND: Low-value care is a major driver of wasteful health care spending and exerts physical, psychological, and financial harm upon patients. Whereas low-value care affects up to 43% of Medicare beneficiaries, less is known about its prevalence within VA. Our objective was to quantify the frequency and facility-level variation in the use of low-value diagnostic testing for Veterans managed within the Veterans Health Administration (VA).

METHODS: Among a 20% random sample of all Veterans continuously enrolled in VA in Fiscal Year 2015 (n=1,022,987 Veterans), we applied a claims-based metric used in Medicare to identify unnecessary diagnostic testing for 4 uncomplicated conditions: 1) low back pain, 2) acute sinusitis, 3) headache, and 4) syncope. Examples of such low-value care include low back imaging within 6 weeks of an initial back pain diagnosis without red-flag symptoms and maxillofacial CT imaging for acute uncomplicated sinusitis. For headache, we separately assessed low-value head imaging and electroencephalography (EEG). For syncope, we separately assessed low-value head imaging and carotid ultrasonography. For each condition, we determined the overall percentage of eligible Veterans who received low-value care and the range of low-value care use across 127 VA Medical Centers (VAMCs), adjusting for sociodemographic and VAMC characteristics. We used Pearson's correlation coefficient to determine the correlation between Veterans' use of different types of low-value care for the same condition within VAMCs, focusing on uncomplicated headache and syncope.

RESULTS: Of the 343,024 Veterans who had non-specific low-back pain in FY15, 19,736 (5.8%) received low-value care, with a VAMC range of 3.6-7.7%. Of the 52,889 Veterans who had acute sinusitis, 1,305 (2.5%) received low-value care, with a VAMC range of 1.3-5.1%. Of the 79,176 Veterans with uncomplicated headache, 6,904 (8.7%) received low-value care (head imaging 6,786 (8.6%) and EEG 167 (0.2%)), with an overall VAMC range of 6.2-14.6%. Lastly, 23,776 Veterans experienced uncomplicated syncope, of whom 3,300 (13.9%) received low-value care (head imaging 2,393 (10.1%) and carotid ultrasound 1,390 (5.9%)), with an overall VAMC range of 11.3-16.8%. Undergoing different forms of low-value care for the same condition was weakly, but significantly, correlated for uncomplicated syncope ($\text{Rho } 0.21, p<0.019$) but not headache ($\text{Rho } 0.13, p=0.157$).

CONCLUSIONS: In a national random sample of Veterans, we identified 2 to 5-fold variation in the use of low-value diagnostic testing for 4 common conditions across VAMCs, after adjusting for differences in patient and VAMC characteristics. Veterans' receipt of low-value diagnostic testing for headache and syncope was weakly correlated within VAMCs. These findings highlight the importance of further characterizing the degree to which Veteran and facility-level factors drive these variations as a first step in developing facility-specific policies to mitigate the provision of low-value care.

LOW-VALUE PROSTATE CANCER SCREENING WITHIN THE VETERANS HEALTH ADMINISTRATION

Thomas R. Radomski^{1, 2}; Yan Huang¹; Seo Young Park¹; Carolyn T. Thorpe²; Joshua M. Thorpe²; Michael J. Fine^{2, 1}; Walid F. Gellad^{2, 1}.

¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #3182875)

BACKGROUND: Prostate specific antigen (PSA) screening for prostate cancer is of low value in men with a limited lifespan. Because most patients managed in the Veterans Health Administration (VA) are older males, low-value PSA screening in VA is likely to be common and expose Veterans to excessive costs and unnecessary risks without measurable benefits. Our objective was to quantify the frequency and variation of low-value PSA screening across VA Medical Centers (VAMCs).

METHODS: We examined a national 20% random sample of Veterans aged 75 using VA data from fiscal years (FY) 2014-2015. Using a claims-based algorithm originally developed for use in Medicare, we defined low-value PSA screening as screening among men aged 75 without a history of prostate cancer. We calculated rates of low-value PSA screening in FY15 by VAMC, adjusting for sociodemographic and VAMC-level factors from FY14. We characterized variation across VAMCs using the adjusted median odds ratio (OR). We divided VAMCs into deciles of low-value PSA screening and calculated the adjusted OR of undergoing low-value screening for Veterans within each decile. To increase the specificity of our claims-based algorithm, we determined the prevalence of low-value PSA screening after excluding Veterans who underwent prostatectomy, had a prior PSA elevation, or had a clinical reason for PSA testing, such as hematuria. In subgroup analyses, we assessed the frequency of low-value PSA screening in Veterans at greatest risk of mortality based on a Gagne Comorbidity Index Score 3.

RESULTS: Among 214,480 Veterans aged 75 who received care in 127 VAMCs, 37,866 (17.7%) received low-value PSA screening, with adjusted VAMC rates ranging from 3.3% - 38.2%. The adjusted median OR was 1.88, meaning the median odds of receiving low-value PSA screening would increase by 88% were a Veteran to transfer his care to a VAMC with more low-value testing. Veterans at VAMCs in the top decile had an adjusted OR for receiving low-value PSA screening of 12.9 (CI 11.0-15.2) compared to those in the lowest decile. After excluding Veterans with a prior prostatectomy, PSA elevation, or acute symptoms, 31,556 (14.7%) received a low-value PSA test, ranging from 2.0% - 49.9% across VAMCs. Among Veterans with the greatest comorbidity burden (n=23,377), 3,496 (15.0%) received a low-value PSA screening test (1.7% - 46.3% across VAMCs).

CONCLUSIONS: In a national cohort of older Veterans, more than 1 in 6 received low-value PSA screening, with greater than 10-fold variation across VAMCs. The frequency of low value PSA screening remained high even among Veterans without a clinical indication for testing and in those with the clearest limit to life expectancy. The overall prevalence and degree of VAMC-level variation we observed highlights the need to accurately identify and accounting for unique VAMC-level factors when developing interventions to mitigate the provision of low-value care.

LOW-VALUE PROTON PUMP INHIBITOR PRESCRIPTIONS AMONG OLDER ADULTS AT A LARGE ACADEMIC HEALTH SYSTEM

Michelle Chong¹; Folasade May¹; Katherine L. Kahn²; Edgar Corona¹; Liu Yang¹; Margaret M. Mongare¹; Vishnu Nair¹; Eric Esrailian¹; Catherine Sarkisian³; John N. Mafi^{2, 4}. ¹David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA; ²David Geffen School of Medicine at UCLA, Los Angeles, CA; ³UCLA and Greater Los Angeles VA, Los Angeles, CA; ⁴RAND Corporation, Santa Monica, CA. (Control ID #3184539)

BACKGROUND: Proton pump inhibitor (PPI) drugs are associated with complications such as pneumonia or fractures. Older adults are particularly vulnerable to complications from long-term PPIs, which can also exacerbate polypharmacy and financial toxicity. In this context, we sought to characterize the prevalence of low-value PPI prescriptions among older adults, in order to inform a future randomized-controlled quality improvement (QI) intervention.

METHODS: We created a cohort of patients aged 65 years receiving primary care at a large academic health system. Using electronic health record data, we identified patients prescribed any PPI. A multidisciplinary team (geriatrician, gastroenterologist, QI expert, two general internists) created evidenced-based criteria for appropriate vs low-value PPI prescriptions based on clinical guidelines and effectiveness literature. Supervised by a gastroenterologist and internist, an internal medicine resident conducted a manual chart review in a random sample of 100 patients prescribed a PPI to obtain demographic and clinical data. Specifically, we determined the reason for starting a PPI, duration of PPI use, whether the patient was taking the PPI, and the indication for long-term use (>8 weeks) to assess whether the prescription was appropriate. Prescriptions were considered appropriate if we could identify any guideline-based indication for long-term use, and low-value otherwise. For example, if a patient had a diagnosis of Barrett's esophagus then a long-term PPI prescription would be considered appropriate; in contrast, if a patient continued a long-term PPI without a guideline-based indication and had no documented attempt to wean or discontinue, the prescription would be considered potentially low-value.

RESULTS: Among the 69,352 older adults in our cohort, 12.6% were prescribed a PPI. Of the sample of 100 patients prescribed a PPI, 59% were female, 67% were White, and median age was 76. The 3 most common reasons for starting a PPI were uncomplicated GERD (63%), atypical GERD (7%), and peptic ulcer disease (7%). Four patients were not taking the PPI and were excluded from appropriateness assessment, and the rest (n=96) were documented to be taking a long-term PPI. Of these, 30 (31%) did not have a documented indication for long-term use, suggesting a low-value prescription. Most often (n=19), a physician would initially prescribe a PPI for uncomplicated GERD (without a long-term indication) but would not attempt to wean or discontinue the PPI over time. The remaining 69% (66/96) of patients prescribed a long-term PPI had a guideline-based indication: peptic ulcer disease prophylaxis (56), erosive esophagitis (3), Barrett's esophagus (5), and esophageal stricture (2).

CONCLUSIONS: Physicians prescribed PPIs in one in eight older adults, and nearly one third of these prescriptions were potentially low-value. These findings represent an important opportunity for targeted interventions to improve quality, lower spending, and reduce patient harm.

LUNG CANCER SCREENING: THE VIEWS OF PHYSICIANS

Celia P. Kaplan^{1, 1}; Margaret Lowenstein^{2, 3}; Maya Vijayaraghavan^{1, 1}; Judith M. Walsh^{1, 1}; Leah S. Karliner^{1, 1}. ¹University of California, San Francisco, San Francisco, CA; ²Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; ³Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA. (Control ID #3185122)

BACKGROUND: Lung cancer is the leading cause of cancer death in the U.S. Screening high risk individuals with low dose CT (LDCT) reduces mortality and is recommended by the United States Preventive Services Task Force (USPSTF). The USPSTF and the Centers for Medicare and Medicaid Services recommend that eligible patients, together with their physicians, weigh benefits with limitations and risks to make an informed decision about whether or not to be screened. Little is known about the uptake of LDCT and shared decision-making with primary care physicians (PCPs). The goals of our study were to assess the practices, barriers, and facilitators of lung cancer screening among PCPs.

METHODS: California internal and family medicine PCPs were randomly selected through the American Medical Association Physician Masterfile. We conducted a self-administered (online or paper) survey between September 2017 and May 2018 and collected additional physician demographic information through the California State Licensing Board. The survey covered the following domains: physician's lung cancer screening practices, barriers and facilitators, perceived patients' barriers to lung cancer screening, and potentially useful tools to promote lung cancer screening.

RESULTS: Of the 886 selected participants, 368 (42%) completed the survey. Over half of the respondents were female (54.4%) and 42% were

general internists. 11.8% of the physicians were Latino, 2% African American, and 37.7% Asian. Three-quarters of physicians reported offering patients lung cancer screening in the prior year (76.3%). Only 35% correctly reported the recommended ages for initiation of lung cancer screening, and 56.6% reported the correct age for discontinuation of screening. The two considerations most frequently cited when offering lung cancer screening were the potential mortality benefit and patient screening preference (75.4% and 71.8%, respectively). Most PCPs reported always discussing smoking cessation (94.6%) and lung cancer risk factors (89.8%) in relation to screening. With respect to lung cancer screening discussion barriers for physicians, the most frequently cited factor was the complexity of the visit (42.1%). Concern about cost was the most frequently reported physician-perceived barrier to screening for patients (34.9%). PCPs identified online shared decision-making tools integrated into the electronic health record as the most potentially useful counseling aid (66.7%).

CONCLUSIONS: Our results reveal that while many PCPs offer lung cancer screening and discuss lung cancer risk and smoking cessation, there are significant knowledge gaps about screening recommendations. The most significant barriers to discussing lung cancer screening largely related to visit complexity and patient counseling, suggesting the need for EHR-based tools with easy integration into workflow in the primary care setting.

MAJOR CARDIOVASCULAR OUTCOMES AMONG AT-RISK HIGH-DEDUCTIBLE HEALTH PLAN MEMBERS

James F. Wharam²; Fang Zhang²; Adrian F. Hernandez¹; Christine Lu²; Xin Xu²; Jamie Wallace²; Dennis Ross-Degnan²; Joseph P. Newhouse³.

¹Duke University, Durham, NC; ²Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; ³Harvard Medical School, Boston, MA. (Control ID #3184469)

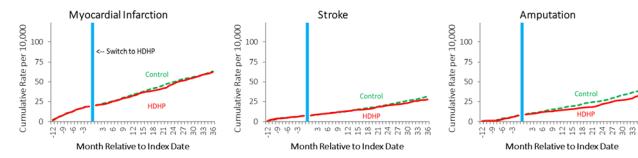

BACKGROUND: The effect of high-deductible health insurance on major cardiovascular outcomes is unknown.

METHODS: We studied a 2004-2014 national sample of 63,363 high-deductible health plan members aged 40-64 years with diabetes, cardiovascular disease, hypertension, or hyperlipidemia, who were continuously enrolled for 1 year in a low-deductible (\$500) plan followed by 3 years in a high-deductible health plan (\$1000) after an employer-mandated switch. We matched high-deductible health plan members to 539,445 contemporaneous controls who had the same cardiovascular risk factors and whose employers offered only low-deductible plans. Using a controlled interrupted-time-series design, we analyzed cumulative rates of myocardial infarction, stroke, and amputation. We modelled weighted cumulative event rates using aggregate-level segmented regression.

RESULTS: High-deductible health plan members experienced no detectable absolute change in myocardial infarction (-0.9 events per 10,000 members, 95% confidence interval: -2.7, 0.8) after 3 years of follow-up relative to the end of the baseline year compared to controls. Stroke and amputation declined by 3.4 (-4.0, -2.9) and 6.7 (-9.0, -4.4) events per 10,000 members, respectively, among high-deductible health plan members versus controls over the same period.

CONCLUSIONS: At-risk patients who were switched to high-deductible health plans did not experience increases in major cardiovascular outcomes over 3 follow-up years relative to similar members in low-deductible plans.

Figure: Cumulative rates of myocardial infarction, stroke, and amputation among at-risk HDHP and control group members.

MAKING CONNECTIONS: NATIONWIDE IMPLEMENTATION OF VIDEO TELEHEALTH TABLETS TO ADDRESS ACCESS BARRIERS IN VETERANS

Donna M. Zulman^{1, 2}; **Josephine Jacobs**³; **Cindie Slightam**²; **Amy J. Gregory**²; **Tolessa Gurmessa**²; **Rachel Kimerling**^{2, 4}; **Daniel Blonigen**²; **Emily Wong**²; **John Peters**⁵; **Leonie Heyworth**^{6, 5}. ¹Stanford University, Stanford, CA; ²VA Palo Alto Health Care System, Menlo Park, CA; ³VA Health Economics Resource Center, Menlo Park, CA; ⁴VA National Center for Post-Traumatic Stress Disorder, Menlo Park, CA; ⁵VA Office of Connected Care/Telehealth Services, Washington, DC; ⁶VA San Diego Healthcare System, La Jolla, CA. (Control ID #3180392)

BACKGROUND: In 2016, the VA launched an initiative to distribute video telehealth tablets to Veterans with health conditions, socioeconomic challenges, and geographic constraints that impede access to VA services. We sought to evaluate the implementation and effectiveness of this tablet distribution initiative.

METHODS: In a mixed methods evaluation guided by the RE-AIM framework, we examined the distribution and usage rates of 5,000 VA-issued tablets shipped in 2016 and 2017. We characterized tablet recipients in terms of sociodemographics (i.e., age, sex, race/ethnicity, rural/urban status, distance to VA facility), chronic conditions, and health care utilization. We evaluated patient experience through a survey of tablet recipients upon tablet receipt (n=2,120 respondents, response rate 61%) and after approximately 6 months of tablet use (n=1,232 respondents, response rate 61%). Given high rates of mental illness among tablet recipients, we conducted a retrospective matched cohort analysis to assess how tablet receipt was associated with mental health care utilization, continuity of care, and clinical efficiency outcomes. We also examined implementation of tablet distribution through a survey of 68 facility telehealth coordinators and interviews with telehealth coordinators and regional leadership (n= 20).

RESULTS: 89 VA facilities, spanning all 18 geographic regions, distributed tablets to 6,742 patients. Tablet recipients had an average age of 56 years, 53% lived in rural areas, 75% had a diagnosed mental illness, and almost half had six or more chronic conditions. Approximately 4 in 5 tablet recipients used the tablet during the evaluation period; 65% of video encounters were for mental health care; 10% for spinal cord injury; the remaining were for primary care, palliative care, rehabilitation, and other services. Among patient survey respondents, over 6 months there was an increase in the proportion who reported getting convenient care (67% to 80%), and many reported that the tablets saved them time (90%), money (89%), and helped them get care they couldn't otherwise (56%). For Veterans with mental health conditions, relative to the matched control group, tablet recipients experienced an increase of 1.94 (SE, 0.27) psychotherapy encounters, 1.21 (SE, 0.07) medication management visits, and an 18.5% point (SE, 0.02) increase in their likelihood of meeting the VA quality metric for mental health care continuity in the six months post-tablet receipt. Telehealth staff reported that the most common barriers to tablet distribution were insufficient training (59%), staffing shortages (55%), and provider disinterest (33%).

CONCLUSIONS: VA's initiative to distribute video telehealth tablets to high-need patients reached many individuals with social and clinical access barriers, and had a positive impact on access to mental health care and patient experiences. Additional research is needed to understand the barriers and needs of the one in five tablet recipients who did not use their tablets.

MAKING IT EASIER TO GET EVIDENCE INTO PRACTICE: AHRQ EVIDENCE-BASED PRACTICE CENTERS' (EPC) PILOT PROJECTS

Celia V. Fiordalisi¹; **Allison Schmidt**¹; **Martha Gerrity**¹; **Stephanie M. Chang**²; **Amanda Borsky**²; **Lisa Hartling**³; **Thomas Trikalinos**⁴; **Gillian Sanders-Schmidler**⁵; **Mary Butler**⁶; **Emilia Flores**⁷; **C. Michael White**⁸; **Jennifer S. Lin**⁹; **Lisa V. Rubenstein**¹⁰; **Meera Viswanathan**¹¹; **Annette M. Totten**¹²; **Karen Robinson**¹³; **Jeanne-Marie Guise**¹. ¹Portland VA Research

Foundation, Portland, OR; ²Agency for Healthcare Research and Quality, Rockville, MD; ³University of Alberta Evidence-based Practice Center, Edmonton, AB, Canada; ⁴Brown University Evidence-based Practice Center, Providence, RI; ⁵Duke University Evidence-based Practice Center, Durham, NC; ⁶University of Minnesota Evidence-based Practice Center, Minneapolis, MN; ⁷ECR Institute-Penn Medicine Evidence-based Practice Center, Plymouth Meeting, PA; ⁸University of Connecticut Evidence-based Practice Center, Storrs, CT; ⁹Kaiser Permanente Research Affiliates Evidence-based Practice Center, Portland, OR; ¹⁰RAND Corporation Evidence-based Practice Center, Santa Monica, CA; ¹¹RTI International—University of North Carolina (UNC) Evidence-based Practice Center at Chapel Hill, Chapel Hill, NC; ¹²Pacific Northwest Evidence-based Practice Center, Portland, OR; ¹³Johns Hopkins University Evidence-based Practice Center, Baltimore, MD. (Control ID #3184508)

BACKGROUND: The Agency for Healthcare Research and Quality (AHRQ) Evidence-based Practice Centers (EPCs) produce rigorous and comprehensive systematic reviews to inform health care practice and policy. It is well-known that there is a gap in translating evidence into practice. EPCs conducted a series of pilot projects to develop novel translational products with the aim of increasing accessibility and usability of evidence in healthcare systems.

METHODS: EPCs partnered with a variety of healthcare systems stakeholders, to develop and pilot translational products intended to facilitate the uptake and implementation of evidence from EPC reports. EPCs evaluated their own translational products using various methods, including conducting interviews with health systems stakeholders, such as leadership, frontline staff, and patients. We analyzed and summarized findings across these pilot projects using three sources of information: qualitative narrative from each project, structured feedback provided via a standardized reporting form, and discussions during meetings.

RESULTS: The EPCs' nine translational products generally fell into three categories: dissemination products, interactive data visualizations, and implementation products. Dissemination products summarized results from systematic reviews and required on average 57 hours to develop (range: 20-90 hours). Interactive data visualizations used technology or software to enable an interactive interface with findings of reports and required on average 152 hours to develop (range: 55-300 hours). Implementation products help health systems implement evidence into practice, and required on average 1,077 hours to develop (range: 50-2850 hours). Products were reported to be useful when they presented important information in a concise format (graphical displays of information, tables, and 3-page summaries), allowed users to explore data relevant to them (interactive displays that could drill down to study level), provided contextual information for implementation, and/or could be directly implemented into electronic medical records or clinical care processes. Products were not found to be useful if they presented information on a topic that was not a priority or for an issue that was not pertinent/relevant to the health system at that time.

CONCLUSIONS: In the fast-paced complex environment of healthcare delivery, translational products that summarize the key elements of systematic reviews may improve health system and providers' access to evidence. Translational products should prioritize clear writing, meaningful tables and graphs, and tailor the evidence to the needs of the user. The EPC Program will continue these efforts in hopes to improve healthcare system's access to high-quality, unbiased evidence that can ultimately improve quality of care and promote evidence-based medicine.

MAKING THE HIDDEN MORE TRANSPARENT: A QUALITATIVE ANALYSIS OF MEDICAL STUDENTS' ENCOUNTER LOGS TO IDENTIFY THE SOCIAL DETERMINANTS OF HEALTH LIMITING OPTIMAL CARE

David Basile; **Jed Gonzalo**; **Deanna Dubots**. Penn State College of Medicine, Hershey, PA. (Control ID #3185884)

BACKGROUND: Health care delivery and health service research focuses on disease-related issues. However, increasing evidence suggests the social determinants of health (SDH) are directly associated with patient outcomes, but these factors are typically "hidden," and infrequently identified. This qualitative analysis explored the prevalence of a pre-determined set of SDH experienced by a population of patients identified as "high risk" within one health system.

METHODS: All 1st-year medical students at Penn State College of Medicine serve as student patient navigators, working in interprofessional care teams and linked with patients who are identified as high risk. Following encounters, students complete detailed logs, addressing questions related to patient barriers and activities performed. A qualitative analysis of log data was performed using deductive and inductive techniques; a set of 22 SDH-related diagnostic codes was used (deductive) to investigate prevalence of each across all patients with reflexivity to identify potential codes (inductive) not within this pre-determined set. Two investigators performed the analysis (using NVIVO12 for data management), which involved independent coding and regular adjudication sessions.

RESULTS: A preliminary analysis of 300 logs related to 176 unique patients was performed, with the identification of 40 unique SDH codes. The five most-commonly identified SDH codes were: behavioral and mental health (7.2%), health system coordination (7.2%), transportation issues (6.7%), elderly or disability (6.3%), and lifestyle quality (6.0%). The three least-commonly identified SDH codes were: poverty (0%), poor neighborhood composition (0.1%), and cultural barriers (0.1%).

CONCLUSIONS: These preliminary data help facilitate transparency regarding the often unforeseen SDH factors that may be placing patients at risk for poor health outcomes. Factors such as care coordination, transportation, and lifestyle are less easily obtained through available methods, such as electronic health records or provider-based intake assessments. These results merit a re-evaluation in population health initiatives aimed at uncovering these barriers to improve care. Further screening by nurses and physicians for SDH needs to occur to allow for better points of care for patients. These codes can be utilized to help further achieve the goals of the Triple Aim in optimizing healthcare.

MARIJUANA USE AND RISK OF CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

Mehrzad Ghasemiesfe⁴; Salomeh Keyhani³; Brooke Barrow¹; Samuel Leonard⁴; Deborah R. Korenstein^{1, 2}. ¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Weill Cornell Medical College, New York, NY; ³University of California at San Francisco, San Francisco, CA; ⁴San Francisco VA Medical Center, San Francisco, CA. (Control ID #3177620)

BACKGROUND: Marijuana is the most widely used illicit substance in the United States; use is rising. Marijuana smoke shares carcinogens with tobacco smoke, and tetrahydrocannabinol (THC) from marijuana may have immunomodulatory effects that could lead to cancer. Rising marijuana use raises concerns about increases in the risk of developing cancer. We conducted a systematic review and meta-analysis to assess the effects of marijuana use on development of smoking-related (lung, head and neck, and urogenital) and other cancers.

METHODS: We searched 5 databases (PubMed, EMBASE, PsychINFO, MEDLINE and Cochrane Library) from January 1st, 1973 to June 11th, 2018. Two reviewers independently screened all titles and abstracts for inclusion and reviewed all observational and experimental full-text articles. We included studies in English, involving adults with 1 joint-year or more cumulative use (defined as "ever use") of marijuana, which reported development of cancer. Study characteristics and quality were assessed by 3 reviewers independently; strength of evidence for each outcome was graded by consensus. We conducted meta-analyses when there were 2 or more studies of the same design without high risk of bias (ROB), and when heterogeneity was low or moderate. In meta-analyses,

we used random-effects models to calculate summary risk ratios with 95% CIs. Narrative synthesis was performed when meta-analysis was not possible.

RESULTS: We included 24 studies (18 case-control, 5 observational and 1 cross-sectional). Among case-control studies (n=2), ever use of marijuana was not associated with head and neck squamous cell carcinoma (HNSCC) (RR= 1.15, 95% CI 0.92 - 1.45, p=0.23, I²=56%) or oral cancer (RR= 1.14, 95% CI 0.93 - 1.40, p=0.20, I²=58%). However, > 8 joint-years of use was associated with an increased risk of HNSCC (RR= 2.20, 95% CI 1.07 - 4.50, p=0.03, I²= 81%). Pooled analysis of moderate ROB case-control studies (n=3) demonstrated that ever use of marijuana was not associated with developing testicular germ cell tumor (TGCT) (RR= 1.07, 95% CI 0.87 - 1.30, p=0.52, I²=60%) compared to never- use, but > 10 joint-years use was associated with TGCT (RR= 1.18, 95% CI 1.00 - 1.40, p=0.05, I²=0%), and non-seminoma TGCT (RR= 1.51, 95% CI 1.17 - 1.96, p<0.01, I²=0%). One prospective study found increased risk for lung cancer in marijuana smokers over a long follow-up period. Findings from 5 case-control studies of lung cancer were mixed; interpretation was limited by poorly described marijuana exposure, limited results on marijuana-only users, and low levels of exposure.

CONCLUSIONS: Low-strength evidence suggests smoking marijuana is associated with development of HNSCC and TGCT. Evidence on the association between marijuana use and other cancer types is insufficient. Long term studies in marijuana-only smokers are needed to better understand the effect of marijuana use on the development of lung, oral, and other cancers.

MARKOV DECISION ANALYSIS OF THE COST-UTILITY FOR ANTICOAGULANT THERAPY IN PATIENTS WITH ATRIAL FIBRILLATION AT RISK FOR FALLS

Eric K. Wong^{1, 2}; Christina Kosar^{3, 1}; Harindra Wijeyasundera^{1, 4}. ¹University of Toronto, Toronto, ON, Canada; ²Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada; ³The Hospital for Sick Children, Toronto, ON, Canada; ⁴Sunnybrook Health Sciences Centre, Toronto, ON, Canada. (Control ID #3185508)

BACKGROUND: Atrial fibrillation (AF) is a common cardiac condition in older adults that results in an increased risk of stroke. Anticoagulants decrease stroke risk associated with AF but increase bleeding risk. Older patients are often at high risk of falls, which further compounds bleeding risk. The purpose of this study was to determine the most cost-effective anticoagulant for older adults with AF at high risk of falling.

METHODS: A Markov cohort model was used to evaluate pharmaceutical options including aspirin, warfarin, and direct oral anticoagulants (DOACs; apixaban, edoxaban, dabigatran, rivaroxaban). The base case was a 70-year-old man with recently diagnosed AF and a fall in the last 12 months. The model used the Ontario (Canada) public payer perspective and a lifetime horizon. Outcomes included life years (LY), quality-adjusted life years (QALY), costs and incremental cost-effectiveness ratios (ICERs). One- and two-way sensitivity analyses were also conducted to evaluate model robustness.

RESULTS: The use of DOACs (11.81-12.01 LY) led to longer life expectancy than ASA (10.07 LY) and warfarin (10.94 LY). When utilities were included, DOACs (10.49-10.88 QALYs) remained superior to ASA and warfarin (8.61 and 9.72 QALYs respectively). The lowest lifetime cost was for apixaban at C\$207,249.42, which was lower than both ASA and warfarin (C\$217,071.45 and C\$209,031.26, respectively). Apixaban and dabigatran were the dominant strategies after evaluation of ICERs. Apixaban was the most cost-effective strategy as dabigatran had an ICER of C\$98,725.00/QALY, which was above the cost-effectiveness threshold (C\$50,000/QALY).

CONCLUSIONS: Apixaban is the most cost-effective anticoagulant in older individuals at high risk of falls from a public payer perspective. Apixaban had the lowest total lifetime cost compared to other anticoagulants.

MD AWARE: QUALITATIVELY MEASURING THE IMPACT OF LONGITUDINAL RESILIENCY CURRICULUM AND WELLBEING SELF-ASSESSMENT TOOL AMONG MEDICAL STUDENTS

Kelly Crotty^{1, 2}; Annie Robinson¹; Colleen Gillespie³; Verity Schaye⁴; Katie Grogan⁴; Linda Tewksbury⁴. ¹NYU, New York, NY; ²Department of Veterans Affairs, New York, NY; ³NYU School of Medicine, Brooklyn, NY; ⁴NYU School of Medicine, New York, NY. (Control ID #3163076)

BACKGROUND: To bolster medical student wellbeing and combat burnout, the NYU School of Medicine (NYUSOM) implemented a longitudinal resiliency curriculum coupled with a wellbeing self-assessment tool. We qualitatively studied the impact of this curriculum on knowledge, self-awareness, and behaviors related to wellbeing and resiliency.

METHODS: The MD AWARE curriculum was launched in August 2017 for the NYUSOM class of 2020. Six sessions were implemented at critical junctures of their training. Each session includes a short lecture, followed by a small group activity led by trained facilitators. At the start of each session, students complete an anonymous online self-assessment adapted from three validated assessment tools measuring different aspects of wellbeing and burnout. Students immediately receive scores with explanations and benchmarks of each and then debrief in their small group. After each MD AWARE session, students completed a retrospective pre/post evaluation survey. Focus Groups (FG) were held in December 2017 (after Sessions 1&2) to gain richer insight into the impact of the curriculum and self-assessment tool. A purposeful sampling strategy with maximal variation was employed to recruit participants; 10 students participated in each FG. Qualitative data was gathered through the surveys and the FG. The FG were recorded and transcribed. Each FG had 2 project staff members and post-session debriefing. Member-checking was also used. Responses were subsequently coded and analyzed by two experienced faculty members (a third colleague assisted in theme triangulation). An iterative data analysis strategy was applied. Throughout the analysis, an audit trail, frequent memo writing and a reflexivity journal was maintained.

RESULTS: Themes: Community Building: *Connecting with another student...it was helpful for my wellbeing* Skill and Knowledge Acquisition and Application: *The main sort of takeaway is you need to be aware of (Burnout) and if you need help there are resources* Importance of Faculty Development: *I think that a prep session between those who designed the curriculum and those who facilitate the small-groups could go a long way towards creating the environment I imagine was originally intended* Value of Refection: *The score didn't add much...It was more about the act of answering the questions than the number that came out of it* NYU Administration Values Medical Student Wellbeing: *Just the fact that NYU has this program and is making it part of orientation already speaks volumes about its priorities: that we matter*

CONCLUSIONS: Thematic analysis of the impact of MD AWARE indicated that it provides concrete information on resources available to the students. Additionally, the students value both protected time with their peers and for self-reflection. Lastly, although care must be taken in selecting faculty to facilitate the small groups, the mere existence of the longitudinal curriculum signaled that the NYUSOM administration values medical student wellbeing.

MEANS SAFETY DISCUSSIONS FOR SUICIDE PREVENTION IN PRIMARY CARE: VETERAN AND VETERANS HEALTH ADMINISTRATION (VHA) PRIMARY CARE TEAM PERSPECTIVES

Khaya D. Clark²; Martha Gerrity^{1, 7}; Emily Kenyon²; Elizabeth Karras^{3, 4}; Joseph A. Simonetti^{5, 6}; Steven Dobbscha^{2, 7}. ¹VA Portland Health Care System, Portland, OR; ²Department of Veterans Affairs, Portland, OR; ³Center of Excellence for Suicide Prevention (VA), Canandaigua, NY; ⁴University of Rochester, Rochester, NY; ⁵Veterans Health Administration, Aurora, CO; ⁶University of Colorado School of Medicine, Aurora, CO; ⁷Oregon Health & Science University, Portland, OR. (Control ID #3180699)

BACKGROUND: Means safety (MS) counseling approaches have been developed in an effort to reduce deaths by firearms and other suicide methods. During MS (also known as lethal means) counseling, a clinician encourages the patient to limit access to potentially lethal means in case of a crisis or until the patient is no longer at elevated risk. While MS counseling can be delivered in any setting, it is time-intensive and rarely delivered in primary care. However, primary care is a critical place to intervene. Half of patients who die by suicide are seen in primary care in the month prior to death. We are developing a training program to facilitate brief MS discussions between primary care teams and Veterans with elevated suicide risk. The aim of this project was to identify main themes and language important in discussing MS with Veterans.

METHODS: This project was conducted at a large VHA Medical Center in the Pacific Northwest, and designated a quality improvement project by the institution. Four listening sessions were conducted with Veterans (n=70) and four with primary care providers (PCPs), nurses, and other staff at clinics (n=70) to understand stakeholder experiences with MS conversations and assess feasibility of staff discussing MS with Veterans in practice. Additional individual interviews were conducted with six Veterans and five PCPs. A grounded theory approach was used to analyze transcribed notes from the sessions.

RESULTS: Veteran and staff agreed that discussing means safety in primary care is appropriate and important, and may be beneficial for patients with elevated suicide risk. Staff felt that use of a team approach to MS discussions would be optimal due to competing demands on PCPs. Veterans supported a team approach since nurses or other staff may have greater rapport and contact with them than PCPs. Veterans and staff felt there were opportunities to link MS discussions with VHA's emerging Whole Health prevention approach. Both groups felt that asking Veterans directly about firearm ownership ("do you own a firearm") is not an effective strategy for initiating MS conversations because it is a sensitive topic and may be perceived as a potential threat to 2nd amendment rights. Indeed, Veterans acknowledged that they may not truthfully disclose firearms ownership, especially in the context of PCPs raising mental health concerns. Veterans reported they would feel more comfortable with MS conversations if 1) the rationale for discussing firearms in the context of a medical visit was provided; 2) they understood legal consequences of disclosure; and 3) the conversation was personalized, good eye contact was made, and staff refrained from documenting in the record during the conversation.

CONCLUSIONS: The findings suggest that training primary care teams to discuss MS with their patients is feasible. Primary care staff and Veterans have similar perspectives regarding MS which may enhance patient acceptance and usefulness of MS discussions.

MEASURING AND ANALYZING THE PERSONAL MEDICATION FORMULARY SIZE OF PRIMARY CARE PHYSICIANS

William L. Galanter^{1, 1}; Jennie B. Jarrett¹; Diana E. Norwich^{2, 3}; Maria Mirica³; Diane L. Seger^{3, 10}; Julie Fiskio³; Tewodros Eguale^{4, 3}; Alejandra Salazar³; Walid F. Gellad^{5, 6}; John P. Cashy⁵; Jennifer A. Hale⁵; Jeffrey A. Linder⁷; Bruce Lambert⁸; Suzanne Falck⁹; Lynn A. Volk¹⁰; Gordon D. Schiff^{3, 11}. ¹University of Illinois at Chicago, Chicago, IL; ²Tufts University School of Medicine, Boston, MA; ³Brigham and Women's Hospital, Boston, MA; ⁴MCPHS University, Boston, MA; ⁵VA Pittsburgh Healthcare System, Pittsburgh, PA; ⁶University of Pittsburgh, Pittsburgh, PA; ⁷Northwestern University Feinberg School of Medicine, Chicago, IL; ⁸Northwestern University, Evanston, IL; ⁹University of Illinois Hospital and Health Sciences System, Chicago, IL; ¹⁰Partners HealthCare System, Somerville, MA; ¹¹Harvard Medical School, Boston, MA. (Control ID #3185286)

BACKGROUND: Prescribing decisions are fundamental to patient care and are responsible for substantial cost, harm, and benefit. Thus, variations in prescribing warrant scrutiny. As part of a large project analyzing prescribing practices at four institutions (Partners HealthCare System (PHS), Northwestern Medicine, University of Illinois at Chicago (UIC), and the Veterans

Administration), we are profiling prescribing in the context of previously published principles of conservative prescribing. Here we present pilot data examining personal formularies of primary care physicians (PCPs) looking at the universe of drugs they initiate.

METHODS: We analyzed data from all PCPs at UIC (N=60) and a sample from PHS (N=23) totaling 226,176 prescriptions (Rx) for patients seen by those PCPs in 2016-2017. An Rx was defined as new if there was no prior Rx by any prescriber since 1/1/14. Formulary size was computed as the number of unique new drugs ordered by each physician in 2016-2017. Multivariate linear regression for UIC data were performed related to PCP panel characteristics: average age, % female, size, total visits, and PCP demographics: years since training, sex, general or family medicine.

RESULTS: PCPs started 46 \pm 18 new drugs per 100 visits. The average formulary size was 228 \pm 96 unique new drugs. Formulary size at PHS was 268 \pm 101 versus 201 \pm 92 at UIC (P=0.02). Half (49% \pm 12%) of these drugs were only prescribed once during the two-year period. At UIC, predictors of formulary size were general medicine compared to family medicine (30.8 \pm 11.9 meds, P=0.01); average panel age (16.2 \pm 5.4 fewer meds for every 10 years, P=0.004), and visits (35.3 \pm 2.3 meds when visits increased from 1500 to 2000/year, P<0.0001). PCP sex, years since training and % women in panel were not statistically significant. Comparing the average formulary at PHS and UIC, we found examples of variations in medications used. For example, oxycodone was used in 29% of new opiate Rx at PHS, but only 2% at UIC, while hydrocodone was used in 33% at UIC, but only 4% at PHS.

CONCLUSIONS: There were differences in both the size and the medications that comprised the personal formularies of PCPs at the two institutions. Roughly half of the drugs initiated were ordered only once during the two-year study period, suggesting that many PCPs are prescribing drugs for which they have limited experience in initiating. Variations in specific medication use within a class were noted and some were not evidence-based. We conclude it is feasible to compute personal formulary size at an institution level and that variability in this quantity is likely to be an important index of prescribing quality. Once known confounders such as number of visits are controlled for, comparing personal formularies between both individuals and institutions is likely to reveal important differences in prescribing patterns that may reflect variations in prescribing practices.

MEASURING PHYSICIAN WORK

Stephanie A. Eisenstat^{1, 1}; Michael Hu^{2, 1}; Walter J. O'Donnell^{1, 1}; Retsef Levi^{2, 1}. ¹Harvard Medical School, Boston, MA; ²Massachusetts Institute of Technology, Cambridge, MA. (Control ID #3182417)

BACKGROUND: With the advent of electronic health records (EHRs), a substantial portion of Primary Care Provider (PCP) time is now spent on EHR tasks such as post-visit documentation, patient communication, staff messages, results management, etc. Although these tasks represent a significant portion of PCP time, time spent is generally not accounted for in physician compensation models such as fee-for-service or panel-based payment models. The goals of this study are to 1) establish a rigorous methodology for measuring physician time spent on EHR tasks and 2) investigate variability in how EHR work is distributed temporally and across physicians, patient type and medical conditions.

METHODS: All EHR click-level data were analyzed from a primary care practice within an AMC. The analyses were performed on the EHR data from October 2018 during which the physicians touched 5,062 patients in the EHR. Using click-level timestamps for all EHR activity, we developed an objective and easily replicable method to measure the amount of EHR time spent by a physician on any individual patient or task. We also used the practice's scheduling data to determine the amount of visit time physicians are spending with individual patients. Combining this information with panel attribution labels allows us to examine the distribution of PCP EHR time across different types of patients and across the time of day. In particular, we examine the time allocation of each PCP along three dimensions: 1) patient panel attribution, 2) tasks related to patients who did and did not have a PCP

office visit and 3) whether the EHR work was performed after-hours (i.e., completed outside of the PCP's clinical scheduled bookable hours). The methods developed in this preliminary study are currently being expanded to additional primary care practices with click-level EHR data spanning 3 years.

RESULTS: Our analyses indicate that during one standard calendar month, the average PCP spent 290 hours completing EHR tasks. The average amount of time spent in office visits was 73 hours (both normalized to 1 full-time equivalent or FTE). On average, the division of total PCP EHR time spent between panel versus non-panel patients was 78% and 22%, respectively. Similarly, the division of total PCP EHR time spent on patients with and without office visits was 71% and 29%, respectively. Examining the temporal distribution of the EHR work, we observe that >40% of PCP EHR time occurred after-hours.

CONCLUSIONS: PCP work is rapidly expanding beyond traditional office visits as the prevalence and complexity of EHR tasks continues to grow. Our findings indicate that the vast majority of PCP time has shifted away from patient facing activities and instead is now focused on EHR tasks. Developing the methodology to measure and categorize this EHR work is foundational to establishing a better understanding of modern PCP work. This is particularly important as health systems explore compensation models and strategies for improving physician work and engagement.

MEASURING PRECONCEPTION WELLNESS WITHIN THE VETERANS HEALTH ADMINISTRATION (VHA)

Deirdre A. Quinn¹; Maria K. Mor¹; Florentina Sileanu¹; Xinhua Zhao¹; Lisa S. Callegari^{2, 5}; Laurie C. Zephyrin⁴; Sonya Borrero^{1, 3}. ¹VA Pittsburgh Healthcare System, Pittsburgh, PA; ²VA Puget Sound Healthcare System, Seattle, WA; ³University of Pittsburgh, Pittsburgh, PA; ⁴Department of Veterans Affairs, Washington, DC; ⁵University of Washington School of Medicine, Seattle, WA. (Control ID #3184035)

BACKGROUND: More women in the United States (U.S.) are dying in or around childbirth now than 25 years ago. Despite increased attention to preconception care, lack of consensus about implementing such care or assessing the success of preconception care has stymied progress. In 2016, the Clinical Workgroup of the National Preconception Health and Health Care Initiative proposed nine wellness measures to assess the quality of preconception care in healthcare systems. As the largest integrated health care system in the U.S., the VHA is uniquely positioned to lead the way in implementing and evaluating efforts, including preconception care, to improve birth outcomes. This study is the first comprehensive assessment of VHA's performance on measures of preconception wellness.

METHODS: We examined national administrative data, including inpatient, outpatient, and fee-basis visits (visits to non-VA providers that are paid for by VA); lab and pharmacy data; and health factors screening data for women Veterans ages 18-45 with at least one pregnancy outcome (ectopic pregnancy, spontaneous abortion, stillbirth, and/or live birth) during fiscal years 2010-2015. After identifying outcomes, we estimated last menstrual period (LMP) from gestational age at the time of the outcome and used LMP as a reference point to assess eight of the nine preconception indicators at various timepoints (e.g., 3 or 12 months prior to LMP); one indicator, pregnancy intention, was not captured in VA administrative data.

RESULTS: We identified 26,556 pregnancy outcomes from 21,234 women Veterans. Just over half (56.6%) were in non-Hispanic white women, 23.4% in non-Hispanic black women, and 10.9% in Hispanic women; the mean age at LMP was 29.8. The majority (77.1%) of pregnancies ended in live birth; 22.4% resulted in spontaneous abortion or ectopic pregnancy, and 0.5% in stillbirth. Nearly one quarter (23.7%) of pregnancies had no evidence of prenatal care; 44.4% of pregnancies had no documented tobacco use screening and 49% had no documented depression screening within 1 year prior to LMP; 29.5% of pregnancies occurred to obese women; and only 40.2% of pregnancies in women with pregestational diabetes had a documented optimal HbA1c measurement (<6.5) in the year prior to LMP. Evidence of any

STI screening in the year prior to 3 months post LMP was low, as was documentation of prenatal folic acid use; 95% of pregnancies appeared free from exposure in the year prior to LMP to medications under the Workgroup's six classes of teratogenic medications.

CONCLUSIONS: Despite the limitations of existing administrative data, monitoring standard measures of preconception wellness can provide benchmarks for improving women's health across systems and communities. Areas for intervention to improve women Veterans' preconception wellness were identified, including weight reduction, optimizing control of diabetes prior to pregnancy, and improved use and documentation of routine health screenings.

MEDICAID EXPANSION AND PERFORMANCE ON ED THROUGHPUT MEASURES

Anjali Bhatla; Jaya Aysola. University of Pennsylvania, Philadelphia, PA. (Control ID #3183592)

BACKGROUND: Emergency department (ED) throughput is a key measure of hospital performance with public reporting of ED wait times metrics since 2012. Mounting evidence reveals the effects of ED wait times on inpatient length of stay, care quality, and hospital costs. However, we lack knowledge of the effect of Medicaid expansion on ED throughput measures. This study aims to determine if there is an association between state Medicaid expansion status and statewide ED throughput measures.

METHODS: First, we determined if the number of insured significantly increased over time in Medicaid expansion states versus non-expansion states. Then, using CMS Hospital Compare data, we examined two ED throughput measures for patients admitted to the hospital: 1) the overall length of stay in the ED (ED1) as measured by the median time in minutes patients spent in the ED from their arrival to departure to inpatient floor; and 2) the boarding time (ED2), as measured by the median time in minutes patients spent in the ED from the time a provider requests a bed to departure to inpatient floor. For each metric, we used hospital-wide quarterly data, aggregated by state from 2012 to the first quarter of 2017. We conducted an interrupted time series analysis to evaluate the relationship between implementation of Medicaid expansion and ED performance metrics, as measured by quarterly average median ED wait times for Medicaid expansion states ($n=31$) and non-expansion states ($n=19$).

RESULTS: The percentage of insured individuals increased significantly ($p=0.031$) in states that expanded Medicaid. In 2012, the mean difference in ED1 between non-expansion states (241.6) and states that later adopted Medicaid expansion (281.2) was significantly different ($p<0.001$). In the first quarter of expansion, the average median total length of stay in the ED increased by 4.27 minutes in the non-expansion states, as compared to a significantly greater increase of 10.14 minutes in average median wait times among the expansion states ($p=0.01$). The average median boarding time (ED2) between non-expansion states (79.4) versus expansion states (103.7) differed significantly ($p<0.001$) in 2012. In the first quarter of Medicaid expansion, ED2 increased by 1.97 minutes ($p=0.009$) in non-expansion states, and 3.2 minutes in expansion states ($p=0.22$).

CONCLUSIONS: Since 2012, the total time spent in the ED (ED1) and boarding time (ED2) for patients admitted to the hospital have been significantly longer in Medicaid expansion states versus non-expansion states. Our findings suggest that the influx of newly insured individuals through Medicaid expansion may have increased overall length of stay in ED for patients eventually admitted to the hospital in states that expanded Medicaid but had no significant impact on their average median boarding times. Future efforts should focus on delivering low-acuity care in settings outside of the ED to improve timeliness of care for patients requiring hospital admission from the ED.

MEDICAL ASSISTANT (MA)-FACILITATED CHRONIC DISEASE AND CANCER SCREENING IN A SAFETY NET CLINIC: TWO-YEAR IMPACT OF A QUALITY IMPROVEMENT PROJECT

Kala Ghooray^{1,2}; Jenny K. Cohen³. ¹Highland Hospital, Berkeley, CA; ²UC Irvine School of Medicine, Irvine, CA; ³Highland, Oakland, CA. (Control ID #3176883)

BACKGROUND: Although screening can reduce morbidity and mortality from cancer and chronic disease, screening rates in minority and low-income populations continue to be low. Within primary care, medical assistants (MAs) play an integral role in patient education, advocacy, and routine health maintenance. We designed an intervention aimed to increase MAs knowledge and self-efficacy regarding screening through education and empowerment, with a goal of improving chronic disease and cancer screening rates.

METHODS: As part of a 2016-2018 initiative to improve screening for chronic disease and cancer at an urban county outpatient Internal Medicine clinic, MAs were given more resources and time to conduct patient outreach. We created monthly education sessions to give MAs concrete tools for teaching and patient education. Topics included vaccines, hepatitis C, diabetes, hypertension, colorectal, cervical, and breast cancer screening. Changes in MA knowledge were measured through pre- and post-surveys, and one cumulative end-of-year survey. We tracked screening order rates over the past 2 years to assess the interventions' impacts on patient care. MA knowledge and job satisfaction were assessed using surveys and a focus group.

RESULTS: 83% (15/18) MAs participated in the pre- and post-surveys. Post-test scores improved following the sessions on cervical cancer screening (pre=31%, post=55%, $p=0.06$), diabetes (pre=49%, post=72%, $p=0.10$), and CRC screening (pre=69%, post=85%, $p=0.10$), reflecting increased knowledge about who should receive cervical cancer, diabetes, and CRC screening. Between 9/16 and 11/18, there was an increase in order rates for cervical cancer screening (65.81% to 70.48%), order rates for mammograms (52.04% to 85.5%), completion rates for diabetic microalbumin/creatinine ratios (58.05% to 83.26%), and order and completion rates for FIT tests (74.98% and 60.95% to 75.54% and 62.31%). The percentage of patients with diabetes and hypertension who had their blood pressure or HbA1c well controlled also improved during this time period (59.45% and 64.41% to 77.51% and 68.35%). We solicited free-response feedback from the MAs who enjoyed the sessions and appreciated feeling a sense of professional investment. While MAs felt they had the training necessary to take on an expanded role, the added time-pressure was a challenge.

CONCLUSIONS: Our primary care redesign model focusing on MA education and empowerment improved MAs knowledge about screening and was associated with modest improvements in order rates. In addition to education, the clinic's investment in their professional skills, team role, and time was critical. Although there have been improvements in order and completion rates for all screenings being tracked, those improvements have recently plateaued. This may be due to MA turnover and changes in staffing resulting in the loss of dedicated patient-outreach time, highlighting the need for continued education and the importance of protected time for patient-outreach.

MEDICAL STUDENT EXPERIENCE WITH DIFFICULT CONVERSATIONS DURING THE ACTING INTERNSHIP

David Staudt¹; Corrie A. Stankiewicz²; Laura Dingfield³. ¹Hospital of the University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania SOM, Narberth, PA; ³University of Pennsylvania, Philadelphia, PA. (Control ID #3181403)

BACKGROUND: Internal medicine residency program directors have identified communication skills as an important competency for incoming interns.¹ Acting internships (AIs) are an opportunity for senior medical students to gain experience with higher-level communication skills prior to starting residency training. Little is known about students' experiences with difficult conversations during AIs. We surveyed students about their experience with several types of difficult conversations during their AI.

METHODS: All students (N = 105) who had completed a 4 week medicine AI at our institution in 2018 were sent a link to an electronic survey assessing their roles and attitudes with 5 potentially difficult conversations: discussions with upset patients/families, leaving against medical advice, breaking bad news, assessing code status and limiting/withdrawing life-sustaining treatments. Anonymous survey data was collected electronically via Qualtrics. Results were calculated using the total number of survey responses, including both complete and partially complete surveys.

RESULTS: Seventy-seven students completed the entire survey and 5 students submitted partial responses for a total of 82 survey responses (78% response rate). Students most frequently reported participating in code status discussions (91%) and discussions with upset patients/families (99%). A majority of students reported holding these conversations without supervision at some point during their AI (52%, code status and 74%, upset patient/family). While a majority of students reported having had training in talking with upset patients/families (83%), less than half reported having had any training in assessing code status (45%). By the end of the 4 week AI rotation, the majority of students reported confidence in their ability to independently talk with upset patients/families (74%) and to independently assess code status (58%).

CONCLUSIONS: Existing literature suggests that serial clinical exposure to code status discussions breeds false confidence without improvement in competency among residents.² Our data suggest a similar phenomenon among medical students, with many students reporting confidence in leading difficult conversations despite only a short window of exposure, minimal to no formalized training and lack of oversight. Formal programs have been shown to improve trainee competency with durability in skill set over time.^{3,4} While our data is from a single institution, it highlights a significant confidence-skill gap with regard to communication skills during critical doctor-patient interactions. The number of partial responses (n=5) might represent another limitation, although this would tend to underestimate the magnitude of a confidence-skill gap. Further exploration of these trends and resulting evidence-based curricular development that spans trainee levels are essential.

MEDICAL STUDENT PERSONALITY TRAITS AND CLINICAL GRADES IN THE INTERNAL MEDICINE CLERKSHIP

Monica Malviya¹; Rebecca B. Forman¹; Masrur A. Khan¹; Keara English¹; William Southern²; Amanda Raff³; Tulay Aksoy³. ¹Albert Einstein College of Medicine, Bronx, NY; ²Montefiore, Bronx, NY; ³Montefiore Medical Center, Bronx, NY. (Control ID #3184959)

BACKGROUND: Evaluation of clinical performance is an important component of medical students' grades in 3rd year clerkships. However, clinical evaluation is subjective and may be influenced by factors independent of clinical skills. We hypothesized that student personality traits might impact evaluator perception of clinical performance, thus impacting overall clerkship grade. Using the OCEAN personality trait scale (Openness, Conscientiousness, Extraversion, Agreeableness, Neuroticism), we examined the association of personality traits with grades in the 3rd year internal medicine clerkship at a single institution.

METHODS: 3rd year medical students enrolled in the medicine clerkship during the academic years of 2016-17 and 2017-18 responded to a questionnaire assessing their personalities in accordance with the OCEAN criteria. Student responses were linked to grade components, then de-identified data were provided to the research team for analysis. This study was deemed exempt by the Einstein Institutional Review Board. Grade components of the final clerkship grade include ward team clinical evaluations, preceptor evaluations, and NBME shelf exam score. Chi-squared and regression analyses were used to evaluate correlations between the OCEAN personality domains, individual personality traits, and clerkship grades.

RESULTS: 356 students were eligible to participate. 97 responded (27% response rate) and 94 provided information to allow linking to clerkship grades and were included in the analysis. 51 (53%) of the respondents were female, 45 (46%) male, and 1 (1%) identified non-binary. The average age was 26.4 ±

2.6. 56 (60%) received either a High Pass or a Pass, and 38 (40%) received Honors in the clerkship. An overall clerkship grade of honors was strongly correlated with a clinical performance above the median preceptor score ($p = 0.001$). No OCEAN domains correlated significantly with a final grade of honors. However, individual traits within the personality types were associated with an honors grade. "Deep thinking" correlated positively with honors ($p = 0.006$). "Shyness" correlated negatively with honors ($p = 0.054$). "Moody" was a trait that correlated positively with honors, though was not significant. Traits that suggested a trend correlating negatively with honors but did not reach significance included "depressive thinking," "reserved," "worrying," and "enthusiastic." Increasing scores in the Openness domain were correlated positively with a grade of honors (OR 1.05, $p = 0.17$).

CONCLUSIONS: Significant correlations between clerkship honors and traits of "deep thinking" (positive) and "shyness" (negative) were observed, which are in the domains of conscientiousness and neuroticism, respectively. Response bias and power were limiting factors in the overall study, and could explain why other traits or personality types did not reach statistical significance in the final analysis. Further investigations are needed to assess whether clerkship grades are impacted by personality traits.

MEDICARE'S BUNDLED PAYMENT FOR CARE IMPROVEMENT MODEL DID NOT CHANGE SKILLED NURSING DISCHARGE PATTERNS

Jane M. Zhu¹; Amol S. Navathe²; Yihao Yuan³; Sarah Dykstra²; Rachel M. Werner⁴. ¹Oregon Health and Science University, Portland, OR; ²University of Pennsylvania, Philadelphia, PA; ³University of Illinois at Chicago, Chicago, IL; ⁴University of Pennsylvania and Philadelphia VA, Philadelphia, PA. (Control ID #3185492)

BACKGROUND: One potential response to bundled payment incentives is that hospitals may more carefully select where they refer patients after discharge, in order to concentrate discharges and improve care coordination with skilled nursing facilities (SNFs). We evaluated whether participation in Medicare's voluntary Bundled Payment for Care Improvement (BPCI) model was associated with changes in discharge referral patterns to SNFs, specifically number of SNF partners and discharge concentration.

METHODS: We used Medicare claims data from 2010-2015 to identify admissions for lower joint replacement surgery and the following medical conditions: congestive heart failure, renal failure, sepsis, pneumonia, UTI and kidney infections, chronic obstructive pulmonary disease, and stroke. We identified hospitals participating in Model 2 bundles, which comprises 95% of BPCI participants, and matched hospitals based on hospital characteristics including urban/rural location, teaching hospital, hospital ownership, annual discharges to SNF, and certified bed count. Our analytic sample included 3,078 acute care hospitals and 14,866 Medicare-certified SNFs in the US, encompassing more than 47 million hospital discharges. We used difference-in-differences analyses to assess changes in discharge patterns among BPCI-participating hospitals, compared to matched control hospitals. Our two measures of hospital-SNF integration were: a hospital's *number of SNF partners*, or the number of unique SNFs to which a hospital discharged its patients for each half-year of the study period. The second was a hospital's *discharge concentration* in each half-year, based on the Herfindahl-Hirschman Index (HHI). Multivariable regression models with hospital fixed effects were estimated for each outcome and included a BPCI-hospital indicator, intervention period indicators, and the interaction between the two.

RESULTS: Of the hospitals in our sample, 416 participated in BPCI, with the majority selecting into joint replacement episodes (n=295). BPCI participation was not associated with any change in number of SNF partners (increase by 0.8 SNFs among BPCI hospitals relative to non-BPCI hospitals, 95% CI [-0.2, 1.9], $p=0.11$), or in discharge concentration (increase in HHI of 0.2 among BPCI hospitals relative to non-BPCI hospitals, 95% CI [-68.7, 69.1], $p=0.36$). Results did not vary across clinical conditions, and were robust across duration of BPCI participation and with different comparison groups.

CONCLUSIONS: BPCI participation was not associated with changes in the number of SNF partners or in discharge concentration relative to non-BPCI hospitals. Studies on bundled payment programs for lower joint replacement have demonstrated efficacy in cost containment with little adverse effects on quality, but how hospitals are achieving these results remains unclear. More research is needed to understand how hospitals are responding to bundled payment incentives and specific practices that contribute to improvements in cost and quality.

MEDICATION CONCERN PREDICT MEDICATION ADHERENCE IN LATINO PATIENTS WITH HYPERTENSION

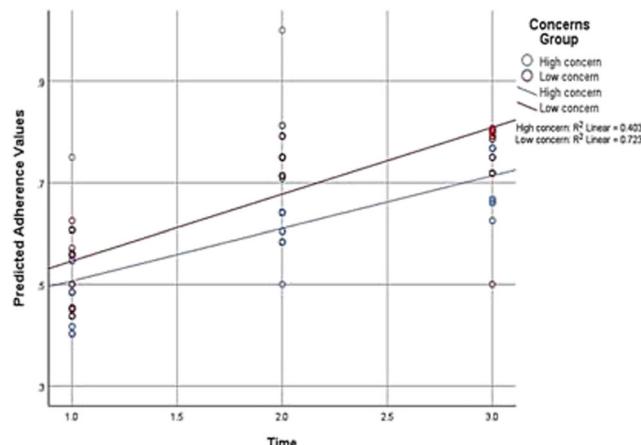

Kerstin Nolan; Mark Butler; Antoinette Schoenthaler. NYU School of Medicine, New York, NY. (Control ID #3176485)

BACKGROUND: Latinos have the lowest blood pressure (BP) control rates in the US, which may be explained by lower rates of medication adherence versus other ethnic groups. While patient medication concerns have been shown to predict poorer adherence in hypertensive patients, empirical data in Latinos is non-existent.

METHODS: This study was a secondary analysis of a randomized controlled trial in 119 Latino patients with uncontrolled BP followed in a community-based practice. Patient medication concerns were assessed with the Concerns-specific subscale of the Beliefs about Medications Questionnaire; lower scores indicate greater concerns. Medication adherence was assessed with the 8-item Morisky questionnaire; higher scores indicate better adherence. Repeated measures analysis using linear mixed effects modeling was used to evaluate whether changes in medication concerns predicted changes in adherence overtime (Baseline, 3 and 6-months). Patient characteristics (e.g., age, gender, insurance) known to influence adherence and treatment group were treated as covariates in the model.

RESULTS: The mean age was 61 years (SD:11.2); 50% were women; 38% had annual household income <\$20,000, and 59% had less than a high school degree. A majority of patients were of Puerto Rican or Dominican ancestry. At baseline, 51% (SD:16.5) of the sample reported being adherent to their antihypertensive medications; the mean score on the Concerns scale was 3.07 (SD:0.5; range:1-5). We found a significant time by concerns interaction effect on adherence in multivariate analyses ($F(2,24)=1.61$, $p=0.04$). Specifically, adherence improved at a greater rate overtime among patients that reported low medication concerns than those that reported high concern (Figure).

CONCLUSIONS: Concerns about antihypertensive medications is a potentially modifiable factor that affects adherence in Latino patients with uncontrolled BP. Interventions targeting patients' medication concerns may help to improve the low rates of adherence in this high-risk patient population.

MENTAL HEALTH AND SELF-EFFICACY TO MANAGE CHRONIC HEALTH CONDITIONS AMONG NYC PUBLIC HOUSING RESIDENTS

Susan L. Creighton¹; Jillian Diuguid-Gerber²; Katharine Lawrence¹; Milna Rufin²; Fred W. LaPolla³; Colleen Gillespie⁴; Noel Manyindo⁵; Rachel Dannefer⁵; Lois Seidl⁵; Lorna Thorpe¹. ¹NYU School of Medicine, New York, NY; ²New York University, New York, NY; ³NYU School of Medicine, New York City, NY; ⁴NYU School of Medicine, Brooklyn, NY; ⁵NYC Department of Health, New York, NY. (Control ID #3184616)

BACKGROUND: Self-efficacy to manage chronic conditions affects patients' health-related behaviors and interactions with the healthcare system and therefore influences health outcomes. Few studies have explored the complex relationships between mental health, self-efficacy, and management of chronic disease. A greater understanding of these interactions could inform successful community programming for marginalized populations such as public housing residents. Harlem Health Advocacy Partners is a community health worker (CHW) program designed to close health and social outcomes gaps in residents living in New York City Housing Authority (NYCHA). This study uses survey data collected for this initiative to explore the relationship between mental health and self-efficacy to manage chronic conditions among NYCHA residents with asthma, diabetes, and/or hypertension, and assess whether key variables such as connectedness to health care, social isolation and general health influence this relationship.

METHODS: Five NYCHA housing developments were selected for the CHW intervention with five matched developments for comparison. Four-hundred adult residents with a chronic disease were recruited. Baseline intake interviews were conducted in person. Self-efficacy for managing chronic disease was measured with a 6-question scale. Depression was assessed using PHQ9 scores, a screen for the presence and severity of depression. Difficulty with mental health was assessed with questions on how difficult mental health problems made it to do work, take care of things at home, or get along with others. Bivariate analyses were conducted to assess the relationship between mental health and self-efficacy. A hierarchical linear regression model was run with mental health and other relevant variables (selected based on availability in the dataset and theoretical significance) as independent variables and self-efficacy as the outcome variable.

RESULTS: Self-rated general health predicted the greatest amount of variance in self-efficacy (15.7%, $p < 0.001$). Mental health also contributed significantly; difficulty with mental health contributed 4.0% ($p < 0.001$) and depressive symptoms contributed 1.1% ($p = 0.03$) to the variance in self-efficacy. Other variables, including demographics, type of insurance, connectedness to a primary care provider, and social isolation, were not associated with self-efficacy. Overall, the full model explained 22.5% of the variance in self-efficacy to manage chronic conditions.

CONCLUSIONS: NYCHA residents with mental health difficulty or depression represent a uniquely marginalized subpopulation of public housing residents, and were found to have lower self-efficacy than other residents, which may mean decreased ability to self-manage chronic medical conditions. Future research should explore relationships among mental health, self-management, and health care outcomes with the goal of augmenting targeted CHW interventions.

MENTORSHIP OF UNDERREPRESENTED PHYSICIANS AND TRAINEES IN ACADEMIC MEDICINE: A SYSTEMATIC REVIEW

Eliana Bonifacino¹; Eloho Ufomata²; Amy H. Farkas³; Jennifer Corbelli².

¹UPMC, Pittsburgh, PA; ²University of Pittsburgh Medical Center, Pittsburgh, PA; ³Medical College of Wisconsin, Milwaukee, WI. (Control ID #3185553)

BACKGROUND: The US is becoming increasingly diverse from a racial and ethnic perspective; however, the physician workforce has continued to

have disproportionately low numbers of medical school graduates from racial and ethnic groups that are described as underrepresented in medicine (URiM). Mentorship has been proposed as one way to increase the recruitment, retention and experience of URiM physicians and trainees. Our objective was to identify and describe mentoring programs for URiM physicians in academic medicine and to identify barriers and facilitators to success of such programs.

METHODS: We searched PubMed, PsycINFO, ERIC, and Cochrane databases following PRISMA guidelines in June 2017. We included original publications that described a mentoring program, exclusive of mentoring for a procedural skill, which included academic physicians or trainees from URiM backgrounds, and were conducted in the US. Two reviewers independently evaluated all records for eligibility, and abstracted data from included studies.

RESULTS: Our search returned 3308 results, of which 2632 references were excluded based on title and abstract. We performed a full text review on 669 manuscripts and 32 articles met our inclusion criteria. Of those, 13 programs were specifically created for URiM participants. Nine of the programs were developed for junior faculty, seven for medical students; two for residents and none for senior faculty. Frequently cited objectives of these programs were to improve research, diversify representation in specific specialty areas and recruit and retain URiM participants. The dyadic model of mentoring was the most common, however, several novel models were described which emphasized mentorship across different training levels. Program evaluations were primarily survey-based with high satisfaction scores, although some articles reported objective outcomes including publications, retention, and promotion.

CONCLUSIONS: This review describes a range of successful mentoring programs for URiM physicians. The traditional dyad model of mentorship remains common, though novel approaches aimed at improving the pipeline are emerging. Overall, the mentorship programs are met with high satisfaction regardless of mentor demographics, and can promote improvement in academic productivity, and recruitment and retention. Our review describes many mentoring programs for URiM physicians, most of which can be readily adapted by institutions depending on their local resources and goals to help promote and URiM physicians in academic medicine.

META-ANALYSIS OF CT PULMONARY ANGIOGRAPHY YIELD IN US EMERGENCY DEPARTMENTS

Safiya Richardson¹; Anne Press²; Timothy Wigand³; Juliana A. Rosentsveig,¹; Patricia Driscoll³; Alexander O'Connell⁴; Saori Herman³; Janice Lester³; Sundas Khan³; Thomas McGinn³. ¹Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; ²NYU School of Medicine, New York, NY; ³Zucker School of Medicine at Northwell/Hofstra, Manhasset, NY; ⁴New York Presbyterian, New York City, NY. (Control ID #3185364)

BACKGROUND: Every year about 2.4 million CT Pulmonary Angiography (CTPA) scans are performed to evaluate for pulmonary embolism in Emergency Departments (ED) in the United States. Each CTPA carries a 14% risk of contrast induced nephropathy and a lifetime malignancy risk that can be as high as 2.76%. Incidental findings requiring diagnostic follow up are found in 24% of tests, increasing both costs and harms from repeat imaging. CTPA yield (percent of studies positive for PE) is a measure of appropriateness of use and has not been reviewed systematically. We conducted a systematic review and meta-analysis of CTPA yield in US EDs to establish a typical yield for our current practice environment and to determine if there have been changes to this yield over time.

METHODS: Cochrane, Embase, PubMed and Web of Science were searched as data sources. Observational cohort studies of adults were selected that measured CTPA yield in all ED patients referred for testing with clinical suspicion of PE. The titles and abstracts of studies identified by the search were independently reviewed by two reviewers. Studies were evaluated for exclusion criteria. Remaining studies were reviewed in full

text by two independent reviewers. We extracted study characteristics and CTPA yield from the remaining studies. CTPA yields were estimated using random effects models. The I2 test was used to assess heterogeneity in CTPA yields among the studies.

RESULTS: Our search identified a total of 2,746 potentially relevant articles. Of those 296 remained after title and abstract review and 31 remained after full text review. The 31 studies included in our meta-analysis included a total of 42,670 patients. These studies were divided into three time periods for which CTPA yield was calculated. For time periods 1997-2002, 2003-2007 and 2008-2013 the yields were 11% (9%, 14%), 8% (6%, 9%) and 8% (6%, 10%) respectively. The studies were heterogeneous for all calculated pooled CTPA yields ($I^2 = 82\%$, 94%, and 86% respectively).

CONCLUSIONS: This is the first study to systematically review CTPA yield in US EDs. Establishing a national benchmark for yield assists health systems seeking to monitor and increase CTPA yield as a part of quality improvement efforts. Future directions include further stratification by type of health system and analysis of non-US yields.

METRICS OF RETENTION IN HIGH-RISK POPULATIONS: DECREASING "NO-SHOW" APPOINTMENTS THROUGH BEHAVIORAL ECONOMICS

Phillip Groden; Alexandra Capellini; Erica Levine; Bernard Ortega; Sandeep Kishore. Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3162708)

BACKGROUND: Studies have shown that a minority of the U.S. population—those often disconnected from care and beset with multiple chronic conditions—accounts for a substantial portion of annual health care spending. Interventions for these high-risk populations, such as Mount Sinai's Peak Health practice, aim to improve patient outcomes while reducing overall utilization and costs. "No-show" appointments directly oppose these goals by increasing the likelihood of ED utilization, inpatient admissions, and predictors of poor health. High-risk interventions could therefore benefit from reducing no-show appointments by improving rates of patient retention. However, no standard for measuring retention exists within this setting, and reporting of retention rates across the literature for such interventions is sparse and inconsistent. Adoption of two previously reported metrics promises to capture a thorough picture of patient retention in high-risk populations: *encounter adherence* and *encounter constancy*. The application of these metrics is depicted through a study assessing the effects of a behavioral economics-based intervention on patient retention within Mount Sinai's Peak Health practice.

METHODS: The intervention consisted of specialized appointment reminder cards and clinic signage designed to improve the likelihood of successful patient encounters. At six months, appointment cards were transitioned to a computer format to promote provider adoption. *Encounter adherence*, a ratio of successful patient-provider interactions, is the number of completed encounters divided by all scheduled encounters, excluding those cancelled or rescheduled. *Encounter constancy*, a measure of consistent interactions across time, is defined as the number of 3-month intervals annually with at least one successful encounter (range=0-4), or the percentage of patients maintaining a specific constancy value.

RESULTS: At baseline, Peak Health's *encounter adherence* rate over six months was 74.7% (1282/1716); following introduction of the intervention, the *encounter adherence* rate improved over six months to 76.5% (1302/1701; $p=0.2$). At twelve months, *encounter adherence* will be compared to assess if use of the computer-based appointment reminders had an appreciable effect on retention, and *encounter constancy* will be compared to baseline to evaluate the effect of the intervention on the consistency of interactions across time.

CONCLUSIONS: Within the first six months, the behavioral economics-based intervention did not appear to significantly improve

patient retention; this could reflect low adoption of the original appointment cards by Peak Health providers or the need for a more intensive intervention to improve retention above the rates described. Utilization of the *encounter adherence* and *constancy* metrics promises to fill salient gaps surrounding patient retention in this setting, while a renewed focus on retention may provide significant short and long-term benefits for high-risk interventions.

MICROALBUMINURIA AS A MARKER TO ESTIMATE MAJOR VASCULAR EVENTS IN STROKE PATIENTS: SYSTEMATIC REVIEW AND META-ANALYSIS

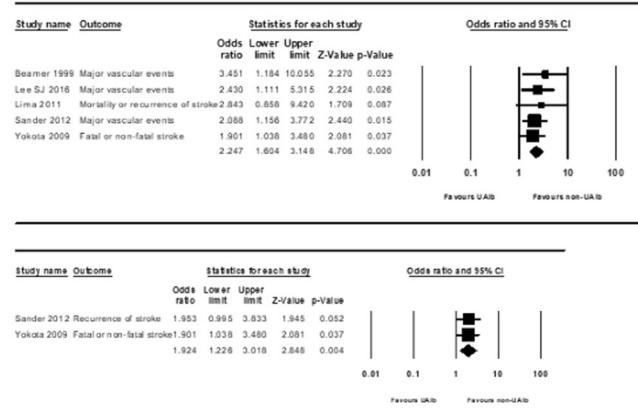

Takayuki Yamada¹; Satoshi Miyashita¹; Hayato Mitaka¹; Sera Satoi²; Svetlana Chernyavsky¹. ¹Mount Sinai Beth Israel, New York, NY; ²Nippon Medical School Hospital, Bunkyo-ku, Japan. (Control ID #3181392)

BACKGROUND: Microalbuminuria is a marker of systemic endothelial dysfunction. It is known to be associated with coronary artery disease, stroke and cardiovascular mortality. However, it remains unclear whether or not microalbuminuria is related to major vascular events in patients with stroke.

METHODS: We conducted a systematic review and meta-analysis to evaluate the effect of microalbuminuria to estimate the risk of major vascular events in patients with stroke. PubMed, EMBASE and the Cochrane Library from inception to December 2018 were searched. Studies that compared stroke patients with microalbuminuria and non-albuminuria were included. Primary outcome was major vascular events. All statistical analyses were performed using Comprehensive Meta-Analysis 3 (Biostat, Englewood, NJ, USA).

RESULTS: A total of five observational studies met the inclusion criteria. The pooled population consisted of 2,035 subjects. Microalbuminuria was associated with greater risk for major vascular events in patients with stroke (OR, 2.247; 95% CI, 1.604 to 3.148; I², 0%) (Upper figure). Subgroup analysis demonstrated that microalbuminuria was associated with greater risk for recurrent stroke in patients with stroke (OR, 1.924; 95% CI, 1.228 to 3.018; I², 0%) (Figure 2). The rank correlation did not show significant publication bias (*p*, 0.14) but Egger's test showed significant publication bias (*p*, 0.033).

CONCLUSIONS: Microalbuminuria provides good estimate of major vascular events including recurrent stroke in patients with stroke.

Upper figure: Forest plot of the association between microalbuminuria and cardiovascular events in patients with stroke. Odds ratio were presented as mean and standard deviation (SD). 95% CI confidence interval. Lower figure: Forest plot for subgroup analysis of the association between microalbuminuria and stroke in patients with stroke. Odds ratio were presented as mean and SD.

MINIMAL CLINICALLY IMPORTANT IMPROVEMENT (MCII) IN KNEE OSTEOARTHRITIS: A POST HOC ANALYSIS OF A PROSPECTIVE, RANDOMIZED CLINICAL TRIAL OF DICLOFENAC SODIUM GEL (DSG) 1%

Pamela Kushner^{1,2}; Bharat Patel³; Sandy Yacoub Garas⁴. ¹University of California, Irvine, Irvine, CA; ²Kushner Wellness Center, Long Beach, CA; ³GSK Consumer Healthcare, Weybridge, United Kingdom; ⁴GSK Consumer Healthcare, Warren, NJ. (Control ID #3146561)

BACKGROUND: The minimal clinically important improvement (MCII) is defined as the smallest change in measurement that represents patients' perceptions of what they view as an important improvement of symptoms. Thus, the MCII represents an improvement of relevance in a clinical trial or the minimal meaningful change at an individual level.(1) The objective of this post hoc analysis was to determine the number and percentage of osteoarthritis (OA) patients achieving the MCII for pain, function, and stiffness in a previously reported clinical study of DSG 1%. (2)

METHODS: The OA knee study was a 12-week, prospective, randomized, double-blind, multi-center, parallel group study that compared DSG 1% with vehicle in subjects with OA of the knee. The MCII for OA as determined and recommended by Tubach F et al (3) was applied to this study. The MCII responder, a relative improvement of 20% or more from baseline was analyzed using the Cochran-Mantel-Haenszel test stratified by center. Depending on MCII response in relation to vehicle, responder based on improvement of 30% or more was also analyzed. Time to first MCII response was analyzed using the log-rank test.

RESULTS: Consistent with other efficacy results previously reported for this OA knee study, statistically significant differences were evident at week 1 and were maintained through week 12 for this post hoc MCII analysis. Subjects achieving a MCII response with DSG vs vehicle at Week 1 were: Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) pain, 66% vs 55%, *P*=0.011; WOMAC function 56% vs 42%, *P*=0.002; WOMAC stiffness, 62% vs 48%, *P*=0.002; POM, 66% vs 50%, *P*=0.0003. All DSG responses remained statistically significantly different from placebo through Week 12 with the exception of WOMAC pain. WOMAC pain based on 30% improvement at Week 1 (55% vs 42%, *P*=0.003) and Week 12 (66% vs 56%, *P*=0.019), suggests that a higher MCII response criteria may be relevant to consider for WOMAC pain in the context of this specific study. Time to first MCII response was lower with DSG vs vehicle (10 vs 29 days) for all 4 measures: WOMAC pain, *P*=0.0091; WOMAC function, *P*=0.0002; WOMAC stiffness, *P*=0.0076; POM, *P*=0.0002.

CONCLUSIONS: The MCII is a new way of understanding clinically important improvement by taking the perspective of the patient into account. Using the MCII to express results in percentages is more clinically relevant and understandable for both the patient and the primary care physician.(1) This post hoc analysis represents the first time that the MCII has been applied to DSG clinical trial results. The majority of patients treated with DSG achieved MCII responses within 1 week which were sustained for 12 weeks, providing additional evidence for the efficacy of DSG in the treatment of OA of the knee. 1. Kvien TK et al. *Ann Rheum Dis*. 2007;66 Suppl 3:iii40-1. 2. Barthel HR et al. *Semin Arthritis Rheum*. 2009;39(3):203-12. 3. Tubach F et al. *Arthritis Care Res (Hoboken)*. 2012;64(11):1699-707.

MINORITY AND LOW-INCOME URBAN INTERNAL MEDICINE PATIENTS ARE LESS LIKELY TO HAVE A SCALE AT HOME FOR SELF-WEIGHING.

Carolyn Bramante¹; Grace Lee²; Safira Amsili²; Jennifer A. Linde²; Sean Phelan²; Wendy Bennett²; Lawrence J. Appel³; Jeanne M. Clark³; Kimberly Gudzune³. ¹University of Minnesota, Minneapolis, MN; ²Johns Hopkins, Baltimore, MD; ³Johns Hopkins University, Baltimore, MD. (Control ID #3186035)

BACKGROUND: Daily self-weighing has been shown to be an effective component of evidence-based weight management interventions. Daily self-weighing requires regular access to a scale, however no prior research has examined what proportion of primary care patients have a scale in their home. Our objectives were to understand if patients have a scale in their home, the characteristics associated with lacking a home scale, and patient willingness to self-weigh.

METHODS: We enrolled 216 patients from three general internal medicine clinics in Baltimore, MD from Dec 2017-Feb 2018 to complete a one-time cross-sectional survey. The three clinics served three different patient populations: mixed-income urban/suburban; mixed-income urban; and low-income urban. Our primary dependent variable of interest was access to a scale in the home ("Is there a scale available to weigh yourself in your home?" (Yes/No)). Our independent variables included demographics, insurance status, clinic setting, and self-weighing. We examined the association between home scale access and these factors using t-tests and Chi² tests, as appropriate.

RESULTS: Our sample's mean age was 53 years, 71% were women, 71% identified as minorities (predominantly African American), and the mean body mass index (BMI) was 32 kg/m². Overall, 56% of patients had a scale in their home. There was no significant difference in home scale access by age, gender, insurance status, or BMI. Minority patients were less likely to have a home scale than white patients (46% vs 79%, p<0.01). Patients from the urban clinic serving low-income communities were less likely to have a home scale than patients from the other two clinics (35% vs 69% or 66%, p<0.01). Patients without a home scale were less likely to self-weigh at least weekly than patients who had a scale at home (13% vs 87%, p<0.01). Patients with heart failure were not more likely to have a scale at home (p=0.27). Among patients who did not own a scale, the most common reason reported for not owning a scale at home was "Scales cost too much," (32%); and 72% would weigh daily if they had a scale. Among all patients, 95% were willing to weigh weekly if a doctor recommended it, and 67% were willing to have their weights transmitted to clinic.

CONCLUSIONS: A substantial proportion (44%) of all primary care patients do not have a scale in their home, but the lack of a scale was most common among minority patients and patients from a low-income urban clinic. Cost was the most common barrier to owning a scale. Most patients were willing to self-weigh, and even to have their weights transmitted to clinic, but lacking a home scale was associated with a lower likelihood of self-weighing. Because self-weighing is an important weight-management behavior, future research addressing factors that improve home scale access for patients could enhance weight management services in the primary care setting.

MISSING PRIMARY CARE DESIGNATION IN SPECIALTY MENTAL HEALTH ELECTRONIC RECORDS CHALLENGES THE CARE COORDINATION OF PEOPLE WITH SERIOUS MENTAL ILLNESS

Maria E. Garcia¹; L. E. Goldman²; Marilyn Thomas¹; Stephen Chan⁴; Fumi Mitsuishi³; Dean Schillinger³; Christina Mangurian⁵. ¹University of California, San Francisco, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³UCSF, San Francisco, CA; ⁴University of California, Davis, Sacramento, CA; ⁵UCSF School of Medicine, San Rafael, CA. (Control ID #3186123)

BACKGROUND: People with severe mental illness (SMI) such as psychosis, bipolar disorder, and major depressive disorder die on average 10-25 years earlier than the general population. Many people with SMI are prescribed medications that increase cardiovascular risk, yet patients with SMI are less likely to access primary care and to be screened for cardiovascular risk factors. National efforts to improve preventive care and the overall health of people with SMI have promoted care coordination care between specialty mental health and primary care. In this study,

we assessed whether primary care clinics are accurately identified for patients in specialty mental health care settings in the public sector.

METHODS: Electronic record review was performed for patients within a large urban specialty mental health clinic who were enrolled in an intensive care management program. Analysis was limited to individuals within an integrated healthcare system that includes psychiatric, medical and laboratory services with separate electronic health records for mental health and medical clinics. 'Known primary care clinic' was defined as a matching clinic listed in the specialty mental health and medical electronic records. All others were designated as 'Unknown primary care clinic.' We assessed whether patient demographic factors predicted known primary care clinic using chi-square tests and whether having a known primary care clinic was associated with increased cardiovascular risk screening (for hypertension, obesity, diabetes, and/or hyperlipidemia through lab or biometric assessments).

RESULTS: Among 229 patients (66% male; mean age 49; 36% White, 30% Black, and 39% Asian; 69% with a diagnosis of schizophrenia; 87% taking antipsychotics), 28% did not have a known primary care clinic. Sex, age, race, psychiatric diagnosis, and psychotropic medication use were not associated with primary care clinic identification. Among these patients in an intensive care management program, there was no difference in screening for cardiovascular risk factors for patients with known vs. unknown primary care clinic. Overall, patients had higher rates of biometric assessments (blood pressure= 71%, obesity= 62%) than laboratory assessments (diabetes= 47%, hyperlipidemia= 40%).

CONCLUSIONS: The high rate of unknown primary care clinic assignment in a sample enrolled in intensive care management directly challenges efforts to improve care coordination between primary care and specialty mental health for people with severe mental illness. In this sample of patients, known primary care clinic was not associated with increased cardiovascular risk screening, despite high use of medications with known cardiovascular risk factors. To improve care coordination for people with SMI, and the overall health of this vulnerable population, systems changes to ensure accurate primary care information and communication between providers will be needed.

MISSING THE DEADLINE: HIGH RATES OF ABSENT AND UNTIMELY ACCESS TO SPECIALTY PALLIATIVE CARE IN PATIENTS WITH PERI-HOSPITAL MORTALITY AS A NOVEL QUALITY METRIC

Christopher Schifeling; Stacy M. Fischer. University of Colorado, Denver, CO. (Control ID #3181197)

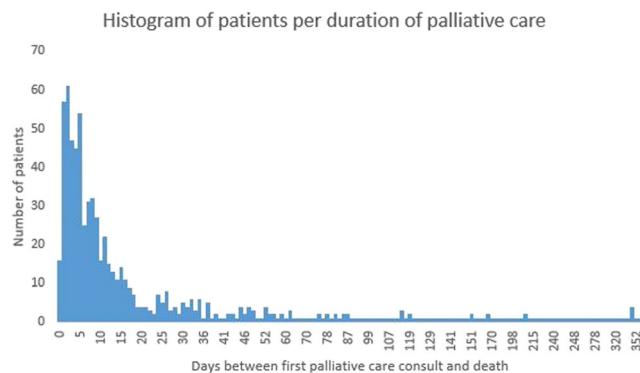

BACKGROUND: Despite mounting evidence that specialty palliative care improves patients' symptoms, caregiver burnout and alignment of health care usage with patient preference, these services are likely underutilized. There is, however, a paucity of data on missed opportunities for specialty palliative care. This study sought to determine the rate of missed and delayed opportunities for specialty palliative care in patients who died in the hospital or within seven days of discharge.

METHODS: A retrospective analysis of patients from a large academic medical center with a Joint Commission awarded palliative care team was conducted. Included were adults who died in the hospital or within seven days of discharge and had prior encounters with the medical center in the last 12 months of life. Excluded were patients who had a sudden or obstetrics-related death. Data from the Colorado Department of Public Health linked with the electronic medical record determined time from first palliative care consultation to death. Chi squared analysis and multivariate logistic regression were used to identify patient variables (derived from the medical record) that were associated with presence of specialty palliative care.

RESULTS: The sample included 2150 patients with 81% of patients dying in the hospital. Only 34% of patients had palliative care consultation which was higher for patients with cancer (43%) than those without

cancer (26%). Of patients with palliative care consultation the median time from first referral to death was eight days. Patients without palliative care referral had an average of 1.8 hospitalizations, 1.6 emergency room visits and 28 face-to-face clinic encounters in their last year of life. Specialty palliative care was positively associated with age less than 65 years old, white race, cancer, frailty, depression, chronic pain and having primary care visits in the last 12 months of life.

CONCLUSIONS: In spite of the general preference to avoid hospital deaths, patients who die in the hospital or shortly after discharge have a high degree of missed opportunities for specialty palliative care. This is a medical error that warrants greater attention. Using the rate of missed opportunities for specialty palliative care in this population as a quality metric will improve end-of-life care for patients', their caregivers and the entire healthcare system.

MITRAL LEAFLET CLIP PROCEDURE OUTCOMES: ANALYSIS FROM THE NATIONAL CARDIOVASCULAR DATA REGISTRY

Pedro Covas¹; Talal S. Alzahrani²; James McCaffrey²; Joseph Krepp²; Ramesh Mazhari²; Christian Nagy²; Jonathan Reiner². ¹George Washington University, Washington, DC; ²The George Washington University, Arlington, VA. (Control ID #3159437)

BACKGROUND: Mitral regurgitation is one of the most common valvular diseases worldwide. Treatment for severe mitral regurgitation (MR) commonly involves surgical replacement of the mitral valve, but for those who are poor surgical candidates, another option has become mitral valve repair with a mitral leaflet clip procedure (MLCP). In this study, we conducted a descriptive analysis for all patients who underwent MLCP in the United States to investigate preoperative, intraoperative, and postoperative characteristics, techniques, complications, and clinical outcomes.

METHODS: The National Cardiovascular Data Registry (NCDR) was used to summarize the baseline demographics and procedural quality measures of all patients who underwent MLCP between 2014 and 2017. The change in the demographics, mortality, complications, and clinical outcomes were summarized and visualized in graphs.

RESULTS: The number of subjects who underwent mitral valve repair increased from 1,023 subjects in 2014 to 5,075 in 2017. The overall mortality rates are relatively unchanged (2.6% to 2.4%). However, there was an improvement in 30-day mortality (4.5% to 4.0%). The rate of patients with low STS scores increased (34% to 50%). Overall, the rate of patients with functional MR who received mitral clips are low (<10%). Of note, there has been a decrease in the number of patients who are 80 years old and older (62% to 56%). Intra-operatively, there were fewer complications (14.6% to 12.2%) including fewer clips not deployed (5.3% to 3.5%) related to a decrease in leaflets not being able to be grasped. Interestingly, there was an increase in the percentage of patients with mitral valve pressure gradient <= 5 mmHg (71.5% to 72.5%). Regarding 30-day follow-ups, our results have shown that residual mitral valve

regurgitation (moderate or greater) has decreased from 39% to 5%, with a decrease in the number of clips attempted per patient. NYHA class IV symptoms at 30 days decreased from 4.2% to 3.1%. Finally, follow up echocardiograms changed in approach, with an increase in trans-thoracic (TTE) and a decrease in trans-esophageal (TEE) (86% TEE in 2014 vs. 86% TTE in 2017).

CONCLUSIONS: Our interpretation shows a trend that MLCP continues to be a viable option for MR. The rate of procedures is expected to increase especially among younger patients with low STS scores and functional MR as results of the COAPT trial. We expect a continued decrease in complications and continued intra-operative success shown by improvement in mitral regurgitation.

MORAL DISTRESS IN INTERNAL MEDICINE RESIDENTS

Stephanie E. McLaughlin; Harriet Fisher; Colleen Farrell; Kathleen Hanley. New York University School of Medicine, New York, NY. (Control ID #3184637)

BACKGROUND: Moral distress occurs when the ethically correct action cannot be taken because of internal or external constraints. High levels of moral distress are associated with burnout in medical providers. A better understanding of factors associated with high moral distress during post-graduate training is crucial to executing interventions to lower rates of burnout during residency.

METHODS: This is a mixed methods prospective observational cohort study that aims to enroll 90 internal medicine (IM) residents on a rolling basis from one IM residency program (12/2018-12/2019). Data is being collected by a series of 3 surveys over 1 year, using the previously validated Moral Distress Scale, to evaluate frequency and intensity of distress associated with specific situations experienced or witnessed by residents during training. This initial analysis, bivariate and multivariate regression of quantitative data from the first time point (survey #1), investigated associations between moral distress scores and demographic, training-specific, and intrinsic personal factors of participants. Analysis of qualitative open-ended questions further explored causes of moral distress and as well as coping mechanisms employed by residents.

RESULTS: 32 IM residents (44% PGY-1, 28% PGY-2 and 28% PGY-3) have been enrolled thus far. 53% of resident participants identify as male, 43% as female (and 3% as other). 66% were "Categorical" residents, 25% "Primary Care (PC)," and 9.4% "Preliminary Year" PGY-1 Interns. Mean and median moral distress scores were: 66.8 (SD 31.0) and 61 (range 16-132). In multivariate linear regression "PC" residents had scores 31 pt. higher compared to "Categorical" residents ($p=0.009$). Male residents had scores 25pt lower than female residents ($p=0.008$), and PGY year conferred an incremental score increase of 11 pt. per year ($p=0.057$). The model was adjusted for covariates: PGY-year, gender, age, and/or program type. Themes regarding causes of moral distress included: lack of resources, situations when patient care is dictated by cost-saving measures, and aggressive futile care. Coping mechanisms included: debriefing with team members or others outside of work, active individual reflection, exercise/yoga/meditation, participating in activities and social events outside of medicine, reflective writing/journaling, and suppression and/or distraction.

CONCLUSIONS: In this preliminary analysis, residents in the PC track have higher average moral distress scores. It is unclear whether residents prone to more moral distress self select into this track or whether distress is related to differences in training between PC and categorical tracks. Additionally, more senior residents had average higher scores. This supports the theory of residual moral distress; an increasing amount of moral distress is experienced as a provider witnesses/experiences distressing events over time. Most coping strategies involve social connection and reflection.

MORTALITY AMONG NORTHERN NEW ENGLAND ADULTS BY TOWNSHIP TYPE

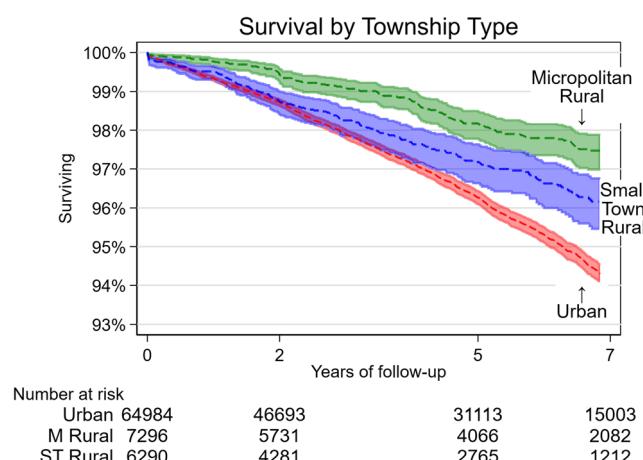

Timothy B. Plante¹; Insu Koh¹; Dennis A. Plante¹; David W. Ferguson³; Neil A. Zakai¹; Kathleen Fairfield². ¹Larner College of Medicine at the University of Vermont, Burlington, VT; ²Maine Medical Center, Portland, ME; ³Waldo County General Hospital, Belfast, ME. (Control ID #3186074)

BACKGROUND: Adults in rural areas die younger than adults in urban areas. Northern New England states are the most rural in America and comprise a greater proportion of adults in micropolitan areas, which are large towns within rural areas. Whether survival differs among these micropolitan areas is unknown. We sought to assess all-cause mortality by township type among Northern New England adults receiving their primary care at academic clinics.

METHODS: We downloaded structured electronic health record data from 86,733 adults receiving primary care at University of Vermont Medical Center-affiliated practices between October 1, 2010 and June 30, 2018 who were aged 18 at any point throughout the follow-up, censoring data prior to age 18. We applied Rural-Urban Commuting Areas (RUCA) codes to first documented ZIP codes to determine township type, defining RUCA codes 1-3 as urban, 4-6 as micropolitan rural, and 7-10 as small town rural. We calculated sex, age, and race-adjusted hazard ratios (HRs) for survival by township type. We visualized survival using Kaplan-Meier curves.

RESULTS: Among participants in the present analysis, mean (SD) age was 46 (19) years on 10/1/2010, 56% were female, and 92% were white; 83% were urban, 9% were micropolitan rural, and 8% were small town rural. Over a median (IQR) follow-up of 4.6 (1.3-7.6) years, there were 2,651 deaths over 341,136 person-years (0.8 deaths/100 person-years). The mortality incidence rate was lowest among micropolitan rural (0.4/100 P-Y; 95% CI 0.3, 0.4), then small town rural (0.6/100 P-Y; 0.5, 0.7), and urban (0.8/100 P-Y; 0.8, 0.9). When compared to micropolitan rural, the adjusted HR for mortality was 2.2 (95% CI 1.9, 2.7; P<0.001) for urban and 1.8 (1.4, 2.3; P<0.001) for small town rural. Survival curves are shown in Figure 1.

CONCLUSIONS: Adults living in urban and small town rural areas experience a disproportionate burden of mortality when compared to adults in micropolitan rural areas. Efforts to identify and modify the most important risk factors for mortality in these populations are important interventions to improve population health.

MORTALITY AT PRIVATE FOR-PROFIT AND PRIVATE NOT-FOR-PROFIT HEMODIALYSIS CENTERS: A SYSTEMATIC REVIEW AND META-ANALYSIS

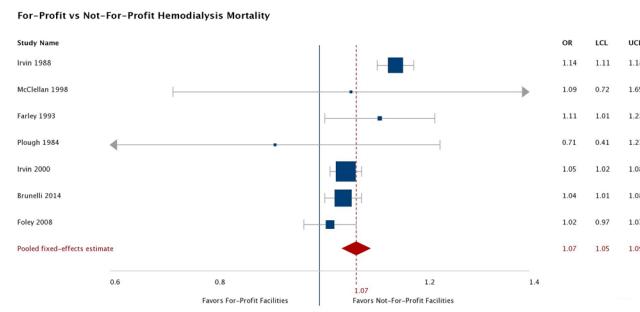

Samuel L. Dickman¹; Reza Mirza²; Maryam Kandi²; Michael Incze³; Rakhshan Kamran²; Raad Yameen²; Ying Zhang²; Arnav Agarwal²; Lorin Dobiba²; Rachel Couban²; Steven Hanna²; Gordon Guyatt⁴. ¹University of California, San Francisco, Oakland, CA; ²McMaster University, Hamilton, ON, Canada; ³University of California, San Francisco, San Francisco, CA; ⁴McMaster University, Dundas, ON, Canada. (Control ID #3186034)

BACKGROUND: Most of the 630,000 Americans on hemodialysis for end-stage renal disease receive care at private for-profit (FP) or private not-for-profit (NFP) facilities. FP facilities comprise 79% of all dialysis providers and may lead to worse outcomes than NFP facilities.

METHODS: We searched ten databases (MEDLINE, HealthStar, EMBASE, PubMed, Cochrane Library, Web of Science, Proquest Dissertations and theses, ProQuest Business Premium Collection, Econlit, and CINAHL) for studies published between January 2001 to March 2018 comparing risk-adjusted mortality rates at FP vs. NFP hemodialysis facilities. We used similar criteria to a large 2002 meta-analysis on private dialysis outcomes: we included studies in any language, published and unpublished, with non-overlapping data. Pairs of reviewers screened 8,876 titles and abstracts, of which 137 full-text articles were reviewed. Study characteristics, results, and risk of bias were assessed by two independent reviewers and discrepancies were resolved by consensus. We harmonized outcomes and conducted pooled fixed- and random-effects meta-analysis.

RESULTS: Seven observational studies, all from the US, were included in the final analysis. No randomized trials met inclusion criteria, and risk of bias was moderate to high. Point estimates in six studies showed worse risk-adjusted mortality rates at FP relative to NFP facilities; the single study with conflicting results compared free-standing FP dialysis centers with hospital-based NFP centers and thus may have been subject to residual confounding by severity of illness. Pooled fixed effects meta-analysis found an OR of mortality in FP relative to NFP facilities of 1.07 (95% CI 1.05 - 1.09). Random-effects estimates were substantially similar. We found no evidence from more recent studies that mortality differences between FP and NFP dialysis centers have narrowed.

CONCLUSIONS: Patients at for-profit facilities face 6% greater odds of death annually than patients at not-for-profit facilities with similar risk profiles, a consistent pattern since the most recent comparable meta-analysis was published in 2002. As many as 5,000 deaths would be averted annually if mortality rates at FP facilities matched those at NFP facilities. Despite long-standing concerns about patient safety at FP facilities, public policies have failed to improve outcomes at FP dialysis centers or to limit their rising market share.

MOTIVATIONS FOR AND USE OF COMPLEMENTARY AND ALTERNATIVE MEDICAL MODALITIES FOR ACUTE PAINFUL CONDITIONS

Erica Morse¹; Colleen Ross¹; Stanley Xu¹; Scott Clemensen²; Shaweta Babar³; Heidi Clune²; Leonard Wisneski⁴; Melissa de Picciotto²; Ingrid A. Binswanger¹. ¹Kaiser Permanente, Aurora, CO; ²Kaiser Permanente, Boulder, CO; ³Kaiser Permanente, Denver, CO; ⁴University of Colorado, Aurora, CO. (Control ID #3168415)

BACKGROUND: Opioids are commonly prescribed to manage acute pain. However, alternative approaches are needed. There is evidence suggesting that non-pharmacologic and complementary and alternative medical (CAM) modalities may be effective in helping patients manage painful conditions. In contrast to CAM use for chronic pain, there has been less research on the use of CAM for acute pain episodes, such as those presenting in urgent care settings. Our objective was to describe motivations for, beliefs about, and use of CAM among patients who accessed urgent care for a painful condition. We also sought to examine factors associated with CAM use after an urgent care visit.

METHODS: We developed an electronic survey measuring motivations for and beliefs about CAM use from the Attitudes and Beliefs About CAM instrument and questions about utilization of CAM one year before and 60 days after an urgent care visit. Adult members enrolled in the Kaiser Permanente Colorado Health Plan were recruited via email eight weeks after an urgent care visit for a painful condition between June and August 2018 and asked to complete the survey. We used descriptive statistics and unadjusted and multivariable logistic regression models to examine the association between prior CAM use, attitudes and beliefs about CAM, over-the-counter (OTC) medication use, self-reported prescription opioid use, and prescription non-opioid pain medication use, with CAM use after an urgent care visit.

RESULTS: There were 200 respondents to the survey (9% of total recruited). They were mostly white (86%) and female (72%) presenting at urgent care with an acute (82%) and painful (88%) condition. Most participants believe CAM decreases emotional distress (67%), helps reduce pain (72%), and helps cope with the experience of having pain (64%). Most were interested in using CAM modalities in urgent care if offered (73%). Among those who used CAM after urgent care, most reported they used it to help reduce pain (81%). A larger percentage of individuals with a history of CAM, used CAM following their urgent care visit compared to those without a history of CAM use (84% vs 17%). The unadjusted models indicated individuals were more likely to use CAM services after an urgent care visit if they presented with an acute condition (OR 2.5, 95% CI 1.1, 5.4). Pre-urgent care use of OTC medications (OR 1.1, 95% CI 0.4, 3.5), and prescription opioid (OR 0.7, 95% CI 0.4, 1.4) and non-opioid pain relievers (OR 0.9, 95% CI 0.5, 1.9) were not significantly associated with post CAM use. Multivariable models demonstrate that prior CAM use was the only factor significantly associated with post urgent care CAM use (OR 25.5, 95% CI 12.0, 53.9).

CONCLUSIONS: Our findings suggest that patients are interested in CAM services in urgent care settings to help manage acute pain. Patients are more likely to use CAM after an urgent care visit if they had a prior history of CAM use. Further research on the effectiveness of various CAM modalities for acute pain is needed.

NATIONAL SURVEY OF INTERNAL MEDICINE RESIDENTS: PERCEPTION OF SUPERVISION AT NIGHT

Jillian S. Catalanotti²; Alec O'Connor³; Kathryn Fletcher¹. ¹Medical College of Wisconsin/Milwaukee VAMC, Milwaukee, WI; ²The George Washington University, Washington, DC; ³William L. Morgan Professor of Medicine University of Rochester School of Medicine and Dentistry, Rochester, NY. (Control ID #3184235)

BACKGROUND: Balancing autonomy and supervision is one of the most difficult goals for residency training programs to achieve. Night time rotations historically have been opportunities for residents to experience greater autonomy, but increasing patient acuity and volume in many hospitals, coupled with greater awareness of the importance of resident supervision to ensure patient safety, have led to a rise in the number of teaching hospitals that employ in-house overnight hospitalists ("nocturnists"). We sought to understand residents' perspectives on the adequacy of overnight supervision and barriers to contacting their overnight supervising attendings.

METHODS: The Internal Medicine In-Training Examination (ITE) is a national voluntary examination administered annually in August and September. Each year, a select group of survey questions is administered at the end of the exam. In 2017, the ITE contained 7 questions about overnight supervision. We provide descriptive statistics of closed-ended questions. We performed content analysis of the open-ended questions and sorted the responses into categories based on the Systems Engineering Initiative for Patient Safety (SEIPS) model which identifies contributors to patient safety problems related to 5 factors: Tasks, tools/technology, people, organization, and environment.

RESULTS: There were 20,744 respondents, with 34% PGY1s, 35% PGY2s and 31% PGY3s. Fifty-seven percent were male, 93% were categorical internal medicine or primary care residents, and 62% were US medical graduates. Over half (53%) reported having a supervising attending in the hospital overnight. Most residents (83%) reported that their supervision at night was adequate to ensure patient safety "always" or "most of the time;" 11% reported "sometimes" and 6% said "rarely" or "never." The 3 most common barriers to contacting attendings at night were: 1) wanting to make their own decisions, 2) not wanting to wake up an attending, and 3) the attending not being in the hospital. We asked what other barriers exist and categorized free text responses into each of the SEIPS categories. Programmatic culture discouraging residents from asking attendings for help (Organizational) was common. Other barriers included having access to other resources (e.g., fellows) (Organizational), being too busy to call (Task), believing they would not receive helpful input (Person), and previous attending behavior ("toxic, condescending, rude") discouraging calling (Person).

CONCLUSIONS: About half of medicine residents in 2017 reported access to in-hospital attending supervision overnight. Substantially more than half of residents feel adequately supervised at night. Many barriers to contacting attendings were identified. Program leaders should explore their program's culture to understand their residents' perceived barriers to seeking attending level supervision. Attending behavior and a culture that suggests it is "weak" to involve attendings when residents feel that they need them should be addressed.

NATURAL LANGUAGE PROCESSING TO IDENTIFY PATIENTS WITH COGNITIVE IMPAIRMENT FROM THE ELECTRONIC HEALTH RECORDS

Khalil Hussein¹; Tielman Van Vleck¹; Lili Chan¹; Girish Nadkarni¹; Parul Agarwal¹; Monica Mindt^{2, 1}; Alex Federman¹; Juan P. Wisnivesky¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Fordham University, New York, NY. (Control ID #3186148)

BACKGROUND: As the U.S. population ages, the prevalence of cognitive impairment among adults will rise, and early detection of persons with cognitive impairment will become a public health imperative to allow for early interventions to reduce the risk of progression to dementia and to facilitate the enrollment of persons with dementia into care programs. While ICD9/10 codes are highly specific for cognitive impairment, they have low sensitivity. Therefore, alternative tools to identify people at highest risk of developing cognitive deficits are needed. Natural language processing (NLP) is an automated process that can be applied to electronic health records (EHR) to search for patterns of words. Our aim was to determine the sensitivity and specificity of a NLP algorithm for identifying cognitive impairment in adults.

METHODS: We utilized a NLP algorithm, CLiX NLP, to identify subjects with cognitive impairment using clinical notes from the Epic EHR and validated the algorithm using cognitive performance data from two cohort studies of older adults with asthma or COPD who were simultaneously enrolled into the BioMe Biobank at the Mount Sinai Hospital (n=199). All subjects were prospectively administered the mini-mental status exam (MMSE); subjects with a score of <24 were considered cognitively impaired. Terms for cognitive impairment were selected from SNOMED Clinical Terms by two physician consensus. The NLP algorithm was used to parse all available notes from the EHR of subjects with the following restrictions: (1) For subjects with normal MMSE scores, only notes within 6 months before or after MMSE administration, and (2) For subjects with MMSE scores <24, all notes from 6 months prior to MMSE administration until December 2017. 12 additional subjects were excluded for having no encounters documented in the EHR during this time window. Additionally, performance of NLP was compared with manual chart review of 50 charts. Test statistics sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were generated.

RESULTS: The mean age of subjects was 68 years old with standard deviation (SD) of 6.8. 25% were male, 29% Caucasian and 33% African-American. 54% reported Hispanic ethnicity. Mean MMSE score was 24.8 (SD 3.8); 40% had MMSE<24. Mean MMSE scores were significantly lower in subjects identified as having cognitive impairment by NLP compared to those that were not, 21.9 (SD 3.9) vs. 24.7 (SD 3.7), respectively ($p<.0001$). Sensitivity of NLP for cognitive impairment using MMSE as a gold standard was 44.2%, specificity 87.3%; PPV 69.1%, and NPV 70.8%. Sensitivity of NLP for cognitive impairment using manual review as a gold standard was 84.6%, specificity 62.2%, PPV 44.0%, NPV 92.0%.

CONCLUSIONS: NLP can be used to identify older adults with cognitive impairment with moderate specificity. Refinement of these NLP methods may result in an effective approach to identify subjects with cognitive impairment from unstructured clinical electronic data sources.

NEIGHBORHOOD VIOLENCE AS A DETERMINANT OF ACCESS TO RESOURCES AND HEALTH STATUS ON THE SOUTH SIDE OF CHICAGO

Maya Isaacsohn¹; Monica E. Peek²; Nichole Smith²; Lydia A. Fu²; Elizabeth L. Tung². ¹Emory University, Atlanta, GA; ²University of Chicago, Chicago, IL. (Control ID #3185482)

BACKGROUND: Neighborhood violence has been linked to negative health consequences, such as obesity and hypertension. Although numerous studies have investigated the relationship between neighborhood violence and access to outdoor physical activity resources, such as parks, fewer studies have examined the relationship to other health resources, such as fresh fruits and vegetables. The purpose of this study was to examine the relationship between neighborhood violence and use of community resources, including outdoor physical activity spaces, indoor gyms, grocery stores and pharmacies.

METHODS: Adult primary care patients (N=506) from two clinics in Chicago were recruited to complete a one-time survey. Surveys queried participants about use of community resources (i.e., "Do you usually use a [resource] within walking distance of your home?"). Survey responses were paired with objective, geocoded data from the Chicago Police Department. The number of fatal and non-fatal shootings were aggregated to the community area-level, as a proxy for violent crime exposure, and classified into 4 crime exposure risk quartiles. Participant addresses and body mass indexes (BMI) were retrieved from the electronic health record; obesity was defined as BMI 30mg/k2. Logistic regression models were used to independently assess (1) use of community resources and (2) obesity status as a function of violent crime exposure. Final models adjusted for age, gender, race/ethnicity, education, and insurance status.

RESULTS: The cooperation rate was 61%. Participants were predominantly female (72%) and non-Hispanic black (76%). Median number of shootings

per community area was 58 (interquartile range, 21-128). Living in the highest quartile of violent crime was inversely associated with use of a grocery store (AOR=0.31; 95% CI, 0.13-0.72) or pharmacy (AOR=0.20; 95% CI, 0.09-0.47) within walking distance from home. Associations with location of exercise were not significant. Use of a grocery store within walking distance from home was also inversely associated with obesity status (AOR=0.43; 95% CI, 0.26-0.70); associations with use of pharmacy and exercise resources were not statistically significant. Similarly, living in the highest quartile of violent crime was associated with obesity status (AOR=2.76; 95% CI, 1.10-6.94).

CONCLUSIONS: Exposure to a higher number of neighborhood shootings was associated with poorer access to neighborhood resources, including grocery stores and pharmacies. Poorer access to grocery stores was also associated with obesity status. Contrary to expectations, access to exercise resources was not associated with violent crime or obesity status. Strategies to improve chronic disease management should consider neighborhood violence as a barrier to access - beyond access to exercise resources, but also access to food and medication resources.

NET IMPACT OF SOCIAL DETERMINANTS OF HEALTH ON CARDIOVASCULAR RISK FACTORS AND BEHAVIORS

Ana M. Palacio¹; Heidy Medina¹; Maritza Suarez²; Leonardo Tamariz¹

¹University of Miami, Miami, FL; ²University of Miami, Miami, FL. (Control ID #3185322)

BACKGROUND: Cardiovascular diseases disproportionately affect disadvantaged populations leading to calls to address social determinants of health (SDH) as a preventive strategy. However, the limited information on the net impact that each SDH factor plays in CVD risk prevents the dissemination of SDH collection strategies across health systems. Thus the goal of our study is to create a weighed SDH score for cardiovascular risk using patient reported and geocoded SDH and to test the impact of each SDH factor on the Framingham risk score and on individual traditional cardiovascular risk factors.

METHODS: We conducted a retrospective cohort study of primary care patients at the University of Miami Health System who answered a SDH survey between September 16, 2016 and September 10, 2017. The survey included SDH domains recommended by the AHA position statement and by the National Academy of Sciences, Engineering and Medicine. We selected the Framingham risk score (FRS) as well as all traditional cardiovascular risk factors as our outcome metrics. We calculated the SDH score for Cardiovascular risk by conducting linear regression of the FRS outcome using all the SDH variables. We used the beta coefficients of the regression to create the SDH score. We correlated the SDH Score in tertiles to the FRS risk categories and to the achievement of clinical targets for the traditional cardiovascular risk factors. We also evaluated the correlation of SDH to health behaviors such as smoking and physical activity.

RESULTS: We included 2,876 patients with a mean age of 53.8 ± 15.8 , 61% were female, 9% were Black, 38% were Hispanic and 87% reported speaking English. The mean household income was \$36,777 (42,813-67,760). The statistically significant beta coefficients in the FRS model corresponded to being born outside of the US but non-Hispanic, living alone, have a high social isolation score and a low geocoded-based median household income ($p<0.01$). The calculated SDH score ranged from 0 to 59. Increasing tertiles of SDH score were significantly associated with high FRS, with poor blood pressure and diabetes control and with sedentary lifestyle. In adjusted models, financial strain, health literacy, stress, education and median household income were significant correlates of weekly exercise while being Black, Hispanic, born outside the US and having low median household income were associated to obesity (table).

CONCLUSIONS: increasing values of a weighted SDH score are associated with increasing CVD risk suggesting that this approach could be a useful tool for risk stratification. The net impact of SDH varied by CVD risk factor evaluated, however, all SDH impacted at least one outcome and therefore should be included in SDH collection tools.

NEW MODELS FOR EARLY WARNING OF DECOMPENSATION AND DEATH IN AN ACUTE CARE GENERAL MEDICAL SETTING.

Russ Clay^{1, 2}; John Voss¹; John E. Ainsworth²; Joel M. Schechtman¹; Andrew Barros¹; Valentina Baljak²; Megan Pierce¹. ¹University of Virginia, Charlottesville, VA; ²UVA Health System, Charlottesville, VA. (Control ID #3180902)

BACKGROUND: Published vitals-based early warning tools may suffer from low positive predictive value (PPV) and low sensitivity (SENS) when applied clinically, and traditional methods of model evaluation do not fully represent clinical implementation trade-offs. We sought to 1) develop new early warning methods & models for the acute care; 2) develop an improved method of evaluating the clinical model trade-offs.

METHODS: Data from 8,706 unique hospital General Medicine service stays from 7/2017 - 11/2018 were extracted from the EHR including vital signs, CBC and metabolic panels, and nursing assessments. Using these measures, we created excess risk (ER) and random forest (RF) models to predict mortality 12-24 hours before death. For ER, we used Rothman's approach (2013) to estimate the non-linear excess risk of a death associated with input values and derive a total patient level excess risk of mortality. For the RF model, all input measures were used for training. For both models, the data was split into training (70%) and test (30%) partitions. We evaluated models by simulating their implementation on time-series structured historical data, incorporating a 6-hour lockout on model fires to mimic operational alerts, calculating the PPV, SENS and daily model fire rate. The bootstrap method was used to calculate confidence intervals. ER and RF model performance (including vitals, labs, and nursing data) was compared to the published NEWS model (vitals only) using traditional methods (AUC) as well as PPV/SENS/Fire Rate (table).

RESULTS: Analysis demonstrated an AUC of 0.87 [0.865, 0.874] for the ER, 0.847 [0.843, 0.851] for the RF and 0.806 [0.805, 0.808] for the NEWS model, showing superiority of both the ER and RF models to NEWS. For comparable fire rates of ~4/day (for a census of 80 patients), model ranking for SENS+PPV was ER>RF>NEWS.

CONCLUSIONS: This evaluation method of PPV/Sensitivity/Fire Rate indicates that the ER model outperformed the RF and NEWS models and that adding lab values and nursing assessments boosts the performance of the ER and RF models versus the vitals-based NEWS model. In evaluating model performance, sites will differ in terms of what are perceived to be optimal performance characteristics (PPV/Sensitivity/Fire Rate) given the trade-offs involved.

NON-CONSENSUAL OPIOID TAPERING AMONG VETERANS RECEIVING LONG-TERM OPIOID THERAPY

Joseph W. Frank^{1, 2}; Evan Carey²; Anne Hale³; Charlotte Nolan⁴; Erin E. Krebs⁵. ¹University of Colorado School of Medicine, Aurora, CO; ²Rocky Mountain Regional VA Medical Center, Aurora, CO; ³Veterans Affairs, Denver, CO; ⁴Veterans Health Administration, Denver, CO; ⁵Minneapolis VA Health Care System, Minneapolis, MN. (Control ID #3185405)

BACKGROUND: There is inadequate evidence of benefit from long-term opioid therapy (LTOT) and growing evidence of opioid-related harms. Expert guidelines recommend assessment of benefits and risks of LTOT, and when risks exceed benefits, these guidelines recommend reduction or discontinuation of LTOT using individualized treatment plans. However, patients' goals may not align with recommendations to reduce or discontinue LTOT. We examined Veterans' experiences with non-consensual opioid dose reduction or discontinuation ("opioid tapering").

METHODS: We conducted a cross-sectional study within a national prospective cohort study, the Effects of Prescription Opioid Changes for Veterans (EPOCH) Study. The EPOCH Study identified Veterans on LTOT, defined as 150 days' supply in 180 days with no gaps >40 days, and 9,253 Veterans completed a baseline survey in 2015 (92% by mail, 8% by phone). We randomly selected 600 Veterans who met two criteria at EPOCH baseline:

1. completed mail survey; and 2. prescribed 50mg morphine equivalent daily dose (MED). We invited these individuals to participate in a structured phone interview at the 18-month EPOCH timepoint and completed 316 interviews (53% response rate). Interviews examined Veterans' experiences with opioid tapering as well as domains including pain severity, function, mood, sleep, fatigue and social isolation. We obtained data on demographics, medications and diagnoses from the electronic health record. We used the chi-square test to examine bivariate associations with demographic characteristics, comorbid diagnoses and medication characteristics. All analyses were conducted using R (Vienna, Austria).

RESULTS: The study sample was 73% age 60 years or older, 92% male and 87% White. The most common pain diagnoses were back pain (76%) and other joint pain (46%). Opioid medication doses at EPOCH baseline were 50-99mg MED (53%), 100-199mg MED (37%) and 200+mg MED (10%). Overall, 68% reported fair or poor health status, and 51% reported pain severity that was slightly worse or much worse than 1 year ago. A majority (190/316, 60%) reported tapering in the past year or discontinuing opioid medications. Past year opioid tapering was associated with White race ($P=.02$) and marital status ($P=.01$). Among participants who reported past year opioid tapering ($N=150$), 50% reported that opioid medications were tapered "without your consent or against your wishes". In bivariate analyses, no patient characteristics were significantly associated with self-reported non-consensual opioid tapering.

CONCLUSIONS: Among Veterans prescribed high-dose long-term opioid therapy, a majority report recent dose reduction or discontinuation, and non-consensual opioid tapering is common. Future studies should explore provider- and facility-level correlates of non-consensual opioid tapering and examine the effects of non-consensual tapering on the potential benefits and risks of opioid tapering.

NON-OPIOID PRESCRIPTION ALTERNATIVE INITIATIVE (NOPAIN) - AN EDUCATIONAL INTERVENTION TO IMPROVE UTILIZATION OF NON-OPIATE ANALGESICS IN THE TREATMENT OF BACK PAIN.

Scott Holmes¹; Edward Ewen². ¹Christiana Care Health System, Philadelphia, PA; ²Christiana Care Health System, Newark, DE. (Control ID #3177463)

BACKGROUND: The use of chronic opioid therapy (COT) has grown exponentially over the last 10 years, but there is currently no evidence for its use in the treatment of chronic back pain. The Non-Opioid Prescription Alternative Initiative (NOPAIN) focused on the effectiveness of an educational intervention to improve utilization of non-opiate pain medication. The study aimed to improve provider knowledge deficits of non-opioid adjuncts with an educational intervention based on the ACP's Clinical Practice Guideline for noninvasive treatment of low back pain.

METHODS: NOPAIN is a prospective cohort study of patients seen in an urban Internal Medicine primary care clinic between April 2017 and December 2017. Individuals were identified by ICD-10 diagnosis of low back pain, with all demographics, diagnoses, and prescribing history obtained through the institution's electronic health record. A non-opioid prescription alternative protocol was created using the ACP's Clinical Practice Guideline for noninvasive treatment of low back pain. Education sessions took place during resident conferences and providers were then given ID badge cards summarizing the recommendations. The control group were the patients of attending physicians, whom did not receive the educational intervention. Data was then examined to determine whether prescribing patterns changed based on the NOPAIN intervention, evaluating the frequency of opioid versus non-opioid analgesic prescriptions. Comparisons between groups were evaluated using the related samples signed Wilcoxon rank test and Chi-square (SPSS 25.0).

RESULTS: Of the 8044 patients seen in 2017, 1053 (13.1%) received opioid prescriptions, 133 (1.7%) were identified as COT patients, and 96 (1.2%) of these were diagnosed with back pain. Of this group, 40 patients were under the care of resident physicians, while 56 were treated

by attending physicians. In the study period, the use of pain adjunct prescriptions (SNRI, Skeletal Muscle Relaxants, TCA, and Anticonvulsants) increased by 30% ($p < 0.05$), along with a 22.5% ($p < 0.05$) increase in NSAID prescriptions. Additionally, the mean morphine equivalent dose (MED) per day decreased by 19.8% in the resident intervention group (64.9mg to 52.1mg, $p = 0.85$). There were fewer changes in the prescription rates of pain adjunct medications among the 56 patients in the attending physician control group, with an increase by 12.5% ($p = 0.23$). However, there was an increase in the mean MED per day by 8.2% (74.4mg to 81.1mg, $p = 0.71$).

CONCLUSIONS: This NOPAIN study suggests that when provided with medication guidelines and dosing recommendations, the prescribing of non-opioid alternatives increases in COT patients with back pain. Further study is needed to determine if the use of non-opioid analgesics results in lower MED in these patients. Provider education is a key component of clinical practice, and this data exemplifies the importance of continued provider education on non-opioid analgesic medications for low back pain.

NON-PHARMACOLOGICAL THERAPY USE FOR CHRONIC PAIN AMONG US MILITARY VETERANS ON LONG-TERM OPIOID THERAPY

Elizabeth S. Goldsmith^{1, 2}; Richard F. MacLennan²; Agnes C. Jensen¹; Barbara Clothier¹; Siamak Noorbalaoochi^{1, 2}; Brian C. Martinson^{1, 3}; Melvin T. Donaldson²; Erin E. Krebs^{1, 2}. ¹Minneapolis Veterans Affairs Health Care System, Minneapolis, MN; ²University of Minnesota, Minneapolis, MN; ³HealthPartners Institute, St. Paul, MN. (Control ID #3180406)

BACKGROUND: Chronic pain is a major cause of disability in the US, and opioid prescriptions rose amid limited availability and awareness of other pain therapies. Though many non-pharmacological therapies (NPT) are effective for chronic pain, little is known about NPT use patterns among people prescribed opioid analgesics. We examined NPT use within a national sample of US military veterans on long-term opioid therapy for chronic pain.

METHODS: The Effects of Prescription Opioid Changes in Veterans (EPOCH) study established a national cohort of 271,892 Veterans Affairs patients prescribed long-term opioid therapy for chronic pain. A representative sample received a survey including questions about past-year use of non-pharmacological therapies to treat or cope with chronic pain. We use descriptive statistics, generalized linear regression and latent class analysis to describe patients' self-reported NPT use patterns and to examine associations of NPT use with demographic and clinical characteristics and with patient-centered pain measures.

RESULTS: 8,891(65%) of 13,660 invitees completed the NPT questionnaire. Female sex and younger age were associated with use of every non-pharmacological therapy for chronic pain. Higher pain-related functional interference, higher prescribed opioid dose, and psychiatric diagnoses (depression, anxiety, PTSD) were associated with psychological skills-related NPT (meditation, relaxation, psychotherapy). Lower pain-related functional interference and lower physical comorbidity were associated with movement skills-related NPT (aerobic exercise, stretching/strengthening). Lower physical comorbidity was associated with manual therapy (acupuncture, chiropractic adjustment or manipulation, massage).

CONCLUSIONS: Findings can inform implementation and clinical research on non-pharmacological therapies for chronic pain, and raise questions about health system-related factors. Further analyses will examine how participants' NPT use relates to pain-related functional interference, opioid dosing, and quality of life outcomes over time.

Table. Characteristics of U.S. military veterans on long-term opioid analgesics reporting past-year use of non-pharmacological therapies for pain.

| Therapy type | Users N (%) | Female N (%) | Age Mean (SD) | Number of pain sites ¹ Mean (SD) | Functional interference ² Mean (SD) | Opioid dose ³ Mean (SD) | Long-acting opioid use N (%) | Physical comorbidity ⁴ Mean (SD) | Depressive disorder N (%) | Anxiety disorder N (%) | PTSD N (%) |
|----------------------------|------------------|-----------------|------------------|---|--|--|------------------------------------|---|---------------------------------|------------------------------|------------------|
| All respondents | 8,891 (7.86%) | 699 (7.86%) | 64.0 (10.6) | 6.80 (1.2) | 6.51 (2.12) | 51.2 (62.6) (28.4%) | 2,526 (32.0%) | 1.47 (1.71) (30.1%) | 2,673 (15.3%) | 1,358 (22.6%) | 2,007 |
| Psychological skills-based | 4,180 (47.0%) | 467 (11.1%) | 61.4 (10.7) | 7.14 (2.05) | 6.86 (1.97) | 54.6 (66.6) (33.8%) | 1,341 (31.7%) | 1.37 (1.65) (31.0%) | 1,784 (16.2%) | 915 (22.5%) | 1,395 (35.1%) |
| Meditation / mindfulness | 1,020 (11.7%) | 114 (11.5%) | 59.8 (11.2) | 7.15 (2.07) | 6.83 (1.98) | 56.0 (64.2) (28.4%) | 591 (30.5%) | 1.27 (1.66) (31.2%) | 764 (16.2%) | 394 (22.5%) | 1,200 (35.1%) |
| Relaxation techniques | 3,122 (35.1%) | 378 (12.1%) | 61.1 (11.0) | 7.10 (2.05) | 6.71 (1.98) | 54.4 (65.0) (31.7%) | 989 (33.0%) | 1.37 (1.68) (30.1%) | 1,188 (16.2%) | 641 (20.5%) | 924 (29.9%) |
| Psychotherapy | 2,428 (27.3%) | 293 (12.1%) | 60.4 (10.6) | 7.43 (1.97) | 7.18 (1.82) | 54.6 (64.2) (29.0%) | 800 (33.0%) | 1.35 (1.63) (30.1%) | 1,386 (16.2%) | 701 (28.9%) | 1,128 (46.4%) |
| Movement skills-based | 5,687 (64.0%) | 518 (9.1%) | 62.6 (10.8) | 6.86 (2.11) | 6.40 (2.10) | 51.0 (63.3) (29.0%) | 1,641 (28.4%) | 1.38 (1.68) (31.0%) | 1,763 (16.2%) | 920 (23.6%) | 1,340 (23.6%) |
| Aerobic exercise | 3,548 (39.8%) | 362 (10.7%) | 62.1 (11.2) | 6.86 (2.11) | 6.24 (2.12) | 50.8 (62.5) (28.4%) | 1,007 (30.5%) | 1.30 (1.64) (30.1%) | 1,087 (15.5%) | 550 (23.8%) | 846 (23.8%) |
| Stretching/strengthening | 1,010 (11.7%) | 110 (0.9%) | 62.4 (10.9) | 6.86 (2.11) | 6.40 (2.10) | 50.8 (63.0) (28.4%) | 1,460 (30.5%) | 1.36 (1.67) (31.2%) | 1,291 (15.9%) | 570 (23.6%) | 1,000 (23.6%) |
| Yoga | 568 (6.39%) | 118 (20.8%) | 59.1 (12.1) | 7.14 (2.11) | 6.54 (2.07) | 53.7 (65.1) (29.9%) | 170 (28.8%) | 1.19 (1.54) (31.2%) | 217 (15.9%) | 126 (22.2%) | 177 (31.2%) |
| Tai chi | 402 (4.52%) | 46 (11.4%) | 63.1 (10.5) | 7.26 (2.08) | 6.56 (2.05) | 56.5 (64.4) (33.1%) | 133 (33.1%) | 1.50 (1.77) (38.1%) | 153 (19.4%) | 78 (30.4%) | 122 (30.4%) |
| Physical manipulation | 2,838 (31.9%) | 288 (0.82%) | 61.5 (11.7) | 7.01 (1.12) | 6.63 (2.05) | 51.6 (62.5) (28.8%) | 817 (30.5%) | 1.30 (1.64) (33.1%) | 939 (17.7%) | 503 (25.5%) | 722 (25.5%) |
| Acupuncture | 952 (10.8%) | 94 (0.25%) | 61.9 (11.6) | 7.17 (2.11) | 6.97 (1.92) | 57.1 (64.4) (34.5%) | 330 (36.8%) | 1.48 (1.73) (36.8%) | 352 (19.6%) | 188 (27.9%) | 267 (27.9%) |
| Chiropractic | 1,043 (11.4%) | 103 (14.0%) | 61.3 (12.4) | 7.08 (2.10) | 6.59 (2.05) | 47.6 (56.8) (27.3%) | 390 (37.1%) | 1.21 (1.55) (37.1%) | 317 (17.4%) | 212 (27.3%) | 447 (27.3%) |
| Massage | 1,727 (19.5%) | 201 (11.6%) | 60.9 (11.8) | 7.10 (2.11) | 6.57 (2.10) | 51.0 (62.7) (27.8%) | 482 (32.1%) | 1.24 (1.63) (32.1%) | 558 (18.0%) | 312 (25.7%) | 447 (25.7%) |

1. Number out of 10 possible bodily sites in which respondent was "bothered at all by pain" over preceding 6 months: head, teeth/mouth/jaw, neck, back, shoulder, hip, knee, foot/ankle/upper leg, stomach/abdomen, pelvic/genitals.

2. Brief Pain Inventory-Interference (BPI-I). Study population range 0-10, higher = worse.

3. MEDD: Morphine Equivalent Daily Dose, in milligrams. Study population range 0-1038.15.

4. Charlson comorbidity index. Study population range 0-13, higher = worse.

5. Post-traumatic stress disorder.

Characteristics of U.S. military veterans on long-term opioid analgesics reporting past-year use of non-pharmacological therapies for pain.

NON-VISIT-BASED AND NON-INFECTION-RELATED ANTIBIOTIC USE AMONG PRIVATELY INSURED PATIENTS DURING 2016-2018

Michael A. Fischer¹; Mufaddal Mahesri⁴; Joyce Lii²; Tiffany Brown³; Jeffrey A. Linder⁵. ¹Brigham & Women's Hospital, Boston, MA; ²Brigham and women's hospital, Boston, MA; ³Northwestern University Feinberg School of Medicine, Chicago, IL; ⁴Brigham and Women's Hospital, Boston, MA. (Control ID #3178400)

BACKGROUND: Appropriate antibiotic prescribing is an important goal for outpatient safety and quality improvement. Antibiotic prescriptions written outside of visits lack in-person clinician assessment, which may increase the risk of overuse. Similarly, when antibiotics are prescribed at a visit but no diagnosis of infection is documented then assessment of quality of care may be limited. We measured the frequency with which antibiotics were prescribed without an associated clinician visit or without an infection-related diagnosis in a large cohort of privately insured patients.

METHODS: We identified all filled antibacterial, antibiotic prescriptions from April 1, 2016 to June 30, 2018 by patients who were enrolled in a large private health insurance plan (OPTUM/Clininformatics). We identified all medical claims in the 7 days prior to the antibiotic prescription and defined a non-visit-based prescription (NVBRx) as occurring when the patient had no encounter with a clinician in those 7 days. We assessed whether the proportion of NVBRx differed by patient or antibiotic characteristics. We also examined whether the diagnosis codes for the clinician visits were for infectious conditions. Given the massive sample size - all comparisons were statistically significant - we considered differences of 5% clinically significant.

RESULTS: We identified 22.3 million filled antibiotic prescriptions, dispensed to a total of 8.6 million patients. Half of the prescriptions (52%) were dispensed to patients 17-64 years old and 61% were dispensed to female patients. For 6.9 million prescriptions (31%) there were no claims for clinician visits in the prior 7 days. NVBRx prescribing rates were not clinically different by gender (women, 30.7%; men, 31.3%), but were lower for children than for adults (0-17 years old, 15.9%; 18-64 years old, 32.8%; > 65 years old, 33.9%). NVBRx rates were considerably lower in the South than in all other regions (South, 22.5%, 31-34% in other regions). Among the 5 most commonly

prescribed antibiotic classes, the NVBRx rate was highest for penicillins (35.9%), followed by sulfa antibiotics (30.0%), quinolones (26.0%), cephalosporins (25.0%), and macrolides (24.7%). Of prescriptions associated with a clinician visit, 22% (4.9 million/22.3 million) were not associated with a diagnosis code for an infectious condition.

CONCLUSIONS: A large fraction of antibiotic prescriptions -millions in absolute terms- were filled without evidence of accompanying clinician visits. NVBRx occurred across the major classes of outpatient antibiotics, was more likely in adults, and occurred much less often in the South region. NVBRx may lack clinician assessment and, along with prescribing without an infectious diagnosis code, may increase the risk of adverse effects. Interventions should be developed to address these safety and quality concerns.

NOT YET STANDARD: USE OF STANDARDS FOR ADULT IMMUNIZATION PRACTICE AMONG PRIMARY CARE PHYSICIANS

Laura P. Hurley^{1, 2}; Sean T. O'Leary^{2, 5}; David K. Kim³; Lori A. Crane^{4,2}; Michaela Brtnikova^{2, 5}; Brenda Beaty²; Amy Parker Fiebelkorn³; Megan C. Lindley³; Allison Kempe^{2, 5}. ¹Denver Health, Denver, CO; ²Adult and Child Consortium for Health Outcomes Research and Delivery Science (ACCORDS), Aurora, CO; ³Centers for Disease Control and Prevention, Atlanta, GA; ⁴University of Colorado Anschutz Medical Campus, Aurora, CO; ⁵Children's Hospital Colorado, Aurora, CO. (Control ID #3165051)

BACKGROUND: In 2014 the National Vaccine Advisory Committee (NVAC) updated Standards for Adult Immunization Practice ("Standards") which consists of (1) assessing immunization needs at every visit, (2) strongly recommending needed vaccines, (3) administering vaccines or referring patients for vaccination, and (4) documenting receipt of vaccinations in an immunization information system (IIS). Our objectives were to 1) assess the extent of implementation of the Standards by primary care physicians and 2) describe the characteristics of primary care physicians who reported implementing the Standards.

METHODS: In December 2015-January 2016, we administered an Internet and mail survey to national networks of 480 general internist (GIM) and 455 family physician (FP) members of the American College of Physicians and American Academy of Family Physicians, respectively. Stocking was considered a proxy for administering. We performed multivariable logistic regression to examine associations between adhering to the Standards and demographic and practice characteristics.

RESULTS: Response rate was 68% for GIM (324/480) and 64% for FP (293/455). 32 % of GIM and 25% of FP had read the NVAC Standards. The majority of GIM (57%) and FP (54%) reported assessing immunization needs at every visit. Table 1 shows physician recommendations for, stocking of, and stocking or referring for several recommended adult vaccines. 27% of GIM and 46 % of FP reported documenting vaccinations in an IIS. 6 % of GIM and 11 % of FP reported adhering to all components of the Standards. Characteristics associated with adhering to all four Standards included FP specialty (OR 2.04, 95% CI 1.09-3.84) and having an electronic clinical decision support system to determine if a patient needs a seasonal influenza vaccine (OR 2.70, 95% CI 1.27-5.74).

CONCLUSIONS: While the majority reported stocking almost all recommended adult vaccines and several had read the Standards shortly after publication, very few primary care physicians are implementing all components of the Standards for routinely recommended adult vaccines. FP might be more likely to adhere to the Standards because they are more familiar with IIS as a result of using them for childhood vaccines. Development of electronic systems to support full implementation of the Standards may help improve adult immunization rates.

NOVEL RISK FACTORS FOR FALLS IN OLDER ADULTS EXPERIENCING HOMELESSNESS: RESULTS FROM THE HOPE HOME COHORT STUDY

Elizabeth Abbs¹; Rebecca Brown²; David Guzman¹; Claudia Ponath¹; Lauren M. Kaplan¹; Margot Kushel^{1, 1}. ¹University of California, San Francisco, San Francisco, CA; ²University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA. (Control ID #3180782)

BACKGROUND: The median age of homeless adults is increasing, with half 50 years. Homeless older adults are at high risk for developing geriatric conditions, including falls, prematurely. Despite high morbidity and mortality, little is known about risk factors for falls in this population. Among older adults, risk factors include individual factors (e.g. cognitive and functional impairment, sensory disabilities, alcohol use, and social isolation) and environmental factors (e.g. uneven surfaces, lack of lighting). People experiencing homelessness have a high prevalence of established fall risk factors and face complex environmental conditions. In addition, they have a high prevalence of potential novel risk factors, including living unsheltered, drug use, and physical assault. In a longitudinal cohort of homeless older adults, we examined the prevalence of and risk factors for falling.

METHODS: We recruited 350 homeless adults aged 50 in Oakland, California. We interviewed participants every 6 months for 3 years about falls, housing and shelter status, health status, health-related behaviors and social support. We assessed prevalence, frequency, and severity of falls. Using generalized estimating equations (GEE), we assessed risk factors for falling one or more times in the prior 6 months over the course of 3 years. In addition to established risk factors (race/ethnicity, sex, age, chronic diseases, functional status, urinary incontinence, use of assistive devices), we assessed potential novel risk factors (spending any nights unsheltered, illicit substance use, and experiencing physical assault).

RESULTS: Of the 350 participants, the majority were men (77.1%) and black (79.7%). The median age was 58 (IQR 54.0, 61). At the baseline interview, one-third (33.7%, 118) reported having fallen in the prior 6 months. Of those who fell, over one-quarter (28.0%, 33/118) experienced 4 or more falls and one-third (33.1%, 39/118) required medical evaluation. At study follow-up visits, between 23.1 to 31.2% of participants reported a fall. In GEE models, established risk factors (non-black race, women, older age, prior stroke, functional impairment, urinary incontinence, use of assistive devices) were associated with having fallen. In addition, novel risk factors, including spending any nights unsheltered, (AOR = 1.42, 1.10-1.83), cannabis use (AOR = 1.93, 1.47-2.55), opioid use (AOR = 1.64, 1.02-2.65), and experiencing physical assault (AOR = 1.67, 1.18-2.37) were associated.

CONCLUSIONS: Older homeless adults experience a high prevalence of falls. While established risk factors increase the odds of falls, environmental stressors and novel risk factors also contribute risk. Fall prevention efforts in older homeless adults should target those at highest risk. Interventions focused on modifiable risk factors, such as housing, exposure to violence, and substance use could reduce morbidity and mortality due to falls.

OBESITY, ANGIOTENSIN AXIS BLOCKADE AND ACUTE KIDNEY INJURY IN ORTHOPEDIC SURGERY

Matthew Hennrikus³; William Hennrikus⁴; Erik B. Lehman²; Katelyn McCann⁵; Eileen Hennrikus¹. ¹Penn State College of Medicine, Hershey, PA; ²Pennsylvania State University, Hershey, PA; ³Tulane University Medical School, New Orleans, LA; ⁴Walter Reed National Military Medical Center, Bethesda, MD; ⁵University of Massachusetts Medical School, Worcester, MA. (Control ID #3163103)

BACKGROUND: Acute kidney injury (AKI) occurs with a 7-11% incidence following adult orthopedic surgery. It remains controversial whether perioperative angiotensin axis blockade (AAB) with angiotensin converting enzyme inhibitor (ACEI) or angiotensin receptor blocker (ARB) drugs contributes to AKI. We examined the relationships amongst AKI, AAB, and obesity in orthopedic surgery.

METHODS: We reviewed the medical records of 1783 adult elective orthopedic surgery patients during the time period when patients were instructed to take their AAB drugs the morning of surgery. The primary outcome was postoperative AKI. A multivariable logistic regression was applied to statistically and clinically relevant variables in the entire group, an obese cohort ($BMI > 30$) and a non-obese cohort ($BMI < 30$).

RESULTS: Obesity increased the likelihood of developing AKI post-orthopedic surgery (odds ratio (OR) = 1.86, $p = 0.028$). The use of AAB increased the likelihood of developing post-operative AKI only in the non-obese cohort ($OR = 3.30$, $p = 0.030$). When ACEI and ARB were evaluated individually, only the ACEI in the non-obese patients had a statistically significant odds ratio of developing post-operative AKI ($OR = 3.49$, $p = 0.018$).

CONCLUSIONS: Obesity is an independent risk factor for AKI post-orthopedic surgery. Adipose tissue contains a complex renin-angiotensin system (RAS), functioning independently of systemic RAS. Adipose-associated RAS may contribute to the oxidative stress and inflammation induced by surgery, resulting in AKI. ARBs, by targeting the specific receptor involved in the oxidative and inflammatory pathway, may be protective of this stress. Non-obese patients, with low adipose RAS activity, who take preoperative ACEI appear to be more susceptible to AKI. Obesity and the different target receptors of ARBs vs. ACEIs may be contributing to the discordant findings in the literature regarding AAB in the perioperative patient

OBJECTIVE & SUBJECTIVE SOCIAL STATUS RELATE TO CANCER SCREENING BEHAVIOR

Daliz Cruz¹; Radhi Yagnik¹; Kezhen Fei¹; Emily J. Gallagher²; Nina A. Bickell¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3185395)

BACKGROUND: Objective and subjective measures of socioeconomic status (SES) are not interchangeable. Perceived SES (pSES) is associated with health status and behaviors independent of objective SES measures such as income and education. As many people refuse to answer survey questions about income, proxy measures may provide similar data. We assessed the relationship between breast cancer patients' perceived and objective SES with their cancer screening behaviors.

METHODS: Data were collected as part of a large prospective study evaluating the role of insulin resistance in women with newly diagnosed breast cancer. Patients were presented a ten rung ladder (The MacArthur Scale of Subjective Social Status tool that captures perceived SES) and were asked to place themselves where they stand in their communities. Low community pSES ranged from 1-8 and high pSES from 9-10. Objective SES measures included income and education; mammography and pap screening were assessed. Income $>\$100,000$ was classified as high income; education was dichotomized as college graduate. Comparisons used chi-square for categorical variables, t-tests for continuous variables. Logistic multivariate models were run.

RESULTS: Of 944 breast cancer patients with an average age of 57 ± 12.0 years, 81% were white and 19% black, 64% graduated college and 41% reported an income of $>\$100,000/\text{year}$. 18% of patients did not report an income. The median pSES= 8 (IQR: 7-8), 20% had high pSES (>8), and 80% had lower pSES (<8). There were no racial differences observed in pSES (high pSES: 21% black vs 20% white; $p=0.7$). More patients with high pSES graduated college (76% vs 61%, $p=0.0002$) and had income $>\$100,000/\text{year}$ (61% vs 36%, $p<0.0001$) than patients with lower pSES. Of the objective SES, patients with higher income ($>\$100,000/\text{year}$) were more likely to undergo both breast and cervical cancer screening (75% vs 58%, $p<0.0001$) as compared to patients with lower income ($>\$100,000/\text{year}$). There was no difference by college education on receipt of both breast and cervical cancer screening (66% vs 64%, $p=0.5$). Of perceived SES, patients with high pSES had higher breast and cervical cancer screening rates (78% vs 63%, $p=0.0002$) as compared to patients with low pSES.

CONCLUSIONS: Income and perceived SES are positively associated with cancer screening behaviors; education is not. Given some patients' reluctance to report income, perceived SES may offer an acceptable option to measure SES and its relationship to health behaviors.

OBSTRUCTIVE SLEEP APNEA AND PAIN INTENSITY AMONG VETERANS OF RECENT WARS

Wardah Athar^{2, 1}; Mary E. Card²; Antonios Charokopos²; Catherine G. Steffens¹; Kathleen M. Akgün^{2, 1}; Craig G. Gunderson²; Joseph L. Goulet¹; Eric C. DeRycke¹; Cynthia Brandt¹; Lori A. Bastian^{2, 1}. ¹VA Connecticut Healthcare System, West Haven, CT; ²Yale School of Medicine, New Haven, CT. (Control ID #3185867)

BACKGROUND: Both obstructive sleep apnea (OSA) and pain are highly prevalent among Veterans. While the specific link between OSA and pain remains unknown, research suggests that OSA patients experience hyperalgesia due to sleep fragmentation and/or hypoxia that enhances sensitivity to pain, promotes inflammation, and advances spontaneous pain. Further, OSA is associated with the development and progression of many painful conditions such as headaches, temporomandibular disorders, and fibromyalgia. Most studies examining the association of OSA and pain focused on older populations, necessitating further research concerning the relationship between OSA and pain among younger patients. This study investigates if those patients diagnosed with OSA are more likely to report moderate/severe pain intensity compared to those patients without OSA in a young cohort of Veterans of recent wars (Operations Enduring Freedom/Iraqi Freedom/New Dawn [OEF/OIF/OND]).

METHODS: We conducted a cross-sectional analysis of a cohort study of OEF/OIF/OND Veterans who had at least one visit to a Veterans Health Administration primary care clinic between 2001 and 2014. Diagnoses, including OSA, were identified using ICD-9 codes from electronic medical records. Current pain intensity, based on the 0-10 numeric rating scale, was categorized as no/mild pain (0-3) and moderate/severe pain (4-10), and we included only those pain scores recorded after an OSA diagnosis was made. Covariates included age, sex, race, mental health diagnoses (substance use, PTSD, depression, and anxiety), headache diagnosis, body mass index (BMI), and current or former smoking status. Multiple imputation was performed to generate values for missing variables.

RESULTS: We identified 858,226 Veterans in the OEF/OIF/OND cohort. The mean age was 30 years, 10.6% carried a diagnosis of OSA, and 32% reported moderate/severe pain intensity. Compared to Veterans without an OSA diagnosis, Veterans with an OSA diagnosis were more likely to report moderate/severe pain intensity ($OR = 1.26$; 95% confidence intervals 1.24-1.28), after controlling for covariates including: age, gender, race, substance use, major depression, post-traumatic stress disorder, headache diagnosis, smoking status, and BMI.

CONCLUSIONS: We discovered a clinically significant association between OSA diagnosis and pain intensity, showing that Veterans with OSA have greater odds of comorbid moderate/severe pain. Due to the high prevalence of chronic pain in younger Veterans, this study highlights the need to understand the impact of OSA diagnosis and treatment on pain intensity and to then develop interventions to identify and treat for OSA among Veterans with pain.

OLDER ADULTS' PERSPECTIVES ON HEALTH AND HEALTHCARE: A VIEW FROM PUBLIC HOUSING

Brooke R. Wagen; Elizabeth Jacobs; Whitney Williams. University of Texas at Austin, Austin, TX. (Control ID #3167188)

BACKGROUND: Geriatric health needs are projected to increase over the coming decades given demographic trends in the United States and the world. Many social service sectors have started strategizing how to address this trend, including public housing authorities. Recognizing the interplay

of housing and health, public housing authorities have a 'health in all policies' perspective, yet many have not fully investigated the needs of their older residents. In partnership with a local housing authority, we conducted a qualitative study to better understand older residents' concept of health and healthcare, including what helps them maintain health and wellness.

METHODS: We conducted semi-structured interviews with English and Spanish-speaking adults 65 years residing in one of two public housing complexes. Questions were designed to elicit resident's thoughts and perspectives on health, healthcare, housing, problem-solving, and community. Participants were recruited in person at each site with personal invitations and at resident council meetings. Interviews were conducted in participant's homes or private meeting places, audio-recorded, and transcribed verbatim. Spanish interviews were translated into English. We used grounded theory to analyze the data.

RESULTS: We interviewed 23 residents. They ranged in age from 65-85 years; 12 identified as Hispanic, 5 African American, and 6 non-Hispanic white; 43% were men. We identified multiple themes. First, older adults residing in public housing equate health with their ability to move and 'feel good'; the presence of multiple chronic conditions does not, for them, define health. Instead, they frame health questions in terms of what they are able to do for themselves, including choices in eating, moving, interacting with others, or following doctor's recommendations. Additionally, the majority stated they have no challenges in getting what they need for their health, despite the fact that all have three or more chronic diseases. They attribute the lack of challenge to provision of public health insurance for older adults and supportive services now available to them, highlighting the difference from when they were younger. Those who mentioned challenges focused primarily on money and transportation, especially out-of-pocket costs they can't afford.

CONCLUSIONS: We found that the older adult public housing residents in our study defined health as maintaining autonomy and mobility. Though socioeconomically limited, their approach to healthcare is independent; health challenges are framed in management terms with the self as the primary mover. Surprisingly, they identified few challenges to getting what they need for their health. Future efforts to improve older adult public housing residents' health should take into account their independence and resilience. Housing-health system partnerships that aim to impact this population will be best served by understanding their independent, management-oriented mentality.

ONLINE DECISION AID USE LEADS TO DESIRE FOR LESS AGGRESSIVE MEDICAL TREATMENT AMONG PATIENTS WITH ADVANCED CANCER

Michael J. Green¹; Lauren J. Van Scoy²; Andrew J. Foy¹; Anne Dimmock¹; Erik B. Lehman³; Theresa Smith¹; Benjamin Levi¹. ¹Penn State College of Medicine, Hershey, PA; ²Penn State University, Hershey, PA; ³Pennsylvania State University, Hershey, PA. (Control ID #3185851)

BACKGROUND: To help ensure that patients receive medical treatment consistent with their desires, advocates of advance care planning (ACP) encourage individuals to articulate their wishes for medical treatment in advance of illness. While many patients prefer less rather than more treatment at the end of life, in the absence of clear documentation to the contrary, the medical profession's default position is to provide *more* aggressive treatment. Directive videos can alter decisions, but it is not known whether a nondirective, robust, online educational decision aid can affect treatment choices.

METHODS: This was a secondary analysis of a single center, single-blind RCT of an advance care planning intervention among patients with Stage IV cancer. Participants were randomized to an Intervention Group (*Making Your Wishes Known*, a values-neutral, non-directive, multimedia online decision aid) or Control Group (standard living will form plus an educational brochure). Subsequently, participants were provided 6 clinical

vignettes and asked to indicate whether they would want or not want specific medical/surgical interventions in each situation. The primary outcome was participants' preferences for receiving 11 medical treatments (dialysis for < 1 month; dialysis for > 1 month; CPR; ventilator support for <24 hours; vent for up to 1 month; vent for > 1 month; feeding tube for up to 1 month; feeding tube for > 1 month; medicine; surgery; and transfusion). Data were analyzed by summing responses to the 11 questions about the paradigmatic vignette (a moderate/severe stroke that would not improve after 1 year). A total treatment preference score was calculated and the median number of desired treatments was compared between groups using a Wilcoxon Rank Sum test. Logistic regression was used to compare between-group likelihood of wanting each specific treatment.

RESULTS: 200 individuals participated in the study. Overall, participants in the Intervention Group desired fewer life-sustaining interventions than those in the Control Group. With the opportunity to choose as few as 0 and as many as 11 interventions, the median number of interventions desired was 1 in the Intervention Group versus 5 in the Control Group ($p < 0.001$). For 7 of the 11 specific interventions, the Intervention Group was significantly less likely than Control to want aggressive treatment. Most notably, compared to Control, Intervention Group participants were less likely to want: CPR (OR=3.2); short-term ventilator (OR=3.0); short-term dialysis (OR=2.6); surgery (OR=2.7); and transfusion (OR=2.6).

CONCLUSIONS: Individuals who use a robust, nondirective, educational ACP decision aid desire less aggressive medical treatment than those completing standard non-educational living will forms. These findings have implications not only for helping families and clinicians make end-of-life treatment decisions, but also potentially for reducing costs at the end of life.

ONLINE PORTAL USE BY ADULT GENERAL INTERNAL MEDICINE PATIENTS AT AN ACADEMIC MEDICAL CENTER

Alejandro Plana; Neda Laiteerapong. University of Chicago, Chicago, IL. (Control ID #3185800)

BACKGROUND: Patient portals have the potential to improve patient-provider communication, increase patient satisfaction with care, and augment the efficiency and quality of healthcare. However, failing to sufficiently account for the work required to respond to portal messages will lead to underinvestment in staff and increase the risk of provider and staff burnout. This study sought to describe portal use across a healthcare system by adult patients seen at an academic general internal medicine clinic and assess associations between patient portal use and patient characteristics.

METHODS: All healthcare encounters for any adult patient with at least one encounter at an urban, academic general internal medicine faculty practice between June 2014 to February 2018 were collected. Patients were categorized as MyChart users if they had at least one MyChart encounter. We compared sociodemographics between MyChart users and non-users using analysis of variance, chi-square tests, and multivariate logistic regressions.

RESULTS: During the 3.75-year period, there were 968,484 encounters from 59,973 unique patients. 24% (N=14,737) had at least one MyChart encounter and there was a mean 7283 MyChart encounters per year. 21% (N=12,346) patients had used MyChart to request medical advice. 6% (N=3,647) requested an appointment and 4% (N=2,559) patients requested a medication refill. Over half (55%) of MyChart users (N=7939) had 1 encounter. 3,668 patients (25%) had 2, 1,719 patients had 3 (12%), and 1,401 patients (10%) had 4 MyChart encounters. MyChart encounters were distributed across a total of 1671 healthcare providers; 1380 (83%) had completed 10 encounters, 174 (10%) had completed 10 to 50 encounters, 35 (2%) had completed 50-100 encounters, 43 (3%) had completed >100 MyChart encounters. In multivariate regression, patients >65 years were less likely (23.3%, 95% CI 22.0-24.6) and patients aged 35-50 years were more likely (33.0%, CI 31.9-34.0) to use MyChart than patients less than 35 years old (28.4%, CI 27.3-29.4). Men were less likely (14.7%, CI 13.8-15.7) than women (23.3%, CI 22.0-24.6) to use MyChart. Patients with

private insurance were more likely (23.3%, CI 22.0-24.6) than those with Medicaid (8.9%, CI 8.0-9.8) and Medicare (14.7%, CI 14.1-15.3) to use MyChart. Whites were more likely (43.1%, CI 41.5-44.9) than African-Americans (23.3%, CI 22.0-24.6), Asians (40.7%, CI 38.3-43.2), and patients of other ethnicities (25.3%, CI 23.3-27.3) to use MyChart.

CONCLUSIONS: Several vulnerable populations were less likely to use patient portals. Disparities in patient portal use may lead to significant differences in patient knowledge about their health and increased healthcare disparities in the future. In addition, patient portals contribute a large amount of work for physicians. Addressing the uncompensated work of patient portals is imperative such that primary care providers can provide high quality patient-centered care without increasing burnout.

OPIOD GUIDELINE ADHERENCE AND DOSE REDUCTION IN A RESIDENT SPECIALTY CLINIC FOR PATIENTS WITH CHRONIC PAIN

Laila Khalid¹; Serena Roth¹; Gianni Carrozza²; Chenshu Zhang¹; Aaron Burkenroad⁴; Joanna L. Starrels³. ¹Montefiore Medical Center, Bronx, NY; ²montefiore medical center, Bronx, NY; ³Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; ⁴ucla, Los Angeles, CA. (Control ID #3185612)

BACKGROUND: In response to the challenges of providing guideline-adherent care to patients with chronic pain, the Power Over Pain (POP) Clinic was developed to address the dual aims of training internal medicine residents about judicious opioid prescribing and providing guideline-adherent care for patients on chronic opioid therapy (COT). Objective: To determine whether being seen in POP Clinic was associated with receipt of guideline adherent care and opioid dose reduction after 6 months.

METHODS: We conducted a retrospective study in an urban internal medicine teaching practice in Bronx, NY. Eligible patients were seen in POP Clinic at least once between 9/1/16 and 4/1/18 and were on COT (3 opioid prescriptions in past 6 months). Using manual chart review of electronic medical records and prescription drug monitoring program (PMP) data, outcomes assessed at the first POP visit (baseline) and 6 months included four measures of guideline adherence: 1) controlled substance agreement in the past year, 2) urine drug test in the past year, 3) PMP review at last opioid prescription, and 4) dispensing of naloxone; and opioid dose (total prescribed opioid dose in morphine-equivalent daily dose [MEDD]). We used McNemar tests and paired t-tests to compare guideline adherence and opioid dose at 6 months compared to baseline.

RESULTS: Of 79 eligible patients, 67% were female, mean age was 59 years, 57% were Hispanic, 63% had back pain, mean PEG score was 7/10 (moderately severe pain), and 39% had multiple visits to POP Clinic (range 1-6). At baseline, median opioid dose was 70 MEDD (range 2-495). From baseline to 6 months, guideline adherence increased significantly for having a controlled substance agreement, urine drug test, and naloxone; and mean opioid dose was reduced by from 70.3 to 55.1 MEDD (Table). There was no significant change in PMP review, which was high (79%) at baseline.

CONCLUSIONS: For patients with chronic pain on COT seen in a resident clinic specialty session, guideline adherence increased and opioid dose decreased within 6 months. Further study is needed to assess how guideline adherence and dose reduction are associated with patient-level outcomes such as pain, function, and quality of life.

OPIOD OVERDOSES BEFORE AND AFTER PRESCRIPTION POLICY REFORM IN NORTHERN NEW ENGLAND

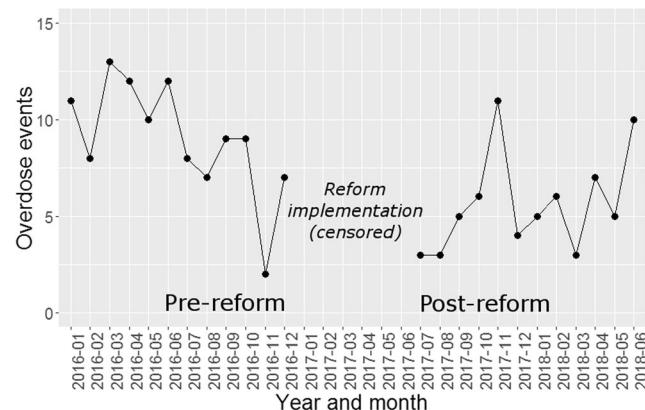

Timothy B. Plante¹; Insu Koh¹; Kathleen Fairfield²; Andrea Villanti¹; Valerie S. Harder³. ¹Larner College of Medicine at the University of Vermont, Burlington, VT; ²Maine Medical Center, Portland, ME; ³University of Vermont, Burlington, VT. (Control ID #3186410)

BACKGROUND: The opioid epidemic has disproportionately affected adults living in rural states. Northern New England states legislated comprehensive policies aiming to limit opioid overprescribing habits among primary care providers. Whether these reforms reduced overdoses among a primary care population is unknown. We sought to compare the incidence rates of opioid overdose events among primary care patients before and after opioid reform policies in Northern New England.

METHODS: We included structured electronic medical record data from 70,267 adults receiving primary care at University of Vermont Medical Center (UVMMC)-affiliated practices between January 1, 2016 and June 30, 2018 who were aged 18 years during follow-up. Vermont's opioid reform policies were implemented on July 1, 2017. As anticipatory UVMC policy changes preceded the enactment of the law, we considered the 6 months leading up to the law to represent the implementation of the policy and censored events in this time from the present analysis. We categorized time as pre-reform (January 1, 2016 - December 31, 2016; 12 months) and post-reform (July 1, 2017 - June 30, 2018; 12 months). We used ICD-9 and -10 codes to identify overdose events among inpatient and outpatient visits. We used Poisson regression to calculate the incidence rate ratios (IRR) to compare between time periods, adjusting for age, sex, race, and rurality status.

RESULTS: Among participants in the cohort (mean [SD] age 52 [19] years, 56% female, 92% white, 13% rural), there were 176 overdose events; 108 occurred in the pre-reform and 68 in the post-reform eras. In comparison with the pre-reform era, the adjusted IRR for post-reform was 0.62 (0.46, 0.85; P=0.002).

CONCLUSIONS: Among primary care patients at an academic health network in Northern New England, implementation of comprehensive policy reforms aiming to curb the overprescription of opiates was associated with a reduced incidence of opioid overdose. Whether a similar pattern is observed among patients without primary care providers requires further analysis.

OPIOD PRESCRIBING - UMASS INTERNAL MEDICINE PRIMARY CARE: ASSESSMENT OF BASELINE PRESCRIBING PATTERNS AND PROVIDER NEEDS. JEEVARATHNA SUBRAMANIAN MD, JASON SHAFFER MS2, SHERI A KEITZ MD, PHD, GERTRUDE MANCHESTER MD, PHOEBE CUSHMAN MD, MS.

Jeevarathna Subramanian. UMass Memorial medical Center, Shrewsbury, MA. (Control ID #3185664)

BACKGROUND: Central Massachusetts is one of the epicenters of the opioid crisis, Worcester County seeing an increase in opioid overdose deaths from 68 in 2000 to 226 in 2016. In 2017 Worcester was the only county in Massachusetts not to see a decrease in opioid overdose deaths. UMass Memorial Medical Center (UMMMC) is in the process of developing a standard approach for adherence to CDC guidelines on chronic

opioid prescribing. Towards that goal, we aimed to create an opioid registry, to characterize patterns of opioid prescribing, conduct needs assessment in opioid prescribing at UMass Benedict Internal Medicine (IM) Primary Care clinic.

METHODS: 1) Patient registry: Working with our Office of Clinical Integration we created an Epic-based registry, tracking patients who received at least three opioid prescriptions in a six-month period (12/22/2017 - 06/22/2018). We used the Massachusetts Prescription Awareness Tool (MassPAT) and Epic data to assess baseline prescribing patterns, including morphine milligram equivalents (MME) per day, co-prescribing of opioids and benzodiazepines, early refills (<28 days), presence of a pain agreement within the last year, urine toxicology testing within the last year, and presence of additional opioid prescribers. We maintained the registry as a secure password protected file 2) Needs assessment: We distributed a survey via SurveyMonkey to all 30 Benedict IM PCPs (26 MDs and 4 NPs), with responses on a scale of 1-4 and free text responses. We collapsed free text responses into themes.

RESULTS: We identified 450 long-term opioid users for whom we are primary prescribers. Eighteen percent received >60 MME/day, 25% received concurrent opioids and benzodiazepines, 22% received early refills. Of the 73 patients who received >60 MME/day, 53% did not have an updated pain agreement, 40% did not have a baseline urine toxicology. Majority of PCPs did not feel confident managing chronic non-malignant pain, identifying red flags for opioid misuse, interpreting urine toxicology results. Four main areas for which PCPs needed help were: choosing non-opioid options, following clinical guidelines, monitoring MassPAT, and managing challenging patients.

CONCLUSIONS: Baseline data demonstrate there is room for improvement with opioid prescribing patterns. With the creation of the electronic opioid registry, we have prescriber-level data and population-based approach towards improving opioid prescribing safety. We are working with IT analysts to allow the registry to be continually updated in real time. We will develop a multifaceted "peer support system" that centers around academic detailing, aiming to improve adherence to guideline. Our eventual goal is to disseminate our findings to other practices and contribute to a system-wide approach to opioid prescribing.

OPIOID PRESCRIBING BEHAVIORS AMONGST SOUTH CAROLINA OPIOID PRESCRIBERS

Samuel O. Schumann¹; Jingwen Zhang²; Justin Marsden¹; Patrick D. Mauldin¹; William P. Moran¹. ¹Medical University of South Carolina, Charleston, SC; ²MUSC, Charleston, SC. (Control ID #3186248)

BACKGROUND: Prescription opioids are the second leading cause of opioid-related death, and their non-medical use is a significant risk factor for transition to heroin use. Prescription Drug Monitoring Programs (PDMPs) allow prescribers, dispensers and regulators access to patient-level details on controlled substances to reduce abuse and promote safe prescribing. This report outlines Class II - IV opioid prescribing behavior in South Carolina (SC) from 2010 - 2017 using de-identified prescription data collected the SC PDMP (SCRIPTS).

METHODS: This retrospective study uses seven 12-month de-identified SCRIPTS data sets from 2010 - 2017. Indicators for opioid prescribing were defined by the Centers for Disease Control and Prevention as a part of their Prescription Drug Overdose Prevention for States surveillance program. *Rate of opioid prescribers* was defined as the number of prescribers who prescribe Class II - IV opioids on any one prescription in a given quarter divided by the number of total number of SC prescribers who prescribed any one Class II-IV medication in that same given quarter. *Rate of high-dose opioid prescribers* was defined number of prescribers with 90-morphine milligram equivalent (MME)/day prescribed on any one prescription in a given quarter divided by all prescribers who prescribed an opioid analgesic prescription identified in the numerator for the same given quarter. Tramadol and propoxyphene were excluded from the final analysis

RESULTS: Rate of opioid prescribers decreased from 75% in 2010 to 73% in 2017, while the absolute number of SC licensed prescribers who prescribed any Class II - IV medications remained. Rate of high-dose opioid prescribers decreased from 40% in 2010 to 27% in 2017. Percentage of high-dose opioid prescriptions also fell from 12.3% of all opioid prescriptions in 2010 to 9.6% in 2017.

CONCLUSIONS: Results show a decrease in the rate of opioid prescribers, high-dose opioid prescribers, and high-dose opioid prescriptions in SC from 2010 - 2017. This potentially signifies that either established SC prescribers stopped opioid prescribing or new SC prescribers were unwilling to prescribe opioids. While high-dose opioid prescribers fell by 13%, the percent of all opioid prescriptions that were high-doses only fell by 2.7%. This may indicate that patients are receiving high-dose opioids from a more concentrated pool of prescribers and reflects high-dose opioid tapering challenges. Rapid decreases in opioid prescribers should be monitored for unintended consequences, such as increases in transition to illicit opioids and accidental overdose. Future research should evaluate associated patient outcomes - including illicit drug use - and continue to monitor patterns of opioid prescribing. Special attention should be given to resource-poor areas of the state, which lack access to non-opioid pain management therapies, mental health services and medication assisted therapy providers.

OPIOID PRESCRIBING PATTERNS FOR CHRONIC NON-CANCER PAIN IN A PRIMARY CARE POPULATION

Alexander Chaitoff; Glen B. Taksler; Anita D. Misra-Hebert; Belinda Udeh; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #3185149)

BACKGROUND: In the midst of the opioid epidemic, guidelines and regulations are targeting outpatient opioid prescribing. While 50% of opioids are prescribed in primary care, prescription patterns within primary care populations have not been well explored. This study aimed to describe patterns in opioid prescribing to primary care patients with chronic non-cancer pain.

METHODS: This was a retrospective study using data extracted from the electronic health record at one large integrated health system in the United States. Participants were primary care patients with chronic pain, defined as self-reported pain lasting > 3 months on a routine pre-visit questionnaire, treated between January 2014 and December 2015. Patients with metastatic cancer were excluded. Opioid use was defined as receiving an outpatient opioid prescription. Opioids prescribed for at least two months in any three month period were classified as long-term. Opioid dose was measured in morphine milliequivalents per day (MME/day) averaged over each month a patient received a prescription. Predictor variables included demographic characteristics, pain severity measured using the numeric ranking scale-10, health insurance status, substance use behaviors, comorbidities, and receipt of non-opioid pain medications. Descriptive statistics were developed for pain medication use in the cohort. Multivariable regression models were used to explore the patient factors associated with receiving any opioid or a long-term opioid.

RESULTS: The sample included 24,127 patients with chronic pain. The sample had a mean age of 58.7 (standard deviation (SD)=15.3), and was majority female (64.4%, n=15,414) and White (77.4, n=18,668). Half of patients (56.3%, n=13,329) were prescribed an opioid. Patients received a median of 2 (interquartile range (IQR)=2-3) classes of non-opioid pain medications; 98.4% of patients who received an opioid also received another class of pain medication, and opioid users received more non-opioid pain medication classes than non-users (3 vs 2, p<0.001). Only 204 (0.8%) patients were prescribed an opioid continuously for 24 months. However, 6723 patients (27.9%) received long-term opioids, with an average dose of 12.4 MME/day (SD=44.43); 4.3% (n=289) had an average dose >50 MME/day. Age and race were not correlated with receiving an opioid. Females were more likely to receive an opioid (OR=1.06,

95%CI=1.01-1.12), but not long-term ($p>0.2$). Average pain severity was associated with receiving any opioid prescription (OR per point=1.20, 95%CI=1.18-1.22) and a long-term prescription (OR per point=1.23, 95%CI=1.22-1.25).

CONCLUSIONS: At one integrated health system, many patients with chronic pain received opioids, but few received continuous or high dose opioids, which may limit the impact of policies affecting prescribing in primary care. Patients receiving opioids also tried more non-opioid pain medications and reported higher pain severity, suggesting that opioids are reserved for difficult cases.

OPTIMAL TRIGGERS FOR PULMONARY EMBOLISM CLINICAL DECISION SUPPORT

Sundas Khan²; D'Arcy King²; Karina Calise¹; Vishwanath Anantramian²; Jeffrey Solomon²; Thomas McGinn². ¹Hofstra University, Manhasset, NY; ²Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY. (Control ID #3185959)

BACKGROUND: Pulmonary embolism (PE) is a high-risk disease and providers often overestimate a patient's risk and order unnecessary diagnostic tests. Clinical decision support (CDS) can help identify specific variables associated with a patient's risk. As part of a larger ongoing trial, our research team identified order entry as a trigger point for CDS to evaluate PE in the Emergency Department (ED) setting. An optimal trigger is defined as the ideal time in a physician's workflow where the tool will alert them to a patient's risk. Based on experience in usability testing that led to high provider adoption rates of CDS (60%), we hypothesized that ideal CDS would be flexible and trigger at multiple points. The aim of the study was to conduct usability testing on two different prototypes of a CDS tool based on the Wells' criteria which would present earlier in the clinical decision-making process.

METHODS: Two prototypes included a triage note and a pop-up agent; both consisted of a calculator, order set, and recommendations. Usability testing was conducted with a total of 7 participants, 3 ED physicians and 4 triage nurses, at a tertiary care center within a large health system to evaluate the optimal design. The nurses and physicians were each asked to complete both versions of the tool. Following the completion of the tool, the study team conducted a debriefing session which included: the need for conversation between physician and nurse after using the tool, the amount of information provided by the tool, and if there were any interruptions in the clinical workflow. Following the session, the validated system usability scale (SUS) was administered for each version of the prototype to provide a basis for objective comparison.

RESULTS: Based on the SUS, providers and nurses cumulatively preferred the pop-up agent more (76.7%) than the triage note (69.4%). The positive comments for the pop-up agent prototype were that it helped providers get a quick recap on the patients' histories, it was easier to read, and centralized placement helped with easier navigation. The main negative comments for the triage note prototype was that it was not useful in a fast-paced environment such as the ED, content of the triage note was not unique, and to change the location of the note. Overall, providers stated that the tool would give them confidence in making decisions regarding the patient's treatment.

CONCLUSIONS: Usability testing was conducted on two CDS prototypes that triggered earlier in the clinical workflow than previous CDS. The pop-up agent was ranked higher and more effective as it had a different interface than the regular electronic health record, and it was a more user-friendly tool ultimately leading to increased utilization of the tool by providers. It is important for triggers to alert physicians at an optimal time with a user-friendly design. Our second phase of testing will be to compare the pop-up agent trigger to the order entry trigger.

OPTIMIZING CANCER SCREENING IN WOMEN WHO WANT SOME, BUT NOT ALL, GUIDELINE-RECOMMENDED SCREENINGS

Glen B. Taksler^{1, 1}; Elisabeth F. Peterse²; Isarah T. Willem²; Kevin ten Haaf²; Erik Jansen²; Inge de Kok²; Nicolen T. van Ravesteyn²; Harry J. de Koning²; Iris Lansdorp-Vogelaar². ¹Cleveland Clinic, Cleveland, OH; ²Erasmus Medical Center, Rotterdam, Netherlands. (Control ID #3180304)

BACKGROUND: Middle-aged women often want breast and cervical cancer screenings but are hesitant to obtain colorectal and lung cancer screenings. We sought to evaluate how providers might best advise women on strategies to prevent overall cancer-specific mortality while still limiting screenings to 1-2 per year.

METHODS: We modeled a cohort of females aged 50 y with characteristics representative of the US population, utilizing 4 validated microsimulation models developed as part of the National Cancer Institute's Cancer Intervention and Surveillance Network (CISNET). We examined 45 strategies combining breast, cervical (PAP and HPV co-testing), colorectal (fecal immunochemical testing [FIT]) and/or lung cancer screenings where women obtained some, but not all, screenings recommended by the US Preventive Services Task Force (USPSTF) over their lifetimes. The primary outcome was life-years gained from all cancer screenings relative to full compliance with USPSTF recommendations ("optimal benefits"). Results were stratified by eligibility for lung cancer screening ("eligible/ineligible") and, proxying for overall interest in cancer screening, a woman's preference for cancer screening intensity (number and frequency of screenings).

RESULTS: Among women ineligible for lung cancer screening, the USPSTF recommended 3 cancer screenings: annual FIT, biennial mammography and cervical cancer screening every 5 years. Breast and cervical cancer screenings conferred only 48% of optimal benefits. However, women who were willing to introduce FIT could obtain just 1 screening/year and keep up to 88% of optimal benefits. The top-ranked strategy was alternating FIT and mammography, and omitting cervical cancer screening for ages 50 y. Among eligible women, lung cancer screening was essential; strategies omitting it provided 25% of optimal benefits. For these women, the USPSTF recommended annual lung and FIT, biennial mammogram and cervical cancer screening every 5 years until age 65 y. Breast and cervical cancer screenings provided only 12% of optimal benefits. Yet, just 2 screenings/year could provide up to 98% of optimal benefits. The top-ranked strategy was annual lung, alternate FIT and mammography, but skip every 3rd mammogram (i.e., every 6th year) for cervical cancer screening until age 65 y. For eligible women who only wanted 1 cancer screening/year, the top-ranked strategy was annual lung (omitting all other screenings), affording 73% of optimal benefits. Sensitivity analyses were robust to receipt of colonoscopy instead of FIT, smoking history, cervical cancer screening history and background colorectal cancer risk.

CONCLUSIONS: Women who do not want all guideline-recommended cancer screenings may be able to reduce screening intensity with minimal impact on overall benefits. However, colorectal cancer screening and (if eligible) lung cancer screening were essential. Providers might consider these results as part of a holistic cancer screening discussion.

OPTIMIZING DISCHARGE SUMMARIES: A MULTISPECIALTY, MULTI-CENTER SURVEY OF OUTPATIENT PROVIDERS

Jason Higdon¹; Aaron M. Silver²; Leigh Anne Goodman²; Romil Chadha³; Michael Burton⁴; Venkataraman Palabindala⁵; Nageshwar Jonnalagadda⁶; Abey Thomas⁴; Christopher M. O'Donnell⁷. ¹Emory, Atlanta, GA; ²Banner University Medical Phoenix, Phoenix, AZ; ³University of Kentucky, Lexington, KY; ⁴UT Southwestern, Dallas, TX; ⁵University of Mississippi Medical Center, Jackson, MS; ⁶Baystate Health, Longmeadow, MA; ⁷Emory University, Atlanta, GA. (Control ID #3182996)

BACKGROUND: Hospital discharge is a complex and dangerous process. The emergence and rapid growth of the Hospitalist specialty with the simultaneous decline of traditional practice models complicates discharges. In light of the discontinuity, it is crucial to build reliable communication tools that facilitate transmission of critical information. The discharge summary is an essential piece of that transition and is often the only means of communication between the hospital and the outpatient provider. A well written, thorough, accurate, and timely discharge summary may help to prevent 30-day hospital re-admissions. Although the Joint Commission and the Center for Medicare and Medicaid Services both published guidelines for the structure of discharge summaries, it is unclear how outpatient providers use this information. In addition, formal training surrounding discharge summaries within residency programs has traditionally been lacking. Many studies demonstrate frequent inaccuracies or missing components from discharge summaries. They often lack information that outpatient providers may find most useful (e.g. reasoning behind medication changes) and are not completed prior to the post-hospital visit.

METHODS: To further delineate the most useful elements of discharge summaries, we conducted a multi-center, multi-specialty survey of Internal Medicine, Family Practice, and Pediatric practitioners that assessed providers' preferences and how they utilized these resources.

RESULTS: In descending order, outpatient providers considered the hospital course, medications, discharge diagnoses, follow-up instructions, and HPI to be the most important components of discharge summaries. Labs and radiology were less important while weight bearing status, wound care, ancillary services, and consults were ranked lowest. Most outpatient providers read the summary the day of the appointment and 60% of respondents said it was the only source of communication with inpatient providers.

CONCLUSIONS: Using this information, it is feasible to create a standardized template that will increase efficiency of both hospitalists and outpatient providers and help to safely transition care. The most crucial elements that should be prioritized at the beginning of the summary are hospital course, complete medication list, discharge diagnoses, and history of present illness. Based on this large data set, we strongly believe that the creation of a standardized discharge summary template will lead to a more efficient and effective discharge process, with fewer readmissions and safer transition out of the hospital.

OPTIMIZING MEDICAL STUDENT LEARNING EXPERIENCES ON HOSPITAL MEDICINE TEAMS-A QUALITATIVE STUDY

Yogita Segon; Ankur Segon; Sun Young Jeong; Riley Westein; Michael Gehring. Medical College of Wisconsin, Brookfield, WI. (Control ID #3185888)

BACKGROUND: As the landscape of healthcare changes, hospitalists are progressively at the fore front of medical training as educators for both students and residents. There is some literature suggesting that hospitalists are rated favorably by both house staff and medical students as better clinical educators on inpatient internal medicine rotation as compared to traditional non-hospitalist faculty. Some studies have raised concerns about possible negative impacts on autonomy and decision making, bedside teaching and subspecialty exposure of housestaff. However, impact of hospitalists on medical student education has received relatively less attention. Our study focuses on the educational experience of medical students and hospitalists on general inpatient hospitalist teams that are comprised of a hospitalist attending and advanced practice provider along with one to two medical students.

METHODS: This qualitative project involved one-on-one interviews with eleven third year medical students and seven hospitalist physicians who worked on a hospitalist service in last one year. A team of three third year medical students was deployed as interviewers to minimize pressure

on student interviewees. Hospitalist physicians were interviewed by the author (hospitalist attending). Verbatim transcription was performed by three medical students and the author. All data was coded and analyzed by the author via thematic analysis.

RESULTS: Multiple themes emerged from these interviews. Student interviews generated themes around the ideal structure and content of rounds. In addition, student perceptions around the impact of attending and team-based variability on learning experiences were elucidated. The hospitalist attendings interviewed opined on barriers to providing a better learning experience for students. In addition, several learner and rotation based changes to optimize student experience were suggested by the hospitalists.

CONCLUSIONS: Data collected so far suggests that students appreciate variability in different attending's style of working and teaching and are willing to adapt as long as expectations are discussed beforehand. They really value dynamic feedback. The hospitalist attendings perceived high patient census as the biggest barrier to providing better learning experience for students. Changes recommended by them included more proactive involvement of students in the logistics of patient care and a desire for a set of recommended best practices to optimize learning experiences on hospitalist teams.

OUTCOMES OF INTENSIVE CARE MANAGEMENT FOR VETERANS AT HIGH RISK FOR HOSPITALIZATIONS IN YEAR 2

Evelyn T. Chang^{1, 5}; Jean Yoon²; Donna M. Zulman³; Lisa V. Rubenstein⁴; Michael Ong^{5, 1}; Susan E. Stockdale⁶; Angel Park²; Elvira E. Jimenez⁶; David Atkins⁷; Angela Denietolis⁹; Steven Asch⁸. ¹VA- Greater Los Angeles, Los Angeles, CA; ²Palo Alto VA, Menlo Park, CA; ³Stanford University and VA Palo Alto, Stanford, CA; ⁴RAND and UCLA, Medford, OR; ⁵UCLA, Los Angeles, CA; ⁶Greater Los Angeles VA Healthcare System, Sepulveda, CA; ⁷Veterans Health Administration, Washington DC, DC; ⁸VA/Stanford, Menlo Park, CA; ⁹Primary Care, Veterans Health Administration, Washington, DC, DC. (Control ID #3184217)

BACKGROUND: Like many healthcare systems, the Veterans Health Administration (VHA) is piloting programs to intensify primary care for patients at high risk for hospitalization. VHA operational leaders partnered with five demonstration sites and an evaluation team in a quality improvement initiative to determine whether augmenting primary care in a standard medical home model (called Patient Aligned Care Team, PACT) with Primary care Intensive Management (PIM) decreases healthcare costs. Thus far, PIM was cost-neutral in the first year; we further investigated health care costs in the second year after the intervention began to assess for potential cost-savings during Year 2.

METHODS: PIM programs included an interdisciplinary team, comprehensive patient assessment and evaluation, transitional care management, and care coordination services. We drew a random sample of 2210 Veterans who were at top 10th percentile of risk for 90-day hospitalization based on a validated VHA risk algorithm and allocated half to PIM (n=1105). We excluded patients not either seen in a VHA emergency department visit or hospitalized during the past six months. We used an intent-to-treat design to compare the change in mean VHA inpatient and outpatient utilization and costs (including PIM expenses) per patient for the 12-month period before allocation and 12-month period at 13-24 months after allocation. We performed difference-in-difference regression analyses to detect changes in utilization and costs (using fixed effects adjusting for patient-level covariates).

RESULTS: PIM was associated with an increase in primary care (p<0.001), care management (p<0.001), telehealth (p=0.002), mental health and substance use (p=0.01), and home care p=0.01) encounters, both in person and by telephone, compared to usual care in PACT. PIM was associated with a decrease in triage (p=0.02) and mental health assertive community treatment (p=0.03) encounters compared to usual care in PACT. There was no significant difference in ED visits (p=0.68). The mean costs of

outpatient care in Year 2 were similar in the two groups (\$19,609 [CI \$18,621, \$20,596] for PIM; \$17,707 [CI \$16,586, \$18,827] for usual care; p=0.12). There was no significant difference in mean hospitalizations (p=0.17) and inpatient costs in Year 2 (\$16,175 [CI \$10,896, \$21,455] for PIM; \$15,027 [CI \$11463, \$18,592] for usual care; p=0.79). Total mean health care costs were similar between the two groups during Year 2 (p=0.47).

CONCLUSIONS: Current intensive care management approaches that target patients solely based on high risk of hospitalization like PIM may increase primary care and mental health services. However, they are unlikely to reduce acute care use in VHA, a setting with a robust patient-centered medical home model. Additional work is needed to develop strategies to identify a subset of high-risk patients whose admissions are truly preventable and to design the strategies that will prevent them.

OUTCOMES OF PERSONALIZED VERSUS GUIDELINE-BASED BREAST CANCER SCREENING: A SIMULATION MODEL

Yiwey Shieh¹; Laura J. Esserman¹; Martin Eklund². ¹University of California, San Francisco, San Francisco, CA; ²Karolinska Institutet, Stockholm, Sweden. (Control ID #3180851)

BACKGROUND: Breast cancer screening is costly and resource-intensive, yet current guidelines disagree on the optimal starting age and timing of screening. Personalized screening, or screening tailored to individual breast cancer risk, has been proposed as an improvement on guideline-based screening. WISDOM (Women Informed to Screen Depending on Measures of Risk) is an ongoing randomized trial comparing personalized to annual screening. To project the population-level outcomes of personalized screening, we constructed a simulation model comparing personalized to guideline-based screening strategies across advanced (Stage IIB+) cancers, false positives, negative biopsies, and cost.

METHODS: Our simulated cohort included 100,000 women aged 40-74 with demographic and risk factor distributions based on the U.S. screening population. We modeled the WISDOM approach to personalized screening where recommendations are based on the results of genetic mutation testing and 5-year risk estimates from a clinical risk model modified by a polygenic risk score containing 76 genetic variants. Each simulated woman was randomly assigned a clinical and genetic risk profile, which were used to generate a 5-year risk estimate. This was then used to assign a starting and stopping age, frequency, and modality (MRI vs. mammogram) of screening. We compared the aggregate outcomes over a 1-year time window between personalized screening and 3 strategies based on U.S. professional society guidelines (Table).

RESULTS: All screening strategies resulted in similar rates of advanced cancers (Table). However, the biennial, hybrid, and personalized strategies resulted in fewer false positives and biopsies compared to annual screening, and at lower cost. Though aggregate outcomes were similar between the hybrid and personalized strategies, the average 5-year risk of women assigned to biennial screening was lower under the personalized strategy, 1.4% vs. 2.0%. Similarly, the average 5-year risk of women recommended for adjunctive MRI under the personalized strategy was higher than that of the hybrid strategy, 10.4% vs 4.2%.

CONCLUSIONS: Personalized screening results in a similar incidence of advanced cancers as annual screening while reducing false positives, negative biopsies, and cost. Compared to other guideline-based strategies, personalized screening better allocates screening resources by identifying higher-risk women for more intensive screening, and lower-risk women for less intensive screening.

OUTPATIENT TRANSTHORACIC ECHOCARDIOGRAM REFERRAL PRACTICES: INDICATIONS AND PREVALENCE OF FINDINGS

Patrick Miller; Michael Yang; Monvadi B. Srichai. MedStar Georgetown University Hospital, Washington, DC. (Control ID #3185605)

BACKGROUND: Transthoracic echocardiography (TTE) is a widely used tool, and often the first imaging test performed for evaluation of patients with signs or symptoms suggestive of underlying cardiac disease. However, there is a paucity of epidemiologic data describing ordering practices and echocardiographic findings among these patients in the primary care setting. This study aims to characterize the most common indications for TTE referral in the outpatient setting, and the prevalence of significant findings in patients without a known history of heart disease.

METHODS: This was a retrospective, single center study. Consecutive outpatient TTE order requisitions were reviewed from 10/1/18 to 11/6/18. We included patients without cardiac history referred for specific clinical questions, including abnormal electrocardiogram (EKG), chest pain, dyspnea, edema, murmur, and hypertension. We excluded those referred for stress test, chemotherapy, pre-operative assessment, or follow-up of known cardiac disease including cardiomyopathy or valvular disease. Data were collected on ICD-10 code indication, past medical history, and relevant data from TTE final report.

RESULTS: Of 259 TTEs reviewed, 91 met inclusion criteria with 37.4% men, 62.6% female and a mean age of 54.4 years at the time of study. The most common indication was abnormal EKG in 20 patients (22.0%). The next most common indications were dyspnea (13.2%), palpitations (7.7%), murmur (7.7%), edema (7.7%), syncope (6.6%), hypertension (5.5%), and chest pain (5.5%). Eighty-three patients (91.2%) had normal left ventricular (LV) function, including 72 (79.1%) patients with completely normal TTEs. The most common abnormal finding was valvular disease (9.9%), followed by decreased LV systolic function (8.8%). See Table.

CONCLUSIONS: At our institution, outpatients without cardiac history are most commonly referred for TTE due to abnormal EKG. Of those referred for TTE, the prevalence of abnormal findings was 20.9%. The most common abnormal finding was valvular disease.

Prevalence of Disease for Outpatient TTE 10/1/18 to 11/6/18

| TTE Finding | # | Prevalence |
|---|------------|--------------|
| Normal LV Function | 83 | 91.2% |
| Valvular Disease | 9 | 9.9% |
| AV Thickening | 4 | 4.4% |
| MV Thickening | 2 | 2.2% |
| Mod-Sev AS | 1 | 1.1% |
| Mod-Sev AR | 1 | 1.1% |
| Mod-Sev MR | 1 | 1.1% |
| Mod-Sev MS | 0 | 0.0% |
| Abnormal LV Function | 8 | 8.8% |
| LVEF 40-50% | 6 | 6.6% |
| LVEF 30-40% | 2 | 2.2% |
| LVEF <30% | 0 | 0.0% |
| LV Wall Motion Abnormalities | 4 | 4.4% |
| Abnormal RV Size | 4 | 4.4% |
| Abnormal RV Function | 3 | 3.3% |
| Abnormal LV Size | 1 | 1.1% |
| Pericardial Effusion | 1 | 1.1% |
| RV WMA | 0 | 0.0% |
| # of Patients w/ any Abnormality | 19 | 20.9% |
| Total # of Patients | 91 | |
| Total # of Findings | 113 | |

Note: # of findings is greater than total # of patients bc some patients have more than one finding

OUTREACH TO PROMOTE MANAGEMENT OF CARDIOVASCULAR RISK IN PRIMARY CARE AMONG RHEUMATOID ARTHRITIS PATIENTS SEEN IN RHEUMATOLOGY PRACTICE

Dawid Lipiszko¹; Ji Young Lee¹; Darcy Majka²; Yaw A. Peprah¹;

Michael Schachter³; Eric Ruderman^{1, 3}; Stephen Persell^{1, 3}.

¹Northwestern University, Evanston, IL; ²DuPage Medical Group, Westmont, IL; ³Northwestern Memorial Healthcare, Chicago, IL.

(Control ID #3182867)

BACKGROUND: Cardiovascular disease (CVD) is the leading cause of death in rheumatoid arthritis (RA) with CVD risk increased 1.5-2.0-fold above the general population. Despite recommendations for aggressive risk factor management in RA, physicians identify and manage cardiovascular risk factors less often in RA patients compared to patients without RA. Previously, we tested a multifaceted quality improvement intervention consisting of clinician education, clinical decision support at the point-of-care, performance measurement and feedback to rheumatologists, and individualized mailed recommendations to patients to measure CVD risk factors and to address hypertension, cholesterol treatment, or smoking when applicable. This combined intervention led to considerable increases in the proportion of RA patients with all major CVD risk factors assessed but did not lead to significant improvements in CVD risk factor management or control. Therefore, we added a proactive outreach intervention aimed at promoting primary care treatment of CVD risk factors among RA patients to an existing set of interventions in order to attempt to improve primary care treatment of CVD risk factors in RA patients. We tested the impact of this strategy among RA patients identified through their rheumatology practice.

METHODS: Through electronic health record searches, we identified RA patients who were potential candidates for hypertension treatment initiation or intensification, statin therapy (based on age and risk) or a smoking cessation intervention. A non-clinician care manager contacted RA patients by phone and mail on behalf of the patients' rheumatologists, provided information about the identified CVD risk factor(s), recommend follow up with primary care physicians (PCPs), sent correspondence to PCPs, and followed up with patients approximately 4 weeks later to see what actions had been taken or barriers encountered. Information was shared with the patient's rheumatologist via EHR. We repeatedly measured preventive cardiology quality indicators from electronic health record data and compared pre-intervention to intervention time periods using interrupted time series methods.

RESULTS: During the 6-month intervention period, the proportion of RA patients age 40 to 75 prescribed a statin rose from 18.4% to 23.8%, and the rate of increase was significantly greater than during the preceding time period (1.06 percent per month greater than the prior period, $P<0.001$). Rates of increase in hypertension diagnosis and control also improved more rapidly during the intervention time period (1.05 and 2.09 percent per month greater, $P<0.001$ for each) and reversed preceding negative trends.

CONCLUSIONS: Implementing proactive non-clinician phone and mailed outreach to encourage primary care-based treatment of CVD risk factors was associated with measurable increases in statin prescribing, hypertension diagnosis, and hypertension control. Smoking was not affected.

OVERDOSE IS COMMON AMONG HOMELESS-EXPERIENCED VETERANS: NEW NATIONAL SURVEY DATA

Stefan Kertesz^{1, 4}; Adam Gordon^{2, 3}; Aerin DeRussy¹; April E. Hoge¹; Ann E. Montgomery¹; Kevin R. Riggs^{1, 4}; Sally Holmes¹; Erika L. Austin¹; Lillian Gelberg^{5, 6}; Sonya Gabrielian^{5, 6}; Allyson Varley^{1, 4}; Adiseshu Gundlapalli^{2, 3}; Young-il Kim^{1, 4}; Audrey Jones³. ¹Birmingham VA Medical Center, Birmingham, AL; ²VA Salt Lake City Health Care System, Salt Lake City, UT; ³University of Utah, Salt Lake City, UT; ⁴University of Alabama at Birmingham, Birmingham, AL; ⁵VA Greater Los Angeles Health Care System, Los Angeles, CA; ⁶UCLA, Los Angeles, CA. (Control ID #3184324)

BACKGROUND: Overdose (OD) is a frequent cause of death among homeless individuals. Prevention of overdose in primary care (PC) could depend on identifying people who have survived or witnessed OD. We measured the prevalence of both events among homeless-experienced veterans (HEVs) in primary care and assessed risk factors for overdose in the largest survey of HEVs conducted to date.

METHODS: A stratified, random sample of 5,666 homeless-experienced users of Veterans Administration primary care services was recruited for survey through sequential mailings (pre-notification letter, survey, postcard reminder) followed by telephone outreach (recruitment pool 14,352, with 40% response rate). The survey queried OD "where you needed to go to the emergency room or get medical care right away" in the past 3 years, and separately, witnessing such an event. Additional items assessed current homelessness, substance use problems based on the Two-Item Conjoint Screener, and validated measures for social support, mental distress, chronic pain, receipt of psychiatric medication, count of medical conditions, and general self-reported health. Bivariate analyses (chi-squared and t-tests) and multivariable logistic regression were used to identify characteristics associated with self-reported overdose.

RESULTS: Among HEVs, 15.1% ($n=869$) reported witnessing an OD and 6.6% ($n=378$) reported experiencing OD. The latter (ODs experienced) more commonly involved alcohol (3.4% of total, 51% of ODs) than drugs (2.6%); however, 1.4% didn't endorse a substance, and 0.7% endorsed both alcohol and drugs. Among drugs, opioids were reported by 1.4% (22% of all ODs), and cocaine by 1.0% (15%). The following differences were significant at $p<0.001$: Persons reporting OD were more likely than those without OD to be white (54.2% vs 40.9%), currently homeless (20.4% vs 12.4%), to receive psychiatric medication (57% vs 33%), and to have witnessed another person OD (37% vs 14%). Additionally, patients with OD reported higher mental distress (11.0 vs 6.8, scale 1-24), lower social support (3.8 vs 4.3, scale 0-6), and a greater prevalence of alcohol (55% vs 26%) and drug problems (31% vs 12%). In multivariable-adjusted models, characteristics associated with overdose included: white race (Odds Ratio, OR=2.3), current homelessness (OR=1.4), receipt of a psychiatric medication (OR=1.7), elevated mental distress (OR=1.1 for +1-point on 24-point scale), and having witnessed overdose (OR=2.5); all p 's<0.05.

CONCLUSIONS: Compared to samples suggesting that 0.01-0.1% of adults have experienced overdose, HEVs in PC report high rates of OD, and 1 in 7 report having witnessed OD. Opioids are present in nearly ¼ of these events and alcohol in over ½.

These survey data suggest that PC providers for homeless-experienced persons may have a powerful opportunity to mitigate overdose risk in their patients by addressing polydrug, alcohol and prescription exposure, and to explore protection of others at risk in the patient's environment.

OVERLAP BETWEEN MEDICARE'S ACCOUNTABLE CARE ORGANIZATIONS AND BUNDLED PAYMENTS

Joshua M. Liao^{4, 1}; Sarah Dykstra³; Rachel M. Werner^{1, 2}; Amol S. Navathe^{1, 2}. ¹University of Pennsylvania, Philadelphia, PA; ²CMC VA Medical Center, Philadelphia, PA; ³The Wharton School, University of Pennsylvania, Philadelphia, PA; ⁴University of Washington, Seattle, WA. (Control ID #3179510)

BACKGROUND: Accountable care organizations (ACOs) and bundled payments represent cornerstone payment models of Medicare's strategy to improve the value of care. As both models grow in prominence and scale, participating organizations in each may increasingly provide care to the same beneficiaries, posing important clinical and policy implications. However, no data about the magnitude and trend in overlap between ACOs and bundled payments exist.

METHODS: Using 100% 2013-2016 institutional Medicare claims, Medicare Shared Savings Program (MSSP) ACO beneficiary attribution, and hospital participation data for the Bundled Payments for Care Improvement (BPCI) initiative, we identified care episodes for beneficiaries attributed to MSSP ACOs and receiving care at BPCI hospitals for its 48 (25 condition-focused, 23 procedure-focused) episodes. For each episode, we defined 3 beneficiary groups: those attributed to MSSP who were hospitalized for an episode at BPCI hospitals participating in that episode (*Overlap*); those attributed to MSSP who were hospitalized for that episode at non-BPCI hospitals (*MSSP-only*); and those hospitalized at BPCI hospitals for a BPCI episode but who were not attributed to MSSP (*BPCI-only*). Medicare and US Census Bureau data were used to compare 246,392 *Overlap*, 2,824,898 *MSSP-only*, and 702,864 *BPCI-only* episodes with respect to sociodemographic, clinical and utilization characteristics. Categorical and continuous variables were compared using ² tests and *t* tests, respectively. Statistical tests were 2-tailed and significant at =0.05.

RESULTS: The number of MSSP ACOs increased from 220 in 2013 to 432 in 2016. The number of BPCI hospitals increased from 9 to 389 over this period, peaking at 413 in 2015. Across episodes, *Overlap* patients were generally lower severity, though differences were small. The overlap as a share of ACO patients increased from 2.7% at the start of the study period to 10% at the end of 2016 across all clinical episodes, while overlap as a share of all bundled payment patients increased from 19% to 27%. Overlap as a share of ACO patients varied by episode, ranging by the end of 2016 from 3% for acute myocardial infarction and chronic obstructive pulmonary disease to 18% for automatic implantable cardiac defibrillator, and was greater for procedure-focused (13%) than condition-focused (9%) episodes. Similarly, overlap as a share of bundled payment patients was greater for procedure-focused (29%) versus condition-focused (26%) episodes, varying overall from 21% for spinal fusion episodes to 32% for lower extremity joint replacement and automatic implantable cardiac defibrillator episodes.

CONCLUSIONS: In the first description of overlap between ACOs and bundled payments, one in every ten MSSP patients received care - and in particular procedural care - under BPCI by the end of our study period, while over one in every four patients receiving care under BPCI was also attributed to MSSP.

OVERVIEW OF THE CLINICAL DEVELOPMENT OF FREMANEZUMAB

Stephen D D. Silberstein¹; David W. Dodick²; Joshua M. Cohen³; Ronghua Yang³; Melissa Grozinski-Wolff³; Xiaoping Ning³; Sissy Easo-Joseph³; Lindsey Noble³. ¹Jefferson Headache Center, Thomas Jefferson University, Philadelphia, PA; ²Mayo Clinic, Phoenix, AZ; ³Teva Pharmaceuticals, Frazer, PA. (Control ID #3185629)

BACKGROUND: Migraine is a highly prevalent neurological disorder and one of the leading causes of years lived with disability worldwide. Chronic migraine (CM) is defined by having 15 or more headache days per month, at least 8 of which are migraine days. Patients with episodic migraine (EM) have fewer than 15 headache days per month. Preventive migraine treatment is recommended in patients with 4 or more headache days per month with some impairment. Fremanezumab is a fully humanized monoclonal antibody (IgG2 a) that selectively targets calcitonin gene-related peptide (CGRP), a neuropeptide involved in the pathophysiology of migraine. Fremanezumab is approved for the preventive treatment of migraine in adults. The HALO trials assessed the efficacy and safety of fremanezumab for the preventive treatment of CM and EM.

METHODS: HALO CM and HALO EM were concurrent, multicenter, randomized, double-blind, placebo-controlled, parallel-group Phase 3 studies evaluating the efficacy and safety of fremanezumab for the preventive treatment of CM and EM. Adults with CM or EM, confirmed during a 28-day pre-treatment period, were randomized to receive subcutaneous fremanezumab quarterly (675 mg at baseline and placebo at Weeks 4 and 8), fremanezumab monthly (CM: 675 mg at baseline, and 225 mg at Weeks 4 and 8; EM: 225 mg at baseline and Weeks 4 and 8), or matching placebo over a 12-week period. The primary endpoint for HALO CM was the mean change in the average number of headache days of at least moderate severity: a day in which headache pain lasted 4 consecutive hours and had a peak severity of at least a moderate level, or an acute migraine-specific medication (triptans or ergots) was used to treat a headache of any severity or duration. The HALO EM primary endpoint was the mean change from baseline in the monthly average number of migraine days: a day with 2 consecutive hours of a headache meeting criteria for migraine, probable migraine, or when acute migraine-specific medication (triptans or ergots) was used to treat a headache.

RESULTS: In HALO CM, 1130 patients were randomized to fremanezumab quarterly (n=376), fremanezumab monthly (n=379), or placebo (n=375), and 1034 patients (92%) completed the study. In HALO EM, 875 patients were randomized to fremanezumab quarterly (n=291), fremanezumab monthly (n=290), or placebo (n=294), and 791 patients (90%) completed the study. On average, CM and EM patients were approximately 41 years of age, with 20 years since migraine diagnosis. Both CM and EM patients were highly disabled based on six-item Headache

Impact Test (HIT-6) scores and Migraine Disability Assessment (MIDAS) scores.

CONCLUSIONS: The HALO trials were designed to provide flexible dosing options to establish the efficacy and safety of fremanezumab for the preventive treatment of migraine. The study population was representative of the real-world clinical patient population.

OXYCODONE URINE DRUG TESTS IDENTIFY POTENTIAL MISUSE AND DIVERSION AMONG PATIENTS PRESCRIBED OPIOIDS FOR CHRONIC PAIN

Marc Larochelle¹; Ricardo Cruz²; Sarah Kosakowski²; Douglas Gourlay³; Daniel P. Alford¹; Ziming Xuan⁴; Erin E. Krebs⁵; Karen E. Lasser²; Jeffrey H. Samet⁶; Jane M. Liebschutz⁷. ¹Boston University School of Medicine and Boston Medical Center, Boston, MA; ²Boston Medical Center, Boston, MA; ³Wasser Pain Management Centre, Toronto, ON, Canada; ⁴Boston University School of Public Health, Boston, MA; ⁵Minneapolis VA Health Care System, Minneapolis, MN; ⁶Boston University School of Medicine, Boston, MA; ⁷University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #3185832)

BACKGROUND: Guidelines recommend urine drug testing (UDT) as one component of a risk monitoring strategy for patients prescribed opioids for chronic pain. Few studies have examined whether UDT results are associated with substance misuse or diversion.

METHODS: A retrospective cohort study using data from TOPCARE, a trial to promote guideline-concordant care for chronic pain patients prescribed opioids in four Boston, MA primary care clinics. The multimodal intervention included a nurse care manager who assisted physicians with UDT collection and interpretation. We included 2,111 oxycodone urine immunoassays collected over one year for 611 patients of primary care physicians randomized to the intervention. We reviewed all assays and identified 490 (23.2%) with a result discordant from oxycodone prescription status (i.e., oxycodone negative during oxycodone prescription or oxycodone positive without active oxycodone prescription). For these 490, we abstracted detailed clinical data from the EMR, including UDT collection and interpretation notes from the intervention nurse care manager. Two addiction medicine experts adjudicated each oxycodone assay as follows: expected; equivocal (discordant assay without EMR evidence of misuse/diversion); or unexpected (discordant assay with EMR evidence of misuse/ diversion). We reconciled adjudication differences via discussion, and further categorized each patient as: expected (all expected), equivocal, or unexpected (> 1 unexpected).

RESULTS: Overall, we adjudicated 79.1% of the 2,111 oxycodone assays as expected, 7.3% equivocal, and 13.6% unexpected (Table). Of the 490 assays initially screened as having a result discordant from oxycodone prescription status, 58.8% were found to have EMR evidence of misuse or diversion and adjudicated as unexpected, 31.2% were adjudicated as equivocal, and 10.0% expected. For 406 (65.0%) patients, all oxycodone assays were adjudicated as expected, and 127 patients (20.3%) had at least one unexpected oxycodone assay.

CONCLUSIONS: An oxycodone urine immunoassay result discordant from prescription status offers clinical utility for identifying potential misuse or diversion. The urine test should be followed up with clinical assessment. Whether routine UDT improves patient outcomes remains unknown.

PAIN AGREEMENTS: TIME-TO-EVENT ANALYSIS OF SUBSTANCE MISUSE IN A PRIMARY CARE CHRONIC PAIN PROGRAM

Paul Chelminski¹; Timothy Ives¹; Ameer Ghodke²; Anna Austin⁴; Naishal Patel³; Will Bennett¹; Sharon Eshet¹. ¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²University of North Carolina, Cary, NC; ³UNC-Chapel Hill, Cary, NC; ⁴UNC Chapel Hill School of Public Health, Chapel Hill, NC. (Control ID #3171392)

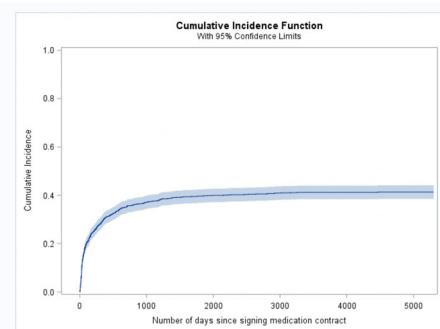

BACKGROUND: Medication agreements (MA) are used to specify conditions for opioid use in chronic pain patients. MAs codify universal opioid prescribing precautions including urine toxicological testing (UTS), and describe treatment objectives, side effects, and responsibilities of the patient and provider. Violations of MAs include UTS positive for illicit or non-prescribed controlled substances, prescription alteration/forgery, doctor-shopping, and diversion. To date, the time course of when a violation occurs after signing a MA is unknown. The aim of this study was to provide a time-to-event analysis of MA violations over a 15-year period within an academic internal medicine clinic.

METHODS: The University of North Carolina General Medicine Pain Service (GMPS) manages opioid-treated patients referred by their PCPs within an internal medicine clinic. All patients sign MAs. We performed a time-to-event analysis of MA violations from 2002 to 2017, treating discontinuation of care as a competing event, and examined demographic correlates.

RESULTS: We enrolled 937 patients in the GMPS from 2002 to 2017. The average age was 51; 58% were female; 69% were white. A total of 40.3% of patients had one or more violations during GMPS enrollment. Almost one-half of violations were due to inconsistent use of controlled substances. Thirty percent of patients had a violation within 365 days of signing the MA, and 20% had a violation within 90 days (Figure). Ten percent occurred after a year. Within 365 days of signing the MA, the incidence of violations was significantly higher among men compared to women (38% vs. 22%), current compared to never or former smokers (41% vs. 21%), and in patients with a DUI or drug-related offense prior to or after the violation (52% vs. 28%).

CONCLUSIONS: MA violations are common in opioid-treated patients with chronic pain. A majority of violations are seen within three months of signing, but a substantial number of violations were detected at a year and farther out. Proxies for substance use disorders predicted an increased risk for violations. Given the individual and societal risks of opioid use disorders, MAs are valuable clinical tools whose application should not be relaxed over time.

Figure 1. Cumulative incidence function of time to first medication contract violation among pain service patients, 2002-2017 (N=1,210). Calculated using nonparametric estimators and assuming discontinuation of care at the pain and a competing risk and death as a censoring event.

PAJAMA TIME: WORKING AFTER WORK IN THE ELECTRONIC HEALTH RECORD

Kanan Shah¹; Harry S. Saag^{2, 1}; Leora I. Horwitz^{2, 1}; Paul Testa³. ¹NYU Langone School of Medicine, Gibsonville, NC; ²NYU School of Medicine, New York, NY; ³NYU Langone Health, New York, NY. (Control ID #3182665)

BACKGROUND: Electronic health record (EHR) documentation may contribute to burnout, especially for those with substantial clinical effort. We assessed whether clinical effort is associated with working in the EHR after work hours.

METHODS: We included all ambulatory physicians in a medicine specialty continuously practicing at any NYU Langone Health Faculty Group Practice site between May 1 and October 31, 2018. We quantified minutes logged into the EHR on days without scheduled appointments, and minutes logged into the EHR 30 minutes before and after appointments on days with scheduled appointments. We termed this time "work after work." We categorized physicians by their average number of days with appointments per week. Data were analyzed using SAS 9.4 (SAS Institute, Cary, NC). We calculated least squares means of fixed effects to account for heterogeneous variances, and compared means using Tukey's multiple comparison test. This study met institutional review board criteria for quality improvement work.

RESULTS: We included 300 physicians, of whom 28.6% were general internists. The average physician had 3 days/week with scheduled appointments, spent 114.9 min in the EHR on days without appointments, and spent 21.7 min in the EHR after work hours on days with appointments. Time spent in the EHR on days without appointments increased with the number of appointment days per week (14.7 min/unscheduled day for 1 day/week vs. 193.8 min/unscheduled day for >4 days/week, p<0.001). Time spent in the EHR after hours on days with scheduled appointments did not significantly differ (Table 1).

CONCLUSIONS: All ambulatory physicians spend a substantial amount of time working in the EHR after hours and on unscheduled days (including weekends), but physicians with more clinical time were disproportionately burdened. The most clinically active spent an average of 2.8 hours in the EHR each unscheduled day. These findings add to concerns about EHR usability and documentation burden, particularly for busier clinicians. Our institution is now building dashboards to track work after work, offloading tasks to ancillary team members to reduce physician work burden, and exploring whether outliers would benefit from personalized technical assistance and training. Work after work analyses could be employed elsewhere to motivate similar improvements.

Time spent on work after work, by clinical effort

| Days per week with appointments | Average work after work (min/day) on days with appointments, minutes | Average work (min/day) on days without appointments, minutes |
|---------------------------------|--|--|
| (0-1] (n=7) | 28.9 ± 11.7 | 14.7 ± 3.6 |
| (1-2] (n=17) | 12.8 ± 5.5 | 37.3 ± 7.8 |
| (2-3] (n=59) | 20.6 ± 3.3 | 58.9 ± 7.2 |
| (3-4] (n=113) | 20.3 ± 2.2 | 90.0 ± 10.5 |
| (4-5] (n=104) | 24.5 ± 2.7 | 193.8 ± 39.8 |
| | p=0.34 | p<0.001 |

PARTNERING WITH ADVOCATES TO ASSESS BREAST DENSITY PATIENT EDUCATIONAL MATERIALS

Christine Gunn^{1, 2}; Mark Kennedy³; Ariel Maschke¹; Michael D. Fishman⁴; Margaret Hopkins⁵; Erica T. Warner⁵. ¹Boston University, Boston, MA; ²Boston University School of Public Health, Boston, MA; ³Boston Public Health Commission, Boston, MA; ⁴Boston Medical Center, Boston, MA; ⁵Massachusetts General Hospital, Boston, MA. (Control ID #3184896)

BACKGROUND: Mammographic breast density increases lifetime risk of breast cancer and reduces mammography sensitivity. Thus, 34 states enacted laws that require women be informed for their breast density. Evidence shows that relative to White women, Black women are more likely to have dense breast tissue, yet experience more anxiety and have less knowledge about their density. This is in part due to discordance between population health literacy levels and the grade levels at which breast density notifications are written. This study aims to 1) identify preferred educational content, format and opportunities for cultural tailoring and 2) characterize the readability and understandability of breast density information to improve the quality of breast density education for Black women.

METHODS: Members of the Pink & Black Education and Support Network, a group of Black breast cancer patients/survivors in Boston, were invited to discuss breast density materials. We used a cognitive priming task in which women distributed 10 dots across six elements of communication, indicating the relative importance of each. Ratings guided the discussion of two sample materials from national breast cancer advocacy groups. We also compiled 21 publicly-available educational materials designed for women with dense breasts. Readability was evaluated using the Flesch-Kincaid and Dale-Chall New Readability metrics. Understandability was measured using the Patient Education Material Assessment Tool (PEMAT), where higher scores suggest patients will be able to understand and act on the information provided. Scores were rated by two coders and discrepancies resolved in a 3-person consensus process.

RESULTS: Nine Pink & Black members convened over 3 sessions. The cognitive priming task revealed that the most important elements of breast density education were "knowing what I can do about dense breasts", "being able to ask questions", and "getting information quickly". Consistent with readability analyses, women suggested current materials did not adequately convey a clear definition of breast density, but rather used complex medical jargon instead of simple language. Women advised briefing women in waiting rooms prior to their mammogram about breast density using informational videos. To decrease anxiety, women desired information via peers or health navigators, rather than a doctor. The mean Flesh-Kincaid grade for the 21 breast density materials was 9.7 (5.5 - 12.7). Thirteen were assessed at Grade 11-12 on the New Dale-Chall score, one Grade 10-11, and six Grade 9-10. The average PEMAT score was 66/100 (40-81).

CONCLUSIONS: We found that breast density education materials available to the public exceed the recommended reading level of 5-8th grade for health education materials, creating a barrier for patients' ability to use this information for breast cancer screening decision-making. Educational materials that respond to women's preferences are in development and will be presented to complement these analyses.

PATIENT AND PROVIDER PERCEPTIONS OF DIABETES GROUP VISITS AT COMMUNITY HEALTH CENTERS

Samantha Mannion¹; Erin M. Staab¹; Sandra Ham¹; Amanda Campbell³; Cynthia T. Schaefer²; Michael T. Quinn¹; Arshiya A. Baig¹. ¹University of Chicago, Chicago, IL; ²University of Evansville, Evansville, IN; ³Midwest Clinicians' Network, East Lansing, MI. (Control ID #3175222)

BACKGROUND: A pilot study in the Midwest with 6 community health centers (CHCs) defined diabetes group visits as shared medical appointments that include diabetes education in a group setting and individual visits with a medical provider. Providers and staff were given training and curriculum prior to implementing diabetes group visits at their health centers. This study analyzes patient and provider satisfaction with group visits, which is integral to their long-term viability and success.

METHODS: Adult patients at Midwestern health centers with an A1c of at least 8% were invited to participate in a 6-month group visit intervention. Surveys were administered to patients at baseline and at 6 months. Providers (primary care physicians, other clinicians, and non-clinical staff) were surveyed about the implementation of group visits 6 months after the first training session. Descriptive statistics were computed for survey responses using Excel. Eighteen semi-structured one-on-one interviews were conducted with providers 5-6 months and 9-10 months after the initial training session and coded for themes using HyperResearch.

RESULTS: Six CHCs had 27 total providers; 18 completed the 6 month survey. Of the 51 patients enrolled, 31 completed the 6-month survey. Ninety percent of patients reported "a lot" of overall satisfaction with group visits. Half (53%) of patients felt "a lot" of support from other patients in the group and another 30% felt "some" support. Three-quarters (77%) of patients agreed that they liked having a longer visit "a lot." Providers and staff felt that group visits improved team dynamics by boosting staff morale (89%) and fostering interdisciplinary collaboration (94%). In interviews, providers felt that patients benefitted from interacting with the group and that they received more education and attention in a longer visit, especially a visit intended to focus solely on diabetes. Providers felt that implementation of group visits improved community relations for the health center. Only 39% of providers felt provider productivity had improved. Time was cited as the biggest challenge to implementation; this was commonly attributed to the initial time investment for a new program and to study-specific tasks such as chart abstraction.

CONCLUSIONS: Patients and providers participating in a diabetes group visit pilot program reported high satisfaction with the intervention. Patients benefited from interacting with other participants who shared their condition, and they enjoyed the increased education and attention they received in a longer group visit. Providers were excited to implement group visits as a way to better serve their patients and lead the way in healthcare innovation. Providers expressed a desire to continue group visits after the pilot program was finished and to expand them to other medical conditions. Other CHCs contemplating group visits should consider the up-front time commitment needed to organize group visits for the first time.

PATIENT CENTERED MEDICAL HOME IMPLEMENTATION AND CHRONIC DISEASE CARE QUALITY IN PATIENTS WITH MULTIMORBIDITY

Linnaea C. Schuttner^{1,2}; Edwin Wong^{1,2}; Ann-Marie Rosland^{3,4}; Karin M. Nelson^{1,2}; Ashok Reddy^{1,2}. ¹VA Puget Sound Healthcare System, Seattle, WA; ²University of Washington, Seattle, WA; ³VA Pittsburgh, Pittsburgh, PA; ⁴University of Pittsburgh School of Medicine, Pittsburgh, PA. (Control ID #3165031)

BACKGROUND: Improving chronic disease management is central to the patient-centered medical home (PCMH) and has been a demonstrated benefit of high-performing PCMH clinics. However, impacts on patients living with multimorbidity (3 or more diseases in 3 or more body systems)

are less established. Thus, we examined the association between PCMH implementation and quality of care in multimorbid patients within an integrated health system.

METHODS: We conducted a retrospective cohort study among a sample of multimorbid adult patients (N = 318,764) seen in a Veterans Affairs (VA) primary care clinic in 2012. We measured PCMH implementation in 2012 with the validated Patient Aligned Care Team Implementation Progress Index (PI²). Higher PI² scores indicate better performance on eight domains: access; continuity; care coordination; comprehensiveness; self-management support; patient-centered care; shared decision-making; and team-based care. Primary outcomes were binary patient-level measures of 16 quality metrics, including lipid, blood pressure, and glycemic control, medication adherence, and preventative care, 18 to 24 months after receiving care in a PCMH. We used generalized estimating equations to compare proportions of patients meeting the metric across clinics categorized by PI² quintile, adjusting for patient and clinic characteristics, and ANOVA for tests of trend.

RESULTS: The cohort was mostly male (96%) with an average age of 64.8 years and 5.1 chronic diagnoses. Receipt of care at clinics with higher PCMH implementation was associated with progressive odds of meeting the quality metric for 7 of 16 outcomes: diabetic patients with glycemic (P<0.0001 for test of trend across PI² quintiles of clinics) and lipid control (P=0.04); screening (P<0.005) and timely follow-up of positive screens (P=0.02) for PTSD; ischemic heart disease patients with lipid control (P<0.01); and influenza (P=0.02) and pneumococcal (P<0.005) vaccination in older patients. No care differences were found for the remaining 9 metrics (diabetics with annual foot exam or blood pressure control, depression or alcohol screening or follow-up, heart failure patients on appropriate medications, hypertensive patients with blood pressure control, or influenza vaccines in non-elderly patients).

CONCLUSIONS: We found multimorbid patients receiving primary care at VA clinics with greater PCMH implementation received better clinical care across 7 of 16 quality markers, in particular adherence-related metrics (lipids, glycemic control), PTSD-related care, and vaccine rates in older patients. Care related to distinct tasks - such as a diabetic foot exam, may be less impacted by the level of PCMH implementation. Our findings are among the first to associate greater PCMH implementation with higher quality of chronic disease care for multimorbid adults within an integrated health system.

PATIENT CONCENTRATION AMONG NURSING HOME PHYSICIANS AND POST-ACUTE CARE OUTCOMES

Kira Ryskina¹; Rachel M. Werner². ¹University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania and Philadelphia VA, Philadelphia, PA. (Control ID #3185285)

BACKGROUND: Post-acute care in nursing homes (NHs), is common, costly and variable in quality. More and more generalist physicians are specializing in providing NH care, but whether these physicians care for a majority of patients in one or two facilities vs. a small proportion of patients in multiple facilities is unknown. Our objective was to measure the association between the degree to which NHs concentrate their patient care among a few versus many physicians who specialize in NH practice and patient outcomes.

METHODS: We analyzed 2,731,351 discharges by Medicare fee-for-service beneficiaries over 66 years of age from acute care hospitals to 15,013 NHs between 2012 and 2014. Physicians in generalist specialties with at least 90% of claims for NH care were considered NH specialists. Patients were assigned to the NH attending physician based on plurality of claims. The degree to which NHs concentrate care of their patients among a few or many physicians was measured by calculating a facility-level Herfindahl-Hirschman Index (HHI) as the weighted sum of each attending physician's share of the NH's patient population. We estimated the

independent and joint effects of NH physician specialization and concentration on three outcomes: 30-day rehospitalization, 60-day episode Medicare payments (both derived from claims), and successful discharge to community (derived from the NH Minimum Data Set). To measure 60-day episode of care payments we summed all facility and professional payments by Medicare Parts A and B (including hospital, NH, physician and other provider payments). Successful discharge to community was identified when a patient was discharged to the community within 100 days of admission to NH and remained alive and not readmitted to a hospital or NH for at least 30 days. All outcomes were adjusted for demographics (age, sex, race) and 72 clinical variables used by CMS for clinical measure risk-adjustment. To account for heterogeneity across facilities, we included NH fixed effects. Outcomes were modeled using linear regression. Confidence intervals were adjusted for clustering within NHs.

RESULTS: The median HHI across U.S. nursing homes was 0.29 (IQR 0.19-0.44). Controlling for the degree of patient concentration among few vs. many physicians, patients under the care of physicians who specialized in NH care were less likely to be rehospitalized after 30-days (14.54% vs. 15.92%; adjusted difference, -1.38%, 95% CI -1.77 to -1.00), more likely to be successfully discharged to the community (59.95% vs. 59.09%; adjusted difference, 0.86%, 95% CI 0.40 to 1.33), but had higher 60-day Medicare costs (\$31,150 vs. \$30,875; adjusted difference, \$275; 95% CI \$113 to \$437). These differences were consistent across different levels of patient-physician concentration.

CONCLUSIONS: NHs whose patients are treated by generalist physicians who specialize in NH practice may achieve marginally better patient outcomes at slightly higher costs.

PATIENT DECISION-MAKING ABOUT USE OF HEALTH SAVINGS ACCOUNTS

Jeffrey T. Kullgren^{1, 2}; Elizabeth Q. Cliff²; Christopher Krenz²; Helen Levy^{2, 2}; Brady T. West²; A. M. Fendrick^{2, 2}; Angie Fagerlin^{3, 4}. ¹VA Ann Arbor Healthcare System, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³University of Utah, Salt Lake City, UT; ⁴Salt Lake City VA Medical Center, Salt Lake City, UT. (Control ID #3184967)

BACKGROUND: Expansion of health savings accounts (HSAs) has been a centerpiece of recent federal health reform proposals. These accounts can be used by patients who are enrolled in a high-deductible health plan (HDHP) to save tax-free for health care expenses, with the policy goals of lessening patients' health care cost burdens and helping them be more discerning health care consumers. Despite the popularity of HSAs among many policymakers, little is known about which HDHP enrollees are more likely to have an HSA, what factors are associated with higher levels of saving in HSAs, and why patients with HSAs forego opportunities to contribute to their accounts.

METHODS: We surveyed 1,637 GfK KnowledgePanel participants who were 18 years of age and older and had been enrolled in an HDHP for at least a year (response rate 55%). Respondents indicated whether they had an HSA and, if so, how much they had saved for health care in the past year. Individuals who had not saved for health care were asked why not. We used multivariable logistic regression to identify factors associated with having an HSA. Among individuals with an HSA, we identified the most frequent levels of saving for health care expenses and used multivariable ordered logistic regression to identify factors associated with higher levels of saving. Among individuals who had an HSA but had not contributed to their account, we identified the most frequent reasons why. All analyses used survey weights to generate nationally representative estimates.

RESULTS: Most individuals (58%) reported having an HSA. Factors associated with having an HSA included having a graduate degree, no chronic conditions, and higher levels of financial literacy and health insurance literacy. Among individuals with an HSA, the most frequent levels of saving for health care expenses were \$0 (44%), \$2,000 or more (22%), and \$500 to \$999 (10%). Factors associated with higher levels of saving in HSAs included older age, more education, and higher health insurance

literacy. Among individuals who had an HSA but had not contributed to their account, the most common reasons were not needing health care services (45%), already having enough savings to pay for health care (40%), and not having considered saving for health care (36%).

CONCLUSIONS: While most Americans enrolled in an HDHP have an HSA, nearly half of those with an HSA have not used their account to save for any health care expenses. Individuals with less education and lower health insurance literacy are less likely to have an HSA and, even when they do, to contribute to it. Federal efforts to expand HSAs may not achieve their policy goals of lessening patients' health care cost burdens and helping them be more discerning health care consumers without concurrent efforts to increase health insurance literacy and facilitate use of HSAs among individuals who are less likely to take up and contribute to these accounts.

PATIENT EXPERIENCE IN A CLINIC-LEVEL BEHAVIORAL ECONOMIC INTERVENTION TO REDUCE OVERUSE OF LOW-VALUE TREATMENTS FOR CHRONIC CONDITIONS AMONG OLDER ADULTS

Jeffrey T. Kullgren^{1, 2}; Megan Slowey³; Hyungjin M. Kim^{2, 1}; Joseph T. Colbert²; Kerry A. Ryan²; Angie Fagerlin^{4, 5}; Barbara Soyster²; Stuart Winston⁶; Jane Forman¹; Eve A. Kerr^{1, 2}. ¹VA Ann Arbor Healthcare System, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³Center for Health and Research Transformation, Ann Arbor, MI; ⁴University of Utah, Salt Lake City, UT; ⁵Salt Lake City VA Medical Center, Salt Lake City, UT; ⁶IHA, Ann Arbor, MI. (Control ID #3184996)

BACKGROUND: The *Choosing Wisely*® campaign recommends that older patients avoid use of low-value care such as hypoglycemic diabetes medications to achieve a hemoglobin A1c < 7.5% and use of benzodiazepines and sedative-hypnotics for insomnia or anxiety. Yet, use of these low-value treatments is common, and it is unclear how to engage older patients and their providers to avoid such overuse while maintaining strong patient-provider relationships.

METHODS: We conducted an 8-month intervention in 8 primary care clinics from 2 health systems. Intervention clinic primary care providers (PCPs) were shown *Choosing Wisely* recommendations to avoid overtreatment of diabetes, insomnia, and anxiety among adults age 65 and older, and invited to commit their future selves (i.e., precommit) to following these recommendations by signing a commitment document. To provide a social incentive, precommitted PCPs had their photos displayed on clinic posters. Precommitted PCPs also received weekly emails with resources to help them and their patients avoid low-value treatments, and had access to point-of-care patient education handouts about overuse that were mailed to applicable patients prior to scheduled primary care visits. After primary care visits, we surveyed 354 older patients with diabetes, insomnia, or anxiety: 167 from the 8 intervention clinics and 187 from 7 control primary care clinics. Surveys asked patients whether at their visit they talked with their PCP about medications for their condition and, if so, changed their medications, and about their rating of and trust in their PCP. We used multilevel modeling to estimate differences in these outcomes between intervention and control clinic patients while accounting for PCP-level correlation.

RESULTS: Intervention clinic patients with diabetes were no more likely than control clinic patients with diabetes to have discussed their diabetes medications with their PCP, but conditional on discussing diabetes medications were more likely to report taking less diabetes medication after their PCP visit (13.5% vs. 1.0%; $P = 0.01$). Intervention clinic patients with insomnia or anxiety were no more likely to report discussing or changing their medications for these conditions. There were no differences between intervention and control clinic patients in ratings of, or trust in, their PCPs.

CONCLUSIONS: A behavioral economic intervention that sought to engage PCPs and older patients to avoid use of low-value treatments for chronic conditions may have reduced use of medications for diabetes, but not for insomnia or anxiety, and did not adversely affect patients' ratings of, or trust in, their PCPs. These results suggest behavioral economic interventions can reduce overuse of low-value treatments for chronic conditions like diabetes

without negatively affecting patient-provider relationships, but may need to be coupled with other approaches to reduce use of low-value treatments for more symptomatic conditions like insomnia and anxiety.

PATIENT NAVIGATION AMONG RECENTLY HOSPITALIZED SMOKERS TO PROMOTE SMOKING CESSATION: BASELINE RESULTS FROM A PILOT RANDOMIZED CONTROLLED TRIAL

Lisa M. Quintiliani^{1,2}; Ve Truong²; Jennifer Murillo²; Hasmeena Kathuria^{1,2}; Belinda Borrelli³; Karen E. Lasser^{1,2}. ¹Boston University, Boston, MA; ²Boston Medical Center, Boston, MA; ³Boston University Henry M. Goldman School of Dental Medicine, Boston, MA. (Control ID #3176007)

BACKGROUND: Tobacco treatment interventions initiated during hospitalizations with supportive contacts after discharge promote continuity of treatment and enhance likelihood of cessation. However, to our knowledge, these interventions lack screening for and addressing health-related social needs. Such screening may improve intervention effectiveness: if social needs are addressed, patients may be better able to focus on cessation. Our objective is to present baseline and process data from a pilot study examining the feasibility of a tobacco treatment intervention that includes screening for health-related social needs among recently hospitalized smokers at a large-safety net hospital.

METHODS: In a two-group 3-month pilot randomized controlled trial, we assigned hospitalized smokers to either a control group (list of smoking cessation resources) or an intervention group (up to 10 hours of patient navigation over a 3-month period, in which a navigator screens for health-related social needs and discusses smoking with the patient and links patients to effective treatments and resources). Inclusion criteria were: 18 years old, hospitalized at the time of randomization, smoked 1 cigarette/day, had plans to ever quit smoking, spoke English, and owned a telephone. We assessed socio-demographics, smoking-related variables, and process data.

RESULTS: Of 38 individuals screened and found eligible, 36 (95%) were enrolled. Participants (n=36, mean age=53.9 years, 61.1% Hispanic, 66.6% high school education or less, 80.5% Medicaid) smoked a mean of 12.2 cigarettes/day. Initially, our intervention protocol was to provide 2 hours of navigation over 1 month. However, only 3 of 7 participants received a minimum intervention dose (completion of the social needs screener and at least one conversation about smoking), as the navigator was unable to contact 1 participant and 3 participants were too sick (as reported by the patient or perceived by the navigator). Because so few participants received the minimum dose, we changed our protocol (allowing up to 10 hours of navigation over 3 months). Among those (n=6) who have completed the 3-month intervention, 3 participants received the minimum intervention dose. The number of contacts per participant ranged from 9-16; contacts included texting, telephone, and home visits. Among the six participants who were screened for health-related social needs, all reported lack of employment, 2 reported trouble paying heating bills, and 1 reported not having a high school degree; 1 person requested follow-up services after completing the screener.

CONCLUSIONS: While study enrollment was high among eligible patients, the feasibility of this intervention is limited by difficulty contacting recently hospitalized patients post-discharge due to illness. Future iterations of this intervention could introduce the navigator to the patient while the patient is still hospitalized. Future research should explore the acceptability of screening patients for health-related social needs.

PATIENT OPINIONS ABOUT DIGITAL MESSAGING FOR CLINICAL RESEARCH RECRUITMENT

Michael Cantor^{2,1}; Michael Mishik³. ¹NYU School of Medicine, New York, NY; ²Regeneron Pharmaceuticals, Tarrytown, NY; ³NYU Langone Health, New York, NY. (Control ID #3142707)

BACKGROUND: Identifying and recruiting patients for clinical research remain major challenges for researchers. EHRs are playing larger roles in recruitment, from helping identify cohorts to alerting clinicians about potentially eligible patients. One major issue around using EHRs for recruitment is

understanding the best way to manage the amount and type of messaging patients receive. Because research-related communications is a relatively new area, few institutions have set policies in this area. Before setting policy at NYU Langone Health, we chose to survey our patient population to better gauge their beliefs and to obtain data that would help us formulate a policy that aligns with patients' actual preferences rather than their hypothetical concerns.

METHODS: The NYU School of Medicine IRB determined that this project was exempt from review. We developed a 10-question survey in our institution's RedCap system. The survey was developed with input from our institutional Research Governance Group, who gave input on both content and wording of the questions. We then obtained a random sample of 20,000 adult, active MyChart (our Epic® patient portal) users, and sent a survey invitation to 10,000 patients per week for two weeks. The survey was completely anonymous, and the invitation contained a direct link to the RedCap survey. We closed the survey after 3 weeks.

RESULTS: We received 2157 responses to the survey. 61.7% of respondents were female, 83% were white, and 11% identified as Hispanic/Latino. 2/3 of patients were within the 46-75 age range. 72% of patients responded that they would be interested in participating in research studies, and 87% of all patients responded that they would be interested in receiving research-related messages. Responses about limits on the number of messages that patients receive were nearly evenly split, with 46% responding that there should not be a limit on the number of research-related messages received, and 39% responding that there should be a limit. Over 90% wanted the option to opt-out of receiving further messages with each invitation. Opinion about the "right" number of research-related messages that a patient could receive in a particular time period was mixed, but were nearly evenly split between 1-2 times a month and no limit on messages.

CONCLUSIONS: Developing and distributing the survey through the patient portal was a relatively straightforward process and was relatively quick to implement after institutional approval. Our survey revealed engaged patients who are interested in finding out more about research, and who wish to have input into and control over the number and types of research-related messages they receive. Performing a similar survey in a larger, more diverse population would help give a more accurate picture of broader patient preferences. Digital messaging can be an effective tool for research-related communications, and could be added to the current toolbox of general recruitment techniques.

PATIENT STAKEHOLDER ENGAGEMENT IN RESEARCH: A SYSTEMATIC REVIEW TO DESCRIBE FOUNDATION PRINCIPLES AND BEST PRACTICE ACTIVITIES

James D. Harrison¹; Andrew Auerbach¹; Krista Woodward⁴; Wendy Anderson⁵; Maureen Fagan³; Martha Carmie²; Catherine Hanson³; Jim Banta⁶; Gina Symczak⁶; Edmondo Robinson⁸; Jeffrey Schnipper⁷; Celene Wong²; Rachel Weiss¹. ¹University of California San Francisco, San Francisco, CA; ²Brigham and Women's Hospital, Milton, MA; ³University of Miami Health System, Miami, FL; ⁴Patient Centered Outcomes Research Institute, Washington DC, DC; ⁵Division of Palliative Medicine, University of California San Francisco, San Francisco, CA; ⁶Intensive Care Unit Patient & Family Advisory Council, University of California San Francisco, San Francisco, CA; ⁷Department of Medicine, Brigham & Women's Hospital, Boston, MA; ⁸Christina Care Health System, Delaware, DE. (Control ID #3162491)

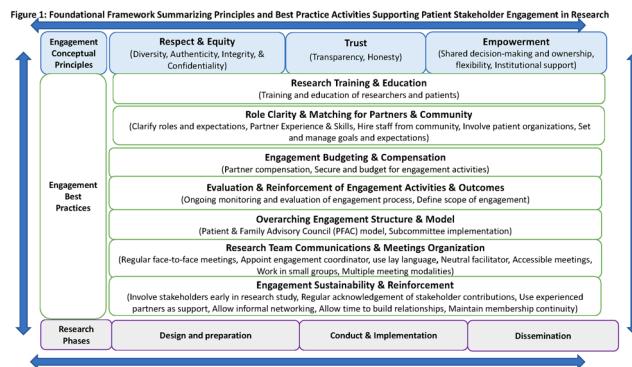

BACKGROUND: Health research is evolving to include patient stakeholders (patients, families and caregivers) as active members of research teams. The proliferation of frameworks describing the conceptual foundations underlying this engagement, and strategies detailing best practice activities to support this process has led to a diffusion of information. Therefore, the aims of this study are to identify, quantify and summarize 1) the foundational principles of patient stakeholder engagement in research and 2) best practice activities to support these efforts.

METHODS: We conducted a systematic review of the literature supplemented with review of the gray literature to create a narrative review. We accessed a publicly available repository of systematically identified literature of English-

language articles from PubMed/MEDLINE related to patient stakeholder engagement in research. Two reviewers independently screened articles to determine their relevance. The contents of relevant articles were then reviewed, and data abstracted - specifically domains that were reported as foundational principles of patient stakeholder engagement in research and best activities that support the operationalization of engagement.

RESULTS: We identified 990 potentially relevant articles and reports of which 935 (94.4%) were excluded and 55 (5.5%) deemed relevant. Fifteen foundational principles and 25 best practice activities were identified. The most commonly reported foundational principles were "respect" (n=25, 45%) and "equitable power between all team members" (n=21, 38%). Creating "trust between patient stakeholders and researchers" was described in 17 (31%) articles. Twenty-seven (49%) articles emphasized the best practice of providing training and education for both patient stakeholder and researchers. Providing financial compensation for patient stakeholders' time and expertise was noted in 19 (35%) articles. Nineteen articles (35%) emphasized regular, bidirectional dialogue between patient partners and researchers as important for successful engagement. An overarching foundational framework summarizing key findings is shown in Figure 1.

CONCLUSIONS: Engaging patient stakeholders in research as partners presents an opportunity to design, implement and disseminate patient centered research. Our review creates an overarching foundational framework to facilitate authentic and sustainable partnerships between patient stakeholders and researchers.

PATIENT-CENTEREDNESS OF THE MEDICATION RECONCILIATION PROCESS IN THE VA PRIMARY CARE SETTING

Robin S. Mickelson²; Jea Young Min²; Susan Byerly²; Amanda S. Mixon¹. ¹VA Tennessee Valley Healthcare System and Vanderbilt University, Nashville, TN; ²Department of Veterans Affairs, Nashville, Monteagle, TN. (Control ID #3143013)

BACKGROUND: High quality medication reconciliation (MR) is critical to prevent medication errors. Inpatient MR toolkits have been developed, tested, and are efficacious; however, less is understood about the current outpatient MR process particularly the degree of patient-centeredness and patient engagement.

METHODS: We conducted an observational descriptive study from April to June 2018, in which we recruited 30 Veterans with non-urgent appointments and a medication list in their medical record from VA primary care clinics. We observed the primary care team conduct MR and assessed patient-centeredness, whether it (1) created a shared understanding; (2) explored the biopsychosocial context; (3) provided patient-friendly explanations; (4) encouraged active participation; (5) uncovered the patient's perspective; (6) produced decisions based on evidence, values, and feasibility; and, (7) created trust. We assessed patient-level subjective numeracy, health engagement, and interpersonal processes of care using validated measures. We conducted semi-structured interviews to evaluate patients' engagement in as well as barriers and facilitators to the MR process. Interviews were transcribed and imported into NVivo® software with the observation notes. Two researchers utilized the aspects of patient engagement and patient-centeredness to identify categories and

sub-categories through directed content analysis.

RESULTS: The patients' median age was 70, 20% African American, 7% female. Patients had an average of 13.5 medications on their list. The mean subjective numeracy was high (5.3 on 1 to 6 scale), the mean perceived processes of care around medications was excellent (1.2 on 1 to 5 scale), and the mean engagement in health was high (6 on 0 to 7 scale). With regard to patient-centeredness and patient engagement, qualitative analyses revealed a MR process constrained by deficits in 3 areas: shared understanding, a standardized process, and tools to facilitate adequate information exchange. Patients misunderstand the purpose of the MR process, their role, and often had different goals regarding medications. Healthcare providers (HCP) did not always ask about adherence, explore biopsychosocial barriers and supports, or assess the patient's beliefs or understanding. During the medication review, generic names often confuse patients, although most providers used patient-friendly explanations to help patients understand the mechanism of action and side effects. Familiarity with the HCP, trust, and a friendly, unhurried attitude facilitated active patient participation in the conversation.

CONCLUSIONS: The outpatient MR process varied widely in its degree of patient-centeredness; therefore, opportunities to improve the patient's experience and efficiency of MR abound. To overcome barriers, tools that promote the systematic exchange of information, facilitate shared understanding, and promote patient-centeredness are needed to improve the outpatient MR process.

PATIENT-REPORTED QUALITY OF CARE IN LOW- AND MIDDLE-INCOME COUNTRIES: A FOUR-COUNTRY SURVEY OF PATIENT EXPERIENCE

June-Ho Kim^{2, 1}; Griffith A. Bell²; Hannah Ratcliffe²; Leah Moncada³; Stuart R. Lipsitz^{1, 2}; Dan Schwarz²; Lisa R. Hirschhorn^{4, 2}; Asaf Bitton^{2, 1}. ¹Brigham and Women's Hospital, Boston, MA; ²Ariadne Labs, Brigham & Women's Hospital and Harvard T.H. Chan School of Public Health, Boston, MA; ³RIWI Corp, Toronto, ON, Canada; ⁴Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #3185437)

BACKGROUND: Patient experience is a major tenet of high-quality health care but is rarely measured in low- and middle-income countries (LMICs). We assessed patient-reported experience, quality of care (QOC), and characteristics of people who sought care in four LMICs.

METHODS: We analyzed a 2016 web-based survey administered in India, Kenya, Mexico, and Nigeria. The main outcome was patient-reported QOC, dichotomized into categories of "excellent" vs "not excellent." To quantify patient experience, we created a "responsiveness" index, derived from the WHO Health Systems Responsiveness framework, using questions assessing respect from providers, ability to understand the provider's advice, facility cleanliness, and rating of wait time. Covariates included age, sex, education, country, urban/rural status, person seeking care, reason for seeking care, type of provider, site of care, and facility type. We used multivariable Poisson regression to estimate adjusted prevalence ratios (aPR) for excellent QOC across levels of respondent characteristics and quintiles of responsiveness index.

RESULTS: From a survey population of 61,987, 17,441 respondents sought care in the past 6 months and 5,407 of those (31%) completed the survey. Respondents were generally young (86% age<45), male (67%), well-educated (57% with post-secondary degree), and urban-dwelling (68%). For their most recent care-seeking experience, respondents most often saw a specialist or primary care provider (49% and 25%, respectively). Wide inter-country variability was seen for care-seeking at private health facilities (65% in India vs 45% in Mexico). Most patients in India and Mexico reported being part of a prepayment plan (i.e. receiving medical aid or insurance) in contrast to Nigeria and Kenya. Nigeria had the most respondents reporting excellent QOC (31%) compared to only 19% in India and Mexico. In adjusted models, people living in rural areas were more likely to report excellent QOC compared to their urban

counterparts (aPR 1.15, 95% CI 1.02, 1.31) while those who saw a specialist were more likely than those who saw a primary care provider (aPR 1.49, 95% CI 1.27, 1.74). Respondents with prepayment plans (aPR 1.27, 95% CI 1.13, 1.43) and those who sought care in a private facility (aPR 1.40, 95% CI 1.23, 1.59) reported higher QOC. Mean responsiveness scores ranged from 0.64 to 0.66 on a scale of 0 to 1 in India, Kenya, and Mexico while Nigeria had a mean of 0.71. Respondents who experienced the highest responsiveness reported higher QOC than those who experienced lower responsiveness (aPR 8.38, 95% CI 7.39, 9.50).

CONCLUSIONS: Higher patient-reported quality in four LMICs was associated with seeking specialty care compared to primary care and private sector care compared to public sector; having a prepayment plan; and experiencing higher responsiveness. Targeting interventions to improve health system responsiveness in settings of care with lower patient-reported quality could improve patients' overall experience in LMICs.

PATIENTS' REPORTS OF HARM FROM FAILURES OF CARE COORDINATION

Lisa M. Kern¹; Evgeniya Reshetnyak¹; Lisandro Colantonio²; Paul Muntner²; J. David Rhodes²; Lawrence P. Casalino¹; Mangala Rajan¹; Michael Pesko³; Jacqueline Marino¹; Laura C. Pinheiro¹; Monika M. Safford¹. ¹Weill Cornell Medicine, New York, NY; ²University of Alabama at Birmingham, Birmingham, AL; ³Georgia State University, Atlanta, GA. (Control ID #3168018)

BACKGROUND: Previous studies show that some patients report dissatisfaction with the extent to which their providers coordinate their care. However, it has not been clear how significant any gaps in care coordination have been and whether they have led to undesirable outcomes. We sought to determine the frequency of patient-reported harm from perceived gaps in care coordination.

METHODS: We conducted a survey on care coordination within the REasons for Geographic and Racial Differences in Stroke (REGARDS) study, a population-based, ongoing, prospective cohort study of community-dwelling adults, who were recruited between 2003 and 2007. The 21-question care coordination survey module was administered to REGARDS participants 65 years old during a routine follow-up phone call between August 2017 and October 2018. The module asked about numbers of ambulatory visits and providers in the past year, perceptions of care coordination, and the occurrence of four outcomes (repeat tests, drug-drug interactions, emergency department (ED) visits, and hospitalizations). Participants experiencing outcomes were asked if they thought the outcomes were preventable with better care coordination. If a respondent reported poor care coordination in response to one or more (out of 7) questions on perceptions of care coordination, we considered the respondent to have reported a "gap" in care coordination. Among those who reported having 2 visits and 2 providers in the previous year (as a proxy for being at risk for problems with care coordination), we used logistic regression to determine associations between self-reported gaps in care coordination and self-reported outcomes that could have been prevented with better care coordination, adjusting for participants' demographic and clinical characteristics.

RESULTS: Of 13,208 REGARDS participants approached, 10,418 (79%) completed the care coordination survey module and were 65 years old. The average respondent was 77.2 years old (SD 6.9); 57% were women, and 36% were black. The average respondent reported having had 5.2 ambulatory visits (SD 6.4) across 2.8 ambulatory providers (SD 2.5) the previous year. Of those with 2 visits and 2 doctors the previous year (N = 7,075), 38% reported one or more gaps in care coordination and 10% reported at least one outcome that could have been prevented with better care coordination (3% reported repeat tests, 6% drug-drug interactions, 1% preventable ED visits, and 1% preventable hospitalizations). Participants with one or more gaps in care coordination were more likely to report preventable outcomes than those without gaps in care coordination (adjusted odds ratio 1.52; 95% confidence interval 1.24, 1.85).

CONCLUSIONS: Patients report that gaps in care coordination are common

and that these gaps often lead to undesirable outcomes. Future interventions to improve care coordination should engage patients directly, as patients may be able to both identify the problem and contribute to a solution.

PEER-LED SOCIAL MEDIA BASED HEALTH CAMPAIGN: PERSONALIZED DIGITAL CONTENT AND STRATEGIES ASSOCIATED WITH HIGHER LEVELS OF ENGAGEMENT

Lawrence Gross¹; Minia N. Rios Gutierrez²; Keith J. Horvath³; Viraj V. Patel². ¹Albert Einstein College of Medicine, Bronx, NY; ²Montefiore Health System / Albert Einstein College of Medicine, Bronx, NY; ³University of Minnesota, Minneapolis, MN. (Control ID #3179523)

BACKGROUND: The attributes of user-driven postings to a virtual community wall can influence engagement with online health interventions to support behavior change. Because techniques for optimal engagement of Black and/or Latinx men who have sex with men (BLMSM) are unknown, we analyzed the effects of digital post characteristics on engagement levels using data from a peer-delivered, social-media based HIV prevention intervention.

METHODS: 10 BLMSM peer-leaders participated in an online health intervention in New York City disseminating pre-determined tailored health messages ("posts") over six-weeks to 164 BLMSM participants from their Facebook networks in private Facebook groups. We categorized the standardized posts (developed by PLs) based on content types (video, image, infographic, text-only, or article) and engagement strategies used (posing a question, hashtag, tagging participants, emoji, celebrity references, and community [posts featuring people of color]). We calculated engagement scores by summing each post's likes and comments, and weighted by a ratio of total number of likes, comments, and potential viewers across all post. We then calculated mean engagement scores (MES) for each categorization and compared using ANOVA and multivariable regression (shown as (95%CI)).

RESULTS: There were a total of 459 posts, consisting of the following content types: 113 videos, 126 images, 67 infographics, 54 text-only and 99 articles. Distribution of engagement strategy was: 148 question, 120 hashtag, 35 tagging, 59 emoji, 10 celebrity, and 161 community. MES across all categories ranged from 8.8-59. When comparing posts by content type, text-only posts had the highest MES (23.1) and posts of articles had the lowest (8.8) (p=0.04). Among strategies, tagging participants had the greatest MES (59), while using an emoji had the lowest MES (16). MES increased with the number of strategies used (e.g., posts not using an identifiable strategy (MES=6.25) to posts using 4 strategies (MES=40.9)). In multivariable analyses of content-types, only text posts had significantly higher engagement (0.14 (0.05-0.24)) than articles. In multivariable analysis of engagement-strategies, tagging (0.49(0.39-0.58)) and questions (0.1(0.05-0.15)) were more likely to have higher MES compared to not using an identifiable engagement-strategy (p<0.01). Sensitivity analysis which considered the effect of PLs on MES did not change findings.

CONCLUSIONS: In an online health intervention for BLMSM, personalized content types and engagement strategies were most successful at eliciting greater engagement with materials. Text-only posts can be more easily tailored than other content types to address specific groups or individuals. Tagging and posing questions may increase engagement by making it socially desirable to respond to peers online. Online health interventions should consider personalizing digital contents to enhance engagement.

PERCEIVED BARRIERS AND FACILITATORS TO CONTRACEPTIVE USE AMONG WOMEN VETERANS IN THE ECUUN STUDY

Tierney Wolgemuth¹; Maris Cuddeback¹; Keri L. Rodriguez³; Xinhua Zhao⁴; Sonya Borreiro². ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²University of Pittsburgh and VA Pittsburgh, Pittsburgh, PA; ³VA Pittsburgh Healthcare System, Pittsburgh, PA; ⁴VA Pittsburgh

HealthCare System, Pittsburgh, PA. (Control ID #3138503)

BACKGROUND: Despite coverage of the full range of effective contraceptive methods through the Veteran's Affairs Healthcare System (VA), women Veterans experience a high burden of unintended pregnancy, with proportions comparable to the general United States population. Although many studies evaluate factors affecting contraceptive use, little is known about influences specific to or prominent among women VA-users. This qualitative study seeks to characterize barriers and facilitators to contraceptive use experienced by women Veterans using VA services, as well as elicit their suggestions to improve VA contraceptive care.

METHODS: Semi-structured telephone interviews were conducted with a purposefully-selected national sample of 187 women Veterans aged 18-44 at risk of unintended pregnancy who receive primary care in VA to explore their perspectives and experiences with contraceptive care. The sampling strategy sought to ensure that we heard the perspectives of women with potentially vulnerable demographic or clinical characteristics, including women in ethnic/ racial minority groups, and/ or with medical or mental health conditions or a history of military sexual trauma. Interviews were transcribed verbatim and transcript narratives analyzed using content analysis and the constant comparison method.

RESULTS: Five distinct themes emerged as barriers or facilitators to contraceptive use depending on participants' VA facility and provider, and participants offered suggestions to address issues pertaining to each theme. Most participants (56%) noted low *efficiency of care* as a main factor, especially poor appointment access and difficulty navigating the VA system. Others (39%) expressed that limited *contraceptive counseling and patient education* acted as barriers, and requested classes and support groups to enhance understanding. About a third of women (34%) noted that low *patient awareness of services* impeded contraceptive care and suggested improved advertising to both servicewomen and Veterans. Some (32%) stressed poor *interaction with provider* as a prominent barrier, specifically noting provider inattentiveness and lack of expertise. Finally, 31% noted feeling like an outsider at VA, and emphasized fostering a *female-friendly environment* by creating a separate space for women's clinics to remove discomfort associated with seeking contraceptive care.

CONCLUSIONS: These findings suggest that despite widespread access to low-cost contraception, many women Veterans experience barriers to accessing high-quality contraceptive care. While barriers and facilitators were unique to individual VA facilities and providers, women offered concrete suggestions that could make access to high-quality services more uniform, including enhancing patient education on contraceptive options; expanding advertising of contraceptive services to women Veterans; and providing a separate women's clinic to ensure women Veterans feel comfortable seeking contraceptive care.

PERCEIVED SUPPORT DURING AND AFTER A WEIGHT LOSS MAINTENANCE INTERVENTION: SECONDARY ANALYSIS FROM THE MAINTAIN-PC TRIAL

Skylar Larsen⁵; Maribel Cedillo¹; Polina Kukhareva¹; Cindy L. Bryce²; Bethany Barone Gibbs²; Jonathan Arnold³; Rachel Hess⁴; Laurey R. Simkin-Silverman²; Gary Fischer²; Molly Conroy¹. ¹University of Utah, Salt Lake, UT; ²University of Pittsburgh, Pittsburgh, PA; ³University of Pittsburgh Medical Center, Pittsburgh, PA; ⁴University of Utah, Salt Lake City, UT; ⁵Univesrity of Utah, Salt Lake City, UT. (Control ID #3180303)

BACKGROUND: Many patients with obesity achieve significant weight loss only to regain. Weight loss has been well studied, but less is known about weight loss maintenance, including patients' perceptions of support received and desired.

METHODS: We conducted a secondary analysis of participant feedback data from the Maintaining Activity and Nutrition through Technology-Assisted Innovation in Primary Care (MAINTAIN-pc), a randomized controlled trial of an electronic health record (EHR)-based intervention for weight loss maintenance. Participants were randomized into coaching or

tracking groups. Both had access to EHR tools (flowsheets for tracking weight, diet, and physical activity, standardized surveys, and reminders) via the patient portal. The coaching group received personalized coaching via the EHR for two years. The primary care providers (PCP) of coaching group participants received real-time progress reports and notification of significant weight gain or loss. Participants provided feedback at 6, 12, 24, and 30 months. We evaluated responses about EHR ease of use and perceptions of sources of support after intervention (i.e., months 25-30) in both groups and preferences for communication and connectedness with coaches in the coaching group.

RESULTS: 136 (73.5%) participants completed feedback at 24 months and 115 (62.2%) at 30 months. Respondents were 74% female and 88% white. The majority of participants (78.7%) indicated the EHR was "easy to use" (80% coaching; 77.3% tracking; p=1.0). Many coaching participants (44.3%) preferred communicating through the EHR alone. However, additional 'in-person communication' was preferred by 41.4% of the coaching group (27.6% individual, 31.0% group and 41.4% either). In addition, 71% of coaching group participants selected their coach as a source of support and 54.8% stated a moderate/strong connectedness with coach. PCPs were viewed as a source of support in 38.7% of coaching and 22.6% of tracking group (p=0.1) and health professionals (PCP and other health care professionals (e.g., coaches, nurses)) were viewed as a source of support in 41.9% of the coaching group and 22.6% in tracking (p=0.046). The perception that 'no support was required after intervention' was indicated by 24.2% coaching and 24.5% tracking (p=1.0). Finally, reported use of commercial online programs after intervention was low (4.8% coaching; 7.5% tracking; p=0.83).

CONCLUSIONS: An EHR-based format for a weight maintenance loss intervention is appropriate based on feedback about ease of use and perceptions of coach support and connectedness. Coaching participants were more likely to feel supported by a health professional than those in the tracking group. However, coaching participants also indicated a desire for in-person support in addition to online coaching. Future weight maintenance interventions may consider adding optional in-person support to remote communication.

PERCEPTIONS AND PERFORMANCE OF LEARNERS IN AN INTERPROFESSIONAL COLLABORATIVE PRACTICE MODEL

Alanna J. Diamond¹; Stephanie Cornell¹; Glennette Castillo¹; Erika Bowen⁴; Lauren S. Penney⁵; Luci Leykum³; Temple Ratcliffe². ¹University of Texas Health - San Antonio, San Antonio, TX; ²UTHSCSA, San Antonio, TX; ³STVHCS / UTHSCSA, San Antonio, TX; ⁴UT Health San Antonio, San Antonio, TX; ⁵Veterans Health Administration, South Texas Veterans Health Care System (STVHCS), San Antonio, TX. (Control ID #3184203)

BACKGROUND: With increased focus on Interprofessional education (IPE) and interprofessional collaborative practice (IPCP), more settings are implementing these care models. While patients appreciate IPCP, learner acceptance has been more variable. In 2015, we initiated an IPCP care model (Collaborative Care - CC), which incorporates nurses, physicians, students, pharmacists, social workers, physical therapists, patients and families. Early learner feedback noted improved communication with patients, families, and other professions, but also reflected educational concerns regarding medical knowledge and teaching on rounds. We enhanced orientation for residents and medical students, and after building our experience with CC, revisited learner perceptions in 2017. We expected learner perceptions of their educational experiences would improve. We also examined student NBME exam scores between traditional and CC teams to assess whether differences in medical knowledge as measured by NBME scores existed.

METHODS: We conducted semi-structured learner interviews and analyzed NBME scores. Interviews were conducted between August and October 2017. All interviews were recorded, transcribed, coded and

inductively analyzed using MAXQDA software by three trained coders (AC, SC, GC). Themes were developed and compared to 2015. NBME Internal Medicine subject exam scores were compared between medical students on CC teams and non-CC teams from January 2015 through July 2018 using Student's t-test (Stata IC, version 15).

RESULTS: Interviewees included seven medical students (39%), eight PGY-1 residents (44%) and three upper level (PGY-2, PGY-3) residents (17%). Themes previously found in the 2015 interviews were reiterated in 2017, including improved communication between patients and providers, feelings of uncertainty during new situations, strategies for adaptation, and loss of educational opportunities during rounds. Mean NBME scores were 75.82 for medical students on IPCP teams (N=103) and 76.32 for medical students on non-IPCP teams (N=661). No significant difference between means was found ($p=0.57$).

CONCLUSIONS: Learner concerns about educational loss in IPCP settings persisted despite equivalent NBME performance. While learners appreciated increased opportunities to improve communication skills with patients and other health professionals, they perceived these opportunities as trade-offs with profession-specific knowledge acquisition. While these concerns are not unique to IPCP (similar concerns have been reported in other profession-specific bedside rounding interventions), they are complex and difficult perceptions to improve. More work should be done to make evaluation of IPCP competencies similarly robust and valued compared with evaluation of profession-specific competencies including medical knowledge. Hidden curricular lessons regarding the relative decreased value of interprofessional competencies may also need to be addressed.

PERCEPTIONS OF SOCIAL DETERMINANTS OF HEALTH AMONG INTERNATIONAL MEDICAL GRADUATES: A QUALITATIVE STUDY

Raman Singhal; Aathira Sreenivasan; Sumaira Zareef; Grace Kajita. Montefiore Medical Center, Bronx, NY. (Control ID #3184880)

BACKGROUND: In 2018, non-U.S. citizen International Medical Graduates (IMGs) filled over a quarter of internship slots in categorical internal medicine programs in the U.S. Little evidence exists to guide physician educators in teaching IMGs about the unique barriers to care faced by underserved communities in the U.S. It also remains unknown to what extent IMGs are aware of and interested in addressing the social determinants of health (SDH) with their patients in the U.S.

METHODS: In this qualitative study, PGY2 IMG's from an Internal Medicine residency program in Bronx, NY were interviewed in one-hour long, semi-structured focus groups of 6 residents each. Interview questions sought to compare patient characteristics and health care delivery in home countries and the U.S., to understand how previous experiences affect IMGs' approach to patient care in the U.S. Perspectives on SDH in the U.S. were also elicited during focus groups, based on their one year of completed training here. Interviews were audio-recorded and professionally transcribed. Transcripts were coded and analyzed by 4 researchers, using a thematic analysis approach.

RESULTS: 24 PGY2 IMG residents (100%) agreed to participate. Of these, 75% attended medical school in South Asia. Three overarching themes emerged. First, participants expressed judgments that U.S. patients do not value their health and mistrust doctors, unlike patients in their home countries: "(U.S. patients) have so many privileges and still, they don't take care of themselves. They are taking things for granted, and it's kind of frustrating sometimes"; "This was shocking to me when I came over here. People do not respect doctors at all. They think (we) are just trying to suck money out of their pockets and prolong their illness." Second, participants perceived social determinants of health to be less severe in the U.S. compared to their home countries: "The Bronx population may be poor, but people don't starve to death...back home, people do die of hunger." Third, participants were concerned that the responsibility for good health falls solely on the individual in the U.S. and acknowledge that patients may face various obstacles: "The reason they're missing appointments is because

they're having two jobs or they're single parents taking care of their children, barely enough time to sleep." This is in stark contrast to the rich family support that is the norm for patients in home countries.

CONCLUSIONS: IMG resident patient care in the U.S. is strongly experienced in the context of patient care in home countries. IMGs are aware of SDH in both locations, and comparisons are commonplace. Although SDH are viewed as less prominent barriers to care in the U.S., residents are also able to empathize with the difficulties U.S. patients face in taking care of their health. This needs assessment will inform a curriculum in SDH tailored for IMG trainees, which will help them understand the scope of SDH specific to the U.S. and develop skills to assess and manage SDH.

PERSPECTIVE-TAKING IN MEDICAL EDUCATION: A QUALITATIVE ANALYSIS OF INTERNAL MEDICINE RESIDENTS' ATTITUDES TO A NOVEL CURRICULUM

Brianna Rossiter¹; Melissa McNeil¹; Gaetan Sgro². ¹University of Pittsburgh Medical Center, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #3186245)

BACKGROUND: Residency is marked both by intense knowledge acquisition, personal growth, and by increasing levels of burnout and cynicism. The latter erode empathy and undermine the altruistic motivations that led to a medical career path. Interactions with so-called "challenging" patients in the ambulatory setting are often cited as drivers of burnout and cynicism. Perspective-taking (PT) is a cognitive skill defined as "an understanding of other people's mental states" and has been studied as a way to cultivate empathy. The purpose of this study was to explore internal medicine residents' attitudes to the implementation of a PT exercise in an ambulatory curriculum.

METHODS: The PT curriculum took place within the PGY3 Ambulatory rotation of the UPMC Internal Medicine Residency, which all PGY3 residents complete as part of their training. The curriculum included the PT writing exercise itself and a facilitator-guided, de-brief session. Residents were then invited to participate in an interview to explore their attitudes to the curriculum. Two researchers developed a code book based on the interviews, coded, and assessed inter-rater reliability. Thematic analysis was completed with consultation of a qualitative research group.

RESULTS: Thirteen residents completed interviews and were analyzed. Preliminary emerging themes include: appreciation for a novel approach to understanding challenging patients, ambivalence over the best way to engage in self-reflection in medical training, finding value in co-residents' contribution to the de-brief session, identification of PT as a way to navigate challenging patient interactions, and defining empathy as an extremely important characteristic of a physician.

CONCLUSIONS: A clinical experience in PT, encouraging resident reflection, provides a novel approach for probing empathy, a challenging construct to teach in medical education. Residents appreciated the opportunity to reflect about challenging patient encounters and found value in de-briefing with their peers. These attitudes support the need for future work in using PT as a cognitive means for maintaining empathy in medical training.

PERSPECTIVES ON DEPRESCRIBING CARDIOVASCULAR MEDICATIONS: A NATIONAL SURVEY OF INTERNISTS, CARDIOLOGISTS, AND GERIATRICIANS

Timothy Anderson¹; Parag Goyal³; Michael A. Steinman²; Michael W. Rich⁴. ¹University of California, San Francisco, San Francisco, CA; ²SF VA Medical Center, San Francisco, CA; ³Weill Cornell Medicine, New York, NY; ⁴Washington University School of Medicine in St. Louis, St. Louis, MO. (Control ID #3186031)

BACKGROUND: Polypharmacy in older adults is prevalent and harmful. The practice of deprescribing to reduce harms from unnecessary medication use is an increasingly recognized approach to comprehensive, patient-centered care for older adults. Deprescribing may encompass stopping cardiovascular (CV) medications including statins, antiplatelets, and antihypertensives.

METHODS: To understand physician perspectives on deprescribing CV

medications and how they may differ between specialties we conducted a cross-sectional survey of internists, cardiologists and geriatricians drawn from a random sample of members of the American College of Physicians (June-August 2018). Physicians were surveyed on current deprescribing practices, reasons for deprescribing, barriers to deprescribing, and discussion of deprescribing with other providers. Respondents were asked to identify medications they would consider deprescribing in hypothetical clinical cases.

RESULTS: The response rate varied between specialties: 26% for internists (182/771), 12% for cardiologists (87/717) and 26% for geriatricians (184/711). Demographics were similar across groups except for fewer female respondents among cardiologists. In the month prior to being surveyed 83% of internists, 93% of geriatricians and 85% of cardiologists reported considering stopping a CV medication for a patient. However, all specialties were less likely to report discussing discontinuing a CV medication with another provider (39%, 55%, and 41% respectively). Reported reasons for deprescribing were highly variable, with the most common reasons being medication side effects (>60% of respondents for all specialties) and among geriatricians limited life expectancy (>75% of respondents). Less frequently identified reasons for deprescribing included medication cost, polypharmacy, patient request, and lack of medication indication (all <30%). The most common barriers reported were similar across specialties and included concerns of patient reluctance and concerns of interfering with other physicians' treatment plans. In hypothetical cases, specialties were similarly likely to stop medications were patients reported specific side effects. Compared to internists, cardiologists were less likely and geriatricians were more likely to consider stopping CV medications when patients reported no concerns, a desire to decrease pill burden, a new diagnosis of metastatic malignancy, or a new diagnosis of dementia.

CONCLUSIONS: The majority of internists, cardiologists, and geriatricians reported consideration of deprescribing CV medications in their recent clinical practice, however reasons for deprescribing varied between groups which may reflect differing professional society guidelines. Common barriers included concerns of patient reluctance and concerns of interfering with other physicians' plans. These results indicate the need for additional efforts to develop communication strategies to improve the uptake of deprescribing.

PHARM-MD; AN OPEN-LABEL, RANDOMIZED CONTROLLED PHASE II STUDY TO EVALUATE THE EFFICACY OF A PHARMACIST MANAGED DIABETES CLINIC IN HIGH-RISK DIABETES PATIENTS

Alexandra Halalau^{1, 2}; Jordan Bushman¹; Jaspreet Hehar¹; Janna Fett¹; Scott Keeney³; Daniel Shelden⁴. ¹Beaumont Health, Troy, MI; ²Oakland University William Beaumont School of Medicine, Rochester, MI; ³Baylor Scott & White, Kileen, TX; ⁴University of Michigan, Ann Arbor, MI. (Control ID #3165157)

BACKGROUND: Over 30 million Americans are currently living with diabetes and approximately 1.5 million cases are being diagnosed each year. The United States lags behind other developed countries on diabetes life expectancy and disease-related deaths. Previous studies demonstrated that for each 1% reduction in hemoglobin A1c (HbA1c), there was a corresponding 14% reduction in myocardial infarction, 12% reduction in stroke, and a 37% reduction of microvascular complications. Our retrospective data showed that patients who received care in a pharmacy managed diabetes clinic (PMDC) had a decrease at six months in HbA1c of 3.2% versus 1.2% in the standard care cohort ($p=0.044$). Our hypothesis is that a PMDC will have a significant positive impact on diabetes measures and will result in higher quality care at a lower price.

METHODS: This phase II trial is currently enrolling patients and randomly assigning them to one of two groups: standard of care (SOC) or SOC+PMDC. The PMDC consists of six extra visits with the pharmacists that are focused on patient-identified diabetes management gaps, goals and medication adjustments. Inclusion criteria are: patients older

than 18 years of age with a diagnosis of type 2 diabetes mellitus and a HbA1c >9%, who are established with a primary care resident and who have not been seen in the PMDC within the last 3 months. A sample size of 86 patients was calculated to detect a 1.0 mean difference in HbA1c between the groups with 80% power at a $p<0.05$ significance. The primary outcome is the change in HbA1c, measured at 3, 6 and 12 months. Secondary outcomes include the impact on all diabetes core measures, patient quality of life, harms and cost impact related to the intervention.

RESULTS: At the time of preliminary analysis, 54 patients were enrolled, 28 in the intervention group and 26 in the control group. Baseline characteristics were not significantly different between the two groups. Mean HbA1c at baseline was 11.5 in the intervention group and 11.0 in the control group. At 3 months, the mean HbA1c decreased to 8.0 in the intervention group versus 9.3 in the control group. Difference in means from baseline to 3 months is -3.5 and -1.7 in intervention and control group, respectively. Retinopathy screening was performed in 12 v. 18 patients in the intervention and control groups, respectively ($p=0.045$). No significant differences in remaining secondary outcomes were observed.

CONCLUSIONS: If our study demonstrates improved patient outcomes with the utilization of pharmacists, a PMDC may become an integral part in the care of high-risk diabetic patients. This may help reduce the economic burden of the disease, improve life expectancy and disease related deaths. Complete data analysis will be presented at the conference.

PHARMACOTHERAPY FOR COCAINE USE DISORDER - A SYSTEMATIC REVIEW AND META-ANALYSIS

Brian Chan^{1, 2}; Karli Kondo^{4, 3}; Michele Freeman⁴; Chelsea K. Ayers⁴; Jessica Montgomery⁴; Robin Paynter⁴; Devan Kansagara^{3, 4}. ¹OHSU, Portland, OR; ²Central City Concern, Portland, OR; ³Portland VA Medical Center, Portland, OR; ⁴Portland VA Healthcare System, Portland, OR. (Control ID #3186054)

BACKGROUND: Currently there are no accepted FDA-approved pharmacotherapies for cocaine use disorder (CUD), though numerous medications have been tested in clinical trials. We conducted a systematic review and meta-analysis of the effectiveness of pharmacotherapy for cocaine use disorder.

METHODS: We searched multiple data sources (MEDLINE, PsycINFO, and Cochrane Library) through November 2017 for systematic reviews and randomized controlled trials (RCTs) of pharmacological interventions in adults with CUD. We combined the findings of trials with comparable interventions and outcome measures in random-effects meta-analyses. We assessed the risk of bias of individual trials and the strength of evidence for each outcome using standardized criteria. Outcomes of interest comprised abstinence, defined as 2 or more consecutive weeks with negative urine drug screens (UDS); overall use, analyzed as the proportion of UDS specimens that were negative; and retention, defined as the proportion of randomized patients who completed treatment.

RESULTS: We found 7 systematic reviews and 47 RCTs that met inclusion criteria studying 66 different drugs or drug combinations. Antidepressants were the most widely studied drug class (38 RCTs) but appear to have no effect on cocaine use or treatment retention. Increased abstinence was found with bupropion (2 RCTs: RR 1.63, 95% CI 1.02 to 2.59), topiramate (2 RCTs: RR 2.56, 95% CI 1.39 to 4.73), and psychostimulants (14 RCTs: RR 1.36, 95% CI 1.05 to 1.77), though the strength of evidence for these findings was low. Antipsychotics improved treatment retention (8 RCTs: RR 1.33, 95% CI 1.03 to 1.75) and the strength of evidence was moderate.

CONCLUSIONS: Most of the pharmacotherapies studied were not effective for treating CUD. Bupropion, psychostimulants, and topiramate may improve abstinence, and antipsychotics may improve retention. Future trials of medications with behavioral interventions may be warranted.

PHARMACOTHERAPY FOR METHAMPHETAMINE/

AMPHETAMINE USE DISORDER - A SYSTEMATIC REVIEW AND META-ANALYSIS

Brian Chan^{1, 2}; Karli Kondo⁴; Michele Freeman⁴; Chelsea K. Ayers⁴; jessica Montgomery⁴; Robin Paynter⁴; Devan Kansagara^{3, 4}. ¹OHSU, Portland, OR; ²Central City Concern, Portland, OR; ³Portland VA Medical Center, Portland, OR; ⁴Portland VA Healthcare System, Portland, OR. (Control ID #3186086)

BACKGROUND: Addiction to methamphetamine/amphetamine (MA/A) is an increasing public health problem. Currently, there are no accepted FDA-approved pharmacotherapies for MA/A use disorder, though numerous medications have been tested in clinical trials. We conducted a systematic review and meta-analysis of the effectiveness of pharmacotherapy for MA/A use disorder.

METHODS: We searched multiple data sources (MEDLINE, PsycINFO, and Cochrane Library) through November 2017 for systematic reviews (SRs) and randomized-controlled trials (RCTs) of pharmacological interventions in adults with MA/A use disorders. The outcomes of interest comprised abstinence, defined as 2 or more consecutive weeks with negative urine drug screens (UDS); overall use, analyzed as the proportion of UDS specimens that were MA/A-negative; and retention, defined as the proportion of randomized patients who completed treatment. We combined the findings of trials with comparable interventions and outcome measures in random-effects meta-analyses. We assessed the risk of bias of RCTs, and the overall strength of evidence for each outcome using standardized criteria.

RESULTS: 14 RCTs and 1 SR of pharmacotherapies for MA/A use disorder met our inclusion criteria. 14 different drugs were studied, including antidepressants, antipsychotics, psychostimulants, anticonvulsants, and opioid antagonists. Although there was no evidence of benefit for psychostimulants overall, there was low strength evidence from 2 RCTs that methylphenidate may reduce MA/A use. Antidepressants had no effect on abstinence or retention based on moderate to high strength evidence. Studies of anticonvulsants, antipsychotics (ariPIPrazole), and opioid antagonists (naltrexone) provided either low strength evidence of no effect on the outcomes of interest, or insufficient evidence to draw conclusions. Many of the studies had high or unclear risk of bias.

CONCLUSIONS: Most pharmacotherapies were ineffective in treating MA/A use disorder. Novel pharmacotherapies specific to the neurobiology of MA/A use disorders need to be developed to supplement existing behavioral interventions for this emerging epidemic.

PHYSICIAN CHARACTERISTICS CORRELATE WITH PATIENT READMISSION RATES

Eileen Hennrikus¹; Michael Skolka²; Mallory Schaffer³. ¹Penn State College of Medicine, Hershey, PA; ²Penn State Health, Hershey, PA; ³University of Pittsburgh, Pittsburgh, PA. (Control ID #3163053)

BACKGROUND: The 7- and 30-day patient readmission rates are tracked by hospitals and are used as a metric to measure physicians' quality of patient care. Several tools currently predict and prevent early readmission rates based on patient-specific characteristics. However, few studies have demonstrated if physician-specific characteristics play a role. The purpose of this study is to assess if physician characteristics correlate with patient readmission rates.

METHODS: In a five-year retrospective chart review, 31 internal medicine physicians and their hospital discharges were recorded for a total of 15,933 hospital discharges at one academic institution. Each physician's yearly 7-day, 8-30day (excluding the first 7 days), and 30-day readmission rates was compared to all the other physicians' rates. Each readmission rate was also correlated with years of post-graduate clinical experience, patient discharge volume, physician gender, and fiscal year. All analyses were performed using SAS 9.4.

RESULTS: The 7-day readmission rates did not correlate with the 8-

30 day rates ($p=0.155$). Individual physicians had significantly different rates for all readmission categories ($p=0.001$ - 0.010). However, the rates were not related to gender or years after post-graduate training. Physician patient volume was the only identified characteristic that significantly correlated with readmission rates. Physicians who discharged 100 patients in a year had a higher 7-day readmission rate, 8.24% (6.76, 9.71), compared to physicians who discharged 101-200 (5.75%, $p=0.047$), 201-300 (5.83%, $p=0.033$), or 301 (5.49%, $p=0.024$) patients in a year. The volume of patient discharges did not influence physician 8-30 day readmission rates.

CONCLUSIONS: Individual physician characteristics statistically correlate with patient readmission rates. A critical level of a physician's yearly hospital activity, as reflected by the number of patient discharges per year (>100) significantly results in lower 7-day readmission rates. Gender, post-graduate years of clinical experience, and fiscal year were not significant. Physician hospital activity did not affect 8-30 day readmissions, suggesting that the unidentified physician characteristics that influence the 8-30 day readmission rate are different than those physician characteristics that influence the more immediate 7-day readmission rates.

PHYSICIAN HOME VISITS AFTER HOSPITAL DISCHARGE: A PILOT RANDOMIZED CONTROLLED TRIAL

David M. Levine¹; Kei Ouchi¹; Mary R. Paz³; Kimberly P. Burke²; Jeffrey L. Schnipper¹. ¹Brigham and Women's Hospital, Boston, MA; ²Brigham and Women's Hospital, Brighton, MA; ³Brigham and Women's Hospital, BOSTON, MA. (Control ID #3184860)

BACKGROUND: Transition from acute care to home is a time marked by new or worsening symptoms, readmission, and adverse events. Many interventions have attempted to improve the transition to home, including nurse, nurse practitioner, and pharmacist home visits, with inconsistent results. To our knowledge, no recently evaluated intervention has involved a physician home visit. Decades ago, physician home visits formed the backbone of care for the most vulnerable patients. We hypothesized that a physician home visit following discharge would reduce new or worsening symptoms and readmission.

METHODS: We performed a pilot randomized controlled trial of a single physician home visit within 4 days of discharge from an acute care episode vs usual care. We enrolled patients who were being discharged to home and whose inpatient care team felt for any reason a physician home visit would be of benefit. Patients had to live within 5 miles of the hospital. After enrollment, patients were randomized 1:1 to a physician home visit vs usual care. The content of the home visit was left entirely to the discretion of the physician, although s/he was provided materials for best practices in home visits and medication reconciliation based on prior research. The primary endpoint was having at least one new or worsening symptom at 30-days post-discharge, captured by a structured phone interview used in prior research. Our secondary endpoints included 30-day readmission, 30-day emergency department (ED) utilization, 14-day PCP utilization, and readiness to transition via the Care Transition Measure (CTM)-3. We performed an intention-to-treat analysis and compared groups by Fisher exact test.

RESULTS: We enrolled 51 patients (26 home visits; 25 controls). Patients who received home visits had a median age of 65, 65% were female, 81% underrepresented minorities, and 35% had less than a high school education. The control group was similar, except it had fewer underrepresented minorities (68%). There was no difference in new or worsening symptoms at 30-days between the home visit (44%) and control (42%) group ($p=0.66$). The home visit group had nonsignificant trends toward fewer 30-day readmissions (23% vs 36%, $p=0.37$), fewer 30-day ED presentations (8% vs 12%, $p=0.42$), and more often saw their PCP within 14 days (31% vs 25%; $p=0.39$). The CTM-3 rating was the same for both groups (median, 9 out of 12). Nine intervention patients (35%) had medication changes as a result of their physician visit.

CONCLUSIONS: In this pilot randomized controlled trial of a physician home visit following discharge from the hospital, patients who received a visit had a nonsignificant trend toward reduced readmission and ED presentation and better follow-up with their PCP, but no difference in self-reported symptoms or readiness to transition. To our knowledge, this is the first test of a physician home visit following discharge. Refinement of the intervention and replication in a larger cohort is needed.

PHYSICIAN SATISFACTION WITH HEALTH PLANS: RESULTS FROM A NATIONAL SURVEY

Natasha Parekh^{1,2}; Sheryl Savage³; Amy Helwig⁴; Patrick Alger³; Sandra McAnallen⁴; William H. Shrunk⁴. ¹University of Pittsburgh Medical Center, Pittsburgh, PA; ²UPMC Center for High-Value Health Care, Pittsburgh, PA; ³SPH Analytics, Alpharetta, GA; ⁴UPMC Insurance Services Division, Pittsburgh, PA. (Control ID #3184380)

BACKGROUND: Physician satisfaction is associated with patient satisfaction, adherence to treatment recommendations, and quality. However, burnout is prevalent, and physician experience with health plans is likely a key contributor. Our existing knowledge of physician satisfaction with health plans, however, is limited, mixed and outdated. We therefore explored physician satisfaction with health plans, and assessed which physician and plan characteristics are associated with greater satisfaction.

METHODS: We conducted a cross-sectional analysis of de-identified physician satisfaction surveys for US health plans in 2016. We included the following satisfaction domains that were rated by physicians on 5-point Likert scales as key outcomes of interest: overall health plan rating; financial issues; utilization and quality management; network/coordination of care; pharmacy issues; call center experience; provider relations; and recommendation of the sponsor plan to other physicians' practices. We assessed the association between the following characteristics and outcomes of interest using multivariable linear regression, weighted by the number of respondents: vertical (payer-provider) integration status, health plan size, practice size, provider type, and years of practice.

RESULTS: We analyzed surveys from 3,158 physicians on 74 health plans. We observed highest satisfaction in overall plan rating, finance, and call center domains (adjusted means 3.25), and lowest satisfaction in pharmacy (adjusted mean 3.02). The largest and smallest plans and vertically integrated plans had the highest satisfaction: 76% of physicians recommended vertically integrated plans while 66% of physicians recommended non-vertically integrated plans to others ($p<0.001$). Solo practitioners rated overall plan rating, finance, utilization/quality management and pharmacy domains more favorably than physicians in larger practices ($p<0.001$), while primary care physicians rated overall plan rating, finance, and utilization/quality management more favorably than specialists ($p<0.001$).

CONCLUSIONS: Our findings demonstrate that there is significant opportunity to improve physician satisfaction with health plans in all satisfaction domains, especially in pharmacy/formulary management. Since provider satisfaction is becoming increasingly recognized as a critical outcome, our findings suggest that health plans have a unique and important opportunity to improve physician satisfaction and highlight potential interventions such as prioritizing provider relationships, optimizing formulary management, reducing administrative burden, and providing resource support. Additionally, interventions could specifically target physicians in larger practices and non-vertically integrated and mid-size health plans. As physicians are required to adapt to a rapidly transforming healthcare landscape, it will be imperative for health plans to prioritize physician satisfaction moving forward.

PHYSICIAN-PHARMACIST COLLABORATIVE CARE MODELS TO PREVENT OPIOID MISUSE: A PILOT STUDY

Pooja A. Lagisetty¹; Alex Smith¹; Suzanne Winters¹; Michael A. Smith¹; Hae Mi Choe¹; Amy Bohnert¹; Michele Heisler². ¹University of Michigan, Ann Arbor, MI; ²Ann Arbor VA/University of Michigan, Ann Arbor, MI. (Control ID #3184050)

BACKGROUND: Clinical pharmacists embedded within primary care

clinics have the potential to help manage medications used to treat chronic pain and opioid use disorders (OUD). However, their current scope of practice mainly consists of managing diseases such as diabetes and hypertension. Therefore, we sought to pilot and evaluate the feasibility and acceptability of a physician-pharmacist collaborative care model to assist with chronic pain and OUD management.

METHODS: The program consisted of an in-person pharmacist consultation as well as optional follow-up phone or in-person visits over a 4-month period in 2 large academic primary care practices. Eligible patients had chronic pain + a long-term prescription for opioids or for buprenorphine. The pharmacist reviewed participants' past pharmacologic and non-pharmacologic treatments and discussed the risks and benefits of the current medication regimen and potential alternatives. Recommendations were communicated back to the PCP via the electronic health record (EHR). Due to controlled substance regulations, the pharmacist did not have any prescriptive authority. We used mixed-methods to evaluate the model. These included baseline and follow up participant survey assessments on pain, co-morbid substance abuse disorders (SUDs), ED utilization, and naloxone and buprenorphine knowledge; EHR review of number of phone calls and clinic visits focused on opioids; and semi-structured interviews with 8 providers (7 MD and 1 PharmD) to assess feasibility and acceptability.

RESULTS: Between January and October 2018, 47 of the 182 patients who met eligibility criteria enrolled in the intervention, and 46 completed all follow-up assessments. Mean age was 55.8 yrs (SD=11.9), and 55% were women. 43 (91%) of patients had received opioids over the past 6 months. The pharmacist recommended tapering opioids to 3 (6%) of patients, adding or changing to a non-opioid pain medication to 30 (64%) patients, and switching to buprenorphine for pain management in 20 (43%) of patients. The number of patient calls and visits related to pain decreased from 10.4 during the 4 months prior to the initial pharmacist visit to 8.9 in the 4 months after that visit ($p=0.059$). Physicians found the intervention acceptable but wanted more guidance and support on using buprenorphine for pain. Patients felt that the in-depth conversations were helpful, but some reported lack of physician follow up to recommended medication changes.

CONCLUSIONS: This study demonstrated that using clinical pharmacists for patients with chronic pain and OUD management is feasible, acceptable, and shows promise in decreasing healthcare utilization related to opioid management. Policy changes to increase pharmacist prescriptive authority to co-manage controlled substances may increase physician willingness and confidence to carry out opioid tapers and prescribe buprenorphine.

POINT-OF-CARE MOBILE APPLICATION TO GUIDE HEALTH PROFESSIONALS IN CONDUCTING SUBSTANCE USE SCREENING AND INTERVENTION: A MIXED-METHODS USER EXPERIENCE STUDY

Sandeep Kapoor^{1,2}; Megan O'Grady³; Evan Gilmer³; Charles J. Neighbors³; Nancy Kwon^{4,2}; Joseph Conigliaro^{1,2}; Jonathan Morgenstern^{5,2}. ¹Northwell Health, New Hyde Park, NY; ²Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; ³National Center on Addiction and Substance Abuse, New York, NY; ⁴Northwell Health - Long Island Jewish Hospital, New Hyde Park, NY; ⁵Northwell Health, Great Neck, NY. (Control ID #3186087)

BACKGROUND: Well-documented barriers have limited the widespread, sustained adoption of screening and intervention for substance use problems in healthcare settings. Mobile health (mHealth) applications may address provider-related barriers; however, there is limited research on development and user experience of such applications. Despite being a major public health issue, substance use remains under addressed in healthcare settings. A 2017 report indicates only one in six binge drinkers in the US are asked about alcohol use and advised to cut down by a health professional. Screening, Brief Intervention, and Referral to Treatment (SBIRT) is a model that can be used in healthcare settings to identify and address risky substance use. Evidence for SBIRT efficacy has been demonstrated with the strongest evidence coming from studies conducted in *primary care* that target reductions in alcohol use.

Better patient outcomes may be achieved by combining technology-based programs with in-person provider intervention. Several studies have shown that computer-guided, provider-delivered substance use interventions have equivalent or even better outcomes than patient self-administered computerized programs. However, most technology-based SBIRT programs described in the literature are patient self-administered and do not directly involve a healthcare provider. Therefore, because providers are an important piece of the puzzle from a clinical and technology adoption standpoint, their input on user experience is essential to the production of clinically relevant provider-focused mHealth SBIRT technology.

METHODS: The SBIRT app was designed for use by providers in conjunction with patients during a healthcare visit to assist the provider in assessing the patient's level of risk due to substances use and walk them through the steps of a brief intervention that is tailored to the patient's responses. This mixed methods study included think-aloud tasks, task-success ratings, semi-structured interviews, and usability questionnaires (e.g., System Usability Scale [SUS]) to examine user experience among 12 health coaches who provide substance use services in emergency department and primary care settings.

RESULTS: The average rate of successful task completion was 94% and the mean SUS score was 76 out of 100. Qualitative data suggested the app enhanced participants' capability to complete tasks efficiently and effectively. Participants reported satisfaction with the app's features, content, screen layout, and navigation and felt it was easy to learn, and could benefit patient interactions.

CONCLUSIONS: Overall results indicate acceptable user experience and usability for this provider-focused point-of-care mobile app for substance use screening and intervention as well as favorable potential for adoption by healthcare practitioners. Such mobile health technologies may help to address well-known challenges related to implementing substance use services in healthcare settings.

POLYPHARMACY: PATIENT AND PHYSICIAN CONTRIBUTION

Niyati M. Gupta¹; Bo Hu¹; Luke D. Kim²; Simon W. Lam²; Giavanna Russo-Alvarez²; Michael B. Rothberg². ¹Cleveland Clinic Foundation, Cleveland, OH; ²Cleveland Clinic, Cleveland, OH. (Control ID #3180369)

BACKGROUND: Polypharmacy is common among older patients. It is associated with more primary care visits, drug-drug interactions, fall-related hospitalizations and mortality. Our objective was to study the burden of polypharmacy in an elderly population and identify patient factors associated with it, as well as assess the variation in individual provider's rates of polypharmacy.

METHODS: We conducted a retrospective cohort study of patients aged 65 years who had an ambulatory visit to an internal medicine or family medicine provider in 2015. For each patient, we extracted the following factors: demographics, comorbidities, medications (name, order date, sig and refills), and specialty visits; and details about their primary care provider (PCP). Pearson's chi-square tests were used to assess the association between polypharmacy and each patient factor. We then used linear regression to assess the association between patient factors and total medications. Using our regression model, we compared PCPs' adjusted rates of medication prescribing.

RESULTS: Our sample included 51,093 patients cared for by 681 physicians. Patients' mean age was 75.3 years, 59% were male, 84% were white, 33% had a BMI of 30 kg/m²; and 47% were former smokers. Patients took an average of 7.9 medications (median 7, IQR 5 to 10): 24% patients took <5, 45% took 5-9, 31% took 10 medications. Compared to patients taking <10 medications, those taking 10 medications were older (76 vs. 75 years), more often male (61% vs. 58%), Black (16% vs. 11%), not married (44% vs. 35%), obese (47% vs. 34%), and had more comorbidities (8 vs. 4), specialists (9 vs. 5) and specialty visits (39 vs. 15 visits in the past 2 years). (p<0.001 for all comparisons) The following factors

were independently associated with number of medications: age (= 0.10 for age 86-90 years; 0.20 for >90 years), BMI (= 1.2 and 1.56 for BMI 35-39.9 and 40 kg/m² respectively), and Medicaid insurance (= 1.82). Organ transplant, cardiac and pulmonary conditions were the comorbidities most strongly associated with polypharmacy (= 2.0, 1.9 and 1.6 respectively). Of the observed variance in number of medications, demographics accounted for 2%, insurance status for 0.6% and co-morbidities for 33%. Adjusted mean medications prescribed by physician ranged from 6.5 to 11.4 (median 8.3, IQR 7.7 to 8.9). Overall, 18% of providers had adjusted prescribing rates significantly higher and 17% had rates significantly lower than the mean.

CONCLUSIONS: Polypharmacy is common in primary care; 31% patients took 10 medications. Co-morbidities explain only 33% of the variance in number of medications, and there was extreme variation in physician prescribing rate that could not be explained by patient factors. More study is needed to understand physician attitudes that lead to polypharmacy in the elderly.

POST-DISCHARGE PATIENT-REPORTED DATA ON PAIN, APPETITE, HEART FAILURE SYMPTOMS AND MANAGEMENT AS PREDICTORS OF READMISSION OR ED VISITS

Jinying Chen¹; Rajani Sadasivam¹; Amanda C. Blok^{3, 1}; Christine Ritchie²; Catherine S. Nagawa¹; Elizabeth Orvek¹; Kanan Patel²; Thomas Houston¹. ¹University of Massachusetts Medical School, Worcester, MA; ²University of California San Francisco, San Francisco, CA; ³Bedford VA Medical Center, Bedford, MA. (Control ID #3185384)

BACKGROUND: After a hospital discharge, patients with heart failure have higher rates of early repeat acute care use (i.e.: readmission or emergency department (ED) use within 30 days) than other patients. Current efforts on predicting risk of repeat acute care utilization rely on inpatient data from electronic health records. However, many changes occur after the transition to home. Post-discharge patient-generated data relevant to care transitions has had limited exploration. We examine the association between post-discharge patient-generated data and early repeat use of acute care.

METHODS: We used data from 156 patients with index hospitalization for chronic heart failure from a large tertiary hospital. For the first seven days after discharge, using a daily interactive voice response automated phone call to the home of the patient, we collected patient-reported health status, heart failure symptoms (dyspnea and edema), medication management, knowledge of healthcare follow-up plans, and other issues like pain and poor appetite. These patient-reported data from automated calls was reviewed by care transition nurses to determine whether a management call was required. Patients were also followed for 30 days after discharge to assess repeat acute care utilization. We examined the association between each patient-reported predictor variable and the 30-day outcome by using multivariable logistic regression, adjusting for race, marital status, disease burden, and also participation (number of automated phone calls completed) and the number of transition nurse's management calls.

RESULTS: Patients were on average 63 years old; 51% were African-American, 52% were women, and 18% had less than high school education. Most patients (147 (94.2%)) responded to all the automated phone surveys. At the end of 30-days post discharge, 30 (19%) patients had again used acute care. After adjustment, patient-reported dyspnea, edema, medication management issues, and lack of understanding of follow-up were not associated with early acute care use. Overall health status (OR: 3.5; 95% CI: 1.1, 11.6), pain (OR: 2.6; 95% CI: 1.1, 6.2), or poor appetite (OR: 2.8; 95% CI: 1.1, 7.4) were positively associated with 30-day acute care utilization. Among 58 reports of pain in follow-up nursing notes, 2 (3%) were cardiac pain, 39 (67%) were non-cardiac pain (e.g.: leg pain, abdominal pain, knee pain, back/hip pain and headache), and 17 (29%) with undetermined sources.

CONCLUSIONS: Patient-reported poor health status, pain (frequently non-cardiac), and poor appetite were positively associated with 30-day acute care utilization, and surprisingly, associations were stronger for these

patient-reported data than for the common heart failure warning signs. These novel post-discharge markers require further study and consideration for incorporation into risk prediction to drive quality improvement efforts.

POST-DISCHARGE RESOURCE USE AND 30-DAY UNPLANNED HOSPITAL READMISSIONS IN PATIENTS ADMITTED FOR HEART FAILURE

Molly J. Horstman^{1, 2}; Javad Razjouyan¹; Jacqueline Shahin²; Aanand D. Naik^{3, 2}. ¹Michael E. DeBakey VA Medical Center, Houston, TX; ²Baylor College of Medicine, Houston, TX; ³Michael E. DeBakey VAMC, Houston, TX. (Control ID #3186013)

BACKGROUND: Patients have the opportunity to interact with the healthcare system following discharge using a range of communication methods. This study seeks to examine the role of different types of post-discharge encounters on unplanned hospital readmissions in patients with an index admission for congestive heart failure.

METHODS: This is a retrospective cohort study using a national Veterans Health Administration dataset of patients admitted with a principal diagnosis of congestive heart failure from 2012 to 2014. The outcome of interest was unplanned readmissions within 30 days of hospital discharge. The independent variables were post-discharge outpatient encounters up to 30 days following hospital discharge: primary care appointments, phone calls with primary care, phone calls with a 24-hour triage nurse, phone calls with a telemonitoring nurse, and cardiology appointments. Post-discharge outpatient encounters were recorded as being absent or present following discharge (dichotomous variable). For patients with a readmission, only encounters occurring between discharge from the index admission and the readmission were recorded. We used multivariable logistic regressions to determine the impact of post-discharge outpatient encounters on unplanned 30-day readmissions while controlling for age, race/ethnicity, Charlson/Deyo comorbidity index, length of hospital admission, and number of admissions in the 12 months prior to the index admission.

RESULTS: There were 36,903 index admissions that met the inclusion criteria. The unadjusted, unplanned 30-day readmission rate was 19.2%. Veterans with a readmission were older (71.8 (11.5) vs. 72.4 (11.2), p<0.027) and had more comorbidities (Charlson/Deyo Comorbidity Index, 2.2 (2.1) vs. 2.7 (2.2), p<0.001). Post-discharge encounters between patients and the primary care team were common (non-readmitted patients: 75.9% (n=22,615) had at least one phone call with primary care, 62.4% (n=18,592) had at least one primary care appointment; readmitted patients: 71.5% (n=5078) had at least one phone call with primary care, 42.0% (n=2,984) had at least one primary care appointment). The odds of an unplanned 30-day readmission were lower for Veterans with a primary care appointment following discharge (Adjusted OR 0.44, CI 0.41-0.46), a cardiology appointment (Adjusted OR 0.50, CI 0.47-0.53), a phone call with a telemonitoring nurse (Adjusted OR 0.64, CI 0.59-0.69), or a phone call with primary care (Adjusted OR 0.77, CI 0.73-0.82). The odds of an unplanned readmission were higher for Veterans who had an ER visit (Adjusted OR 30.60, CI 28.6-32.9) or phone call with a 24-hour triage nurse (Adjusted OR 1.17, CI 1.09-1.25).

CONCLUSIONS: Patients who are readmitted to the hospital use healthcare system resources differently than patients who are not readmitted. Learning Healthcare Systems may be able to use post-discharge outpatient encounters to identify patients at risk for hospital readmission.

POTENTIAL FOR UNINTENDED CONSEQUENCES: THE ASSOCIATION BETWEEN SMOKING AND BODY MASS INDEX AMONG PUBLIC HOUSING RESIDENTS IN BALTIMORE, MARYLAND

Alejandra Ellison-Barnes¹; Craig E. Pollack²; Jeanne M. Clark¹; Kimberly Gudzune¹. ¹Johns Hopkins University, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3185870)

BACKGROUND: The newly implemented U.S. Department of Housing

and Urban Development (HUD) rule requiring public housing to be smokefree may prompt some smokers to quit. While smoking cessation is generally desirable, it is associated with weight gain, and an excess burden of obesity already exists among public housing residents. Given little previous research on smoking and weight status in this population, our objective was to characterize the baseline association prior to the policy implementation.

METHODS: We conducted a cross-sectional analysis of survey data collected in 2014-2015 from randomly selected households of two public housing developments in Baltimore, MD (response rate 48%). Our independent variable was self-reported smoking status (current vs. former/never), and the dependent variable was measured body mass index (BMI). We used multivariate linear regression to examine the association between smoking status and BMI, adjusting for age, gender, physical activity level, added sugar intake, and housing development.

RESULTS: Respondents included 266 heads of household with mean age 44.5 (SD 12.4). Of these, 86% were women and 95% were Black. A majority (63.2%) were current smokers. Seventy-five percent were overweight or obese, with unadjusted mean BMI of 32.6kg/m² (SD 10.1). In the adjusted regression model, the mean BMI of current smokers was significantly lower than that of former/never smokers at 34.9kg/m² versus 37.4kg/m² (-2.6kg/m², 95% CI -5.0 to -0.07, p=0.044).

CONCLUSIONS: Among Baltimore public housing residents, the adjusted mean BMI of current smokers was significantly lower than that of former/never smokers after controlling for other risk factors, however it was still in the class I obesity range. Notably, nearly two-thirds of residents were current smokers and three-quarters were overweight or obese. Our results suggest that the new HUD smokefree rule has the potential to promote further weight gain that might lead to a higher risk class of obesity among smokers prompted to quit, highlighting the need to consider both of these prevalent risk factors in tandem in the setting of policy changes.

POTENTIAL IMPACT OF CHANGING PUBLIC CHARGE IMMIGRATION RULES ON CHILDREN WHO NEED MEDICAL CARE

Leah Zallman^{1, 3}; Karen Finnegan¹; David Himmelstein^{2, 3}; Stephanie Woolhandler^{2, 3}. ¹Institute for Community Health, Malden, MA; ²City University of New York at Hunter College, New York, NY; ³Cambridge Health Alliance/Harvard Medical School, Cambridge, MA. (Control ID #3184560)

BACKGROUND: In October, 2018, the Trump administration published a proposed rule change that would increase the chance of an immigrant being deemed a "public charge" and hence ineligible for legal permanent resident status or entry into the US. Under existing immigration policy, only immigrants who receive cash assistance or are institutionalized are considered to be "public charge". If these changes are finalized, immigrants' use of non-emergency Medicaid, Supplemental Nutrition Assistance Program, housing assistance and Medicare Part D low-income subsidy will be used to determine if they are "public charges". This change is expected to cause large numbers of immigrant parents to disenroll themselves and their children from safety-net programs, in large part due to fear and confusion over the rule even among immigrants to whom the rule does not apply.

METHODS: We analyzed a nationally representative sample from the 2015 Medical Expenditure Panel Survey. We estimated the number children "in need of medical care" who are at risk of disenrolling from Medicaid/CHIP and compared them with Medicaid/CHIP-enrolled children who were not at risk. We include CHIP because many states use blended funding for Medicaid and CHIP, and Medicaid and CHIP beneficiaries often do not know which program is funding their health coverage. We defined "at risk of being disenrolled" as living in a household with any non-citizen adult, whether or not the child was a U.S. citizen. We defined children as being "in need of medical care" if they 1) were diagnosed with a medical condition such as asthma; 2) were disabled (functionally limited or disabled due to mental health condition); or 3) had used care in the 12 months (were prescribed medications, received care for illness or injury, or received any

care, test or treatment). Finally, we modelled the number of children who would be disenrolled from Medicaid/CHIP under disenrollment scenarios similar to what occurred during welfare reform.

RESULTS: Medicaid/CHIP-enrolled children are at risk of being disenrolled due to public charge rule changes. 4.8 million of these children are "in need of medical care". Consistent with other data showing that immigrant families tend to be relatively healthy, children at risk of being disenrolled are somewhat healthier than other Medicaid/CHIP-enrolled children; they are less likely to have medical conditions (48.7 vs. 62.8%, $p < 0.0001$), to be disabled (6.6 vs. 16.8 %, $p < 0.0001$) or to have used care in the past year (40.5 vs. 50.8%, $p < 0.0001$). Our models predict that between 0.7 and 1.7 million children in "need of medical care" will likely be disenrolled from Medicaid/CHIP if the new public charge rules are implemented.

CONCLUSIONS: The proposed public charge rules may cause many children "in need of medical care" to be disenrolled from Medicaid/CHIP. The loss of insurance coverage could harm these children and contribute to future disability.

PRECISION MEDICINE IN PRIMARY CARE: AN EVALUATION OF INTEGRATION OF PERSONALIZED DATA AND SERVICES INTO PRIMARY CARE TO REACH HEALTH EQUITY

Nadia Safaeinili¹; Cati Brown-Johnson²; Lisa Goldman Rosas³; Latha Palaniappan¹; Marcy Winget⁴; Megan Mahoney³. ¹Stanford University, Stanford, CA; ²Stanford School of Medicine, Stanford, CA; ³Stanford University, Palo Alto, CA; ⁴Stanford University Medical School, Stanford, CA. (Control ID #3185585)

BACKGROUND: Precision medicine takes into account the complex interplay between genes, environment, and lifestyle by leveraging clinical, self-reported, genetic, and behavioral data to offer targeted approaches to prevention and treatment. Patient and provider attitudes toward implementation in primary care, however, are unknown.

METHODS: Primary care patients were enrolled in a precision health pilot and offered digital health (remote blood pressure, glucose, and weight monitoring with electronic health record integration), health coaching, pharmacogenetic, and genetic testing components. To evaluate the pilot, we summarized patient demographics, health status, and health outcomes using means and frequencies. Semi-structured interviews were conducted with patients and providers at baseline ($n=18$ and 7, respectively) and 6 months ($n=9$ and 6, respectively).

RESULTS: Of 67 patients invited to participate, 48 enrolled (72%). Patients were diverse (4% Black 27% Asian, 19% Latino); female (67%); and with complex health needs (58% cardiovascular (CV) risk, mean body mass index (BMI) 31 kg/m²). Patients reported mixed clinical benefit from precision health, though most felt participation supported their health goals and impacted their health and healthcare. Patient suggestions for improvement included fewer in-person clinical visits and the ability to select resources based on individual motivators. Providers reported that precision health resources were valuable, especially for complex patients, but sometimes resulted in misplaced emphasis on novelty rather than basics. The complexity of some resources also presented barriers, e.g., lengthy genetics test results and management of extensive digital health data. Interviewees identified three barriers to dissemination of precision health in primary care to address health disparities. First, the lack of racial/ethnic minority representation in genomics databases was perceived to reduce impact for those groups. Second, patients would need significant financial resources to participate outside a pilot, potentially exacerbating disparities for patients from low-income backgrounds. Third, providers struggled to incorporate precision medicine components into their work flow; these struggles may be magnified in safety net settings with fewer resources.

Overall, precision health was appealing to patients and providers. Workflow integration, however, slowed initial pilot adoption. Both providers and patients felt precision health would be difficult to scale due to cost and uncertain processes for data utilization.

CONCLUSIONS: Introducing precision health into a diverse primary care clinic was acceptable to all stakeholders and did not surface many concerns related to race/ethnicity. Furthermore, nearly half of the pilot's patients experienced a clinically-relevant finding that changed their treatment plan. Barriers and facilitators surfaced here should be addressed in future precision health interventions.

PREDICTING FUTURE DISPARITIES FOR BLACK AND WHITE US ADULTS LIVING WITH TYPE 2 DIABETES

Abena Appah-Sampson; Neda Laiteerapong. University of Chicago, Chicago, IL. (Control ID #3179193)

BACKGROUND: Historically, Black patients living with Type 2 diabetes have had a higher risk for diabetes complications compared to White patients. However, control of individualized glycemic targets, blood pressure, and lipid levels have improved in the U.S. for patients living with Type 2 diabetes over the past decade. Therefore, we compared projected disparities in lifetime diabetes outcomes between two cohorts of Black and White US adults living with Type 2 diabetes.

METHODS: Survey Population: Non-Hispanic Black (NHB) and Non-Hispanic White (NHW) adults with self-reported diabetes diagnosed at <18 years old included in NHANES 2003-2004 (NHB: n=97; NHW: n=183) and in NHANES 2013-2014 (NHB: n=164; NHW: n=224). Simulation model: The U.S. Type 2 Diabetes Policy Model (UST2D-PM) is a validated, Monte Carlo-based Markov model. The model utilizes individual patient-level information to forecast diabetes complications and risk of diabetes-related mortality. Outcomes: Lifetime risk of foot ulcer, blindness, renal failure, amputation, myocardial infarction, ischemic heart disease, and stroke; remaining life expectancy, by cohort year and race/ethnicity (NHB and NHW). Statistical Analysis: A multiple imputation procedure was utilized to address missing data. Model outcomes were weighted using NHANES survey weights. Results were compared by cohort year and by racial/ethnic subgroup using regression models.

RESULTS: There were not significant improvements in projected lifetime rates of diabetes outcomes overall or between racial subgroups between the 2003 and 2013 cohorts. The projected lifetime rate of amputation for the overall cohort was higher for the 2013 cohort compared to the 2003 cohort (6.2% vs. 5.5%, $p=0.02$), which reflected a higher projected lifetime rate of amputation for the 2013 NHW cohort vs the 2003 NHW cohort (6.2% vs. 5.3%, $p=.01$). Also, the projected lifetime rate of renal failure was higher for the 2013 cohort than the 2003 cohort (8.0% vs 5.7%, $p = .04$), which was driven by a 60.6% higher event rate for 2013 NHBs (9.3%) compared to 2003 NHBs (3.7%, $p=.01$). This result was due to a longer average duration of diabetes in the 2013 NHB cohort compared to the 2003 NHB cohort (9.4 vs. 12.3 years, $p=.03$).

CONCLUSIONS: Despite large scale efforts to reduce diabetes health disparities, our study suggests that racial disparities in the rates of complications from diabetes progression may not decline in the future. Greater efforts to ensure that patients achieve guideline-recommended risk factor control and targeted efforts to improve control in non-Hispanic Black patients are necessary to reduce future disparities in diabetes outcomes.

PREDICTING LONG-TERM HEALTHCARE SPENDING THROUGH LONGITUDINAL MODELING IN MEDICARE PATIENTS

Julie Lauffenburger; Mufaddal Mahersi; Niteesh K. Choudhry. Brigham and Women's Hospital, Harvard Medical School, Boston, MA. (Control ID #3185020)

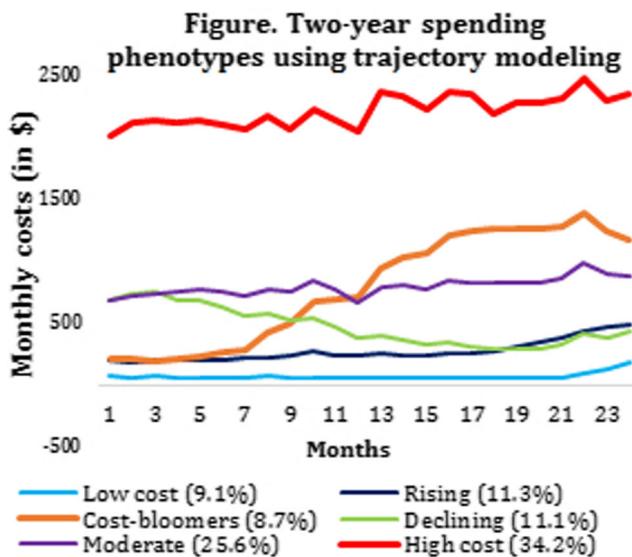

BACKGROUND: Current approaches to predicting healthcare costs

generally rely on a single composite value of total spending and have modest predictive accuracy. Newer approaches that incorporate dynamic patterns of spending could improve accuracy and therefore cost-containment efforts by healthcare organizations. We recently showed that using group-based trajectory modeling enhanced the prediction of costly patients over a one-year time horizon; however, less is known about longer-term spending dynamics and potentially-modifiable risk factors for patient intervention.

METHODS: We used group-based trajectory modeling to empirically classify a random nationwide sample of Medicare beneficiaries 65 years enrolled by their spending patterns over a two-year period. We then assessed the ability to predict membership in each trajectory group using logistic regression and split-sample validation. Models were estimated using 1) baseline clinical and demographic factors and 2) only baseline factors that are potentially-modifiable through interventions.

RESULTS: In 329,476 patients, a 6-group trajectory model best described two-year longitudinal spending patterns (Figure), including high-cost (in red) and cost-bloomer (in orange) groups. Four spending groups could be highly predicted, including high-cost (validated C-statistic [C]: 0.887), cost-bloomers (i.e., lower spendings who later became more costly) (C: 0.722), rising (C: 0.810), and low-cost (C: 0.953). For cost-bloomers in particular, the most predictive potentially-modifiable factors were patients' number of medications, number of hospitalizations, and depression.

CONCLUSIONS: Examining a two-year time horizon using trajectory modeling improved the understanding of dynamic patterns, including the identification of a group of cost-bloomers and patients who are consistently high spenders. This approach could be adapted and implemented by healthcare organizations to improve cost-containment efforts.

PREDICTING UNMET VA PRIMARY CARE NEED USING ECONOMIC DISEQUILIBRIUM MODELS

Edwin Wong¹; Christopher Wilson¹; Karin M. Nelson^{1, 2}. ¹Department of Veterans Affairs, Seattle, WA; ²University of Washington, Seattle, WA. (Control ID #3184178)

BACKGROUND: One of the key goals of the Patient-Centered Medical Home model is to improve access by providing care where and when patients need it. Recent reports have identified inadequate internal capacity as a key access barrier. There is currently limited evidence using rigorous methods to measure how much additional capacity is needed to meet veterans' health

care needs. The objective of this study was to jointly estimate the supply and demand of VA primary care visits using econometric disequilibrium models to quantitatively estimate unmet primary care demand.

METHODS: This observational study examined a random sample of 51 VA medical centers across the U.S. Data were derived from VA administrative databases, linked with geographically aggregated data from the Area Health Resource File and the Centers for Disease Control and Prevention over the period January 2014 through September 2018. The outcome was primary care utilization defined as visits at VA clinic locations identified to provide primary care. We modeled the supply of VA primary care as a function facility-level primary care staffing, local area characteristics and seasonality. We modeled the demand of VA primary care as a function of patient enrollment, demographics and risk scores, a geographically varying measure of flu severity and seasonality. Many VA patients are exempt from copayments or other cost sharing, therefore we applied econometric disequilibrium models [Madalla and Nelson (1974)] to estimate the magnitude of excess primary care demand. These models jointly estimate parameters of the supply and demand equations, addressing the fact that observed number of primary care visits does not represent quantity demanded by veterans when excess demand exists. Joint supply and demand models were estimated separately for each facility using a maximum likelihood estimator and the unit of analysis was facility-month.

RESULTS: The average number of primary care visits per month provided by VA facilities decreased from 3,104 (SD=1,750) to 2,654 (SD=1,557) between January 2014 and January 2018. For 34 facilities, we did not reject the null hypothesis that the estimated number of visits demanded equaled visits supplied. For 8 facilities, the estimated number of visits demanded exceeded visits supplied by an average of 32%. For the remaining 9 facilities, estimated visits demanded was less than visits supplied by an average of 22%.

CONCLUSIONS: The estimated quantities of primary care supplied and demanded were balanced at most facilities. However, model estimates suggest the level of primary care needed by veterans exceeded resources at some facilities, while at other facilities, staffing likely exceeded veterans' primary care needs. Study findings inform the level of primary care staffing needed by facilities to fully meet expected primary care demand of VA patients. Models in this study also provide the opportunity to forecast staffing needs as conditions change over time.

PREDICTORS AND FOLLOW-UP USING THE CURRENT OPIOID MISUSE MEASURE IN PRIMARY CARE

Mathew Tsai^{1, 2}; MacLean D. Charles^{1, 2}. ¹Larner College of Medicine, Burlington, VT; ²University of Vermont, Burlington, VT. (Control ID #3178274)

BACKGROUND: Misuse of prescription opioids is a growing public health issue associated with adverse health outcomes. Clinical guidelines recommend formal risk assessment tools such as the Current Opioid Misuse Measure (COMM), a validated 17 question self-report survey assessing prior 30-day behavior associated with concurrent opioid misuse. However, little is known about the COMM's clinical utility among clinicians or the predictors of a high COMM score. To address these uncertainties, this study aimed to describe the consistency of use of the COMM and the distribution of COMM responses in a primary care population; to identify sociodemographic and clinical predictors of a positive COMM score; and to explore the association between a positive COMM score and increased clinical surveillance for opioid misuse.

METHODS: We performed a cross-sectional analysis of data from

an academic medical center Epic-based clinical data warehouse. Institutional protocols, which follow CDC guidelines and State regulations require the annual use of consent and treatment agreements, risk stratification (e.g using the COMM), use of the prescription drug monitoring program (PDMP), and functional assessment. Study participants consisted of 859 adult patients on chronic opioid pain therapy who were not taking office-based opioid agonist treatment for substance abuse disorder and who had completed a COMM at an office visit during a three-year period from 1 January 2016 to 31 December 2018. The main outcome measure was the COMM score (positive if 9).

RESULTS: The mean COMM score was 4.2 (SD 4.5) and 13% of participants had a positive score. Additionally, 70% of the study population had a diagnosis of anxiety or depression and 50% were taking a concurrent gamma-aminobutyric acid (GABA) agonist. Regarding adherence to surveillance protocol, 21% of patients were overdue for a COMM. Patients were also overdue for an opioid patient consent form (32%), opioid treatment agreement (40%), PDMP lookup (17%), formal functional assessment (28%), a non-mandatory urine drug screen (32%), and pill count (64%). A multivariable model identified concurrent, weekly-or-greater use of GABA agonists ($OR=1.5$ 95% CI 1.0, 2.3, $p=0.04$) and severe mental illness ($OR=1.7$ 95% CI 1.0, 2.8, $p=0.04$) as significant predictors of a positive COMM score. No significant association was detected between COMM score and opioid surveillance measures.

CONCLUSIONS: The COMM is relatively easy to implement in primary care and is independently associated with severe mental illness and concomitant use of GABA agonist medication. However, the implications of a positive COMM score and the survey's clinical utility are still to be determined within these contexts.

PREDICTORS OF ELIGIBLE PATIENTS' AGREEING TO LUNG CANCER SCREENING WITH LOW-DOSE COMPUTED TOMOGRAPHY: A MULTILEVEL RETROSPECTIVE COHORT STUDY

Joseph Leishman⁴; Angie Fagerlin⁵; Julie Lowery²; Renda S. Wiener³; Tanner Caverly¹. ¹University of Michigan School of Medicine, Ann Arbor, MI; ²VA Ann Arbor Healthcare System, Ann Arbor, MI; ³Carolina Medical Center, UNC School of Medicine, Boston, MA; ⁴University of Michigan School of Public Health, Ann Arbor, MI; ⁵University of Utah School of Medicine, Salt Lake City, UT. (Control ID #3186294)

BACKGROUND: The clinical reminders used in VA's Lung Cancer Screening (LCS) Demonstration project offered a unique opportunity to examine real-world LCS decision-making. Since baseline lung cancer risk and comorbidity/competing risk are key factors in determining absolute risk reduction with LCS, we conducted a retrospective cohort study to assess the extent to which these key factors played roles in decisions compared with factors unrelated to clinical benefit.

METHODS: Across the 8 demonstration project sites, we identified all patients without health-related exclusions who met LCS eligibility criteria (>30 pack-years, < 15 years since quit and aged 55-80) and had an initial LCS reminder completed between 10/01/13-9/30/15. We then fit a multilevel mixed-effects logistic regression model to assess predictors of a patient agreeing to annual screening (based on reminder data), adjusting for site and patient demographics.

RESULTS: Our cohort included 6,037 patients (mean age 67; 96.5% male) who were considered appropriate candidates for LCS by their primary care providers and had documentation about whether they agreed to LCS after the initial provider discussion. The 2 variables related to net benefit (lung cancer risk and Charlson Comorbidity Index) were not associated with agreeing to screen, nor was gender. Two patient-level factors were significantly associated: age ($P<0.001$) and distance from the patients' listed home

address to the VA center offering LCS ($P=0.019$). For example, men at the cohort mean for other model covariates (mean annual lung cancer risk of 0.7%; Charlson score 1.12; and living 37.7 miles from the VA) were predicted to have a 78% probability of agreeing to screen at 57 years old but only a 60% probability at 77. Likewise, a 67-year-old-man with the same lung cancer risk and comorbidity score was predicted to have a 70% probability of agreeing to screen if living 37.7 miles from the VA but only a 34% probability if living 137.7 miles away. The site where LCS was offered only explained 8% of the overall variance in agreeing to screen (ICC=0.08), but this still resulted in substantial site-level variation ranging from a rate of 38% of eligible patients agreeing to LCS to a rate of 79% across the 8 sites.

CONCLUSIONS: Baseline lung cancer risk and level of comorbidity were not associated with whether a patient chose to pursue LCS, even though these factors largely determine a patient's degree of benefit. While variation in agreeing to screen based on patient age and distance from the VA might appropriately reflect differences in patient preferences, the large variation across sites likely reflects more about provider preferences than patient preferences. We are currently studying the implementation of a risk-based LCS provider tool that aims to help primary care providers and screening coordinators tailor screening discussions to a patient's individualized lung cancer risk.

PREDICTORS OF HEALTH INSURANCE LITERACY AMONG COMMUNITY HEALTH CENTER STAFF

Cory Williams^{1, 3}; Mellisa A. Pensa^{1, 2}; Douglas Olson¹. ¹Fair Haven Community Health Care, New Haven, CT; ²Yale University School of Medicine, New Haven, CT; ³AmeriCorps, New Haven, CT. (Control ID #3178362)

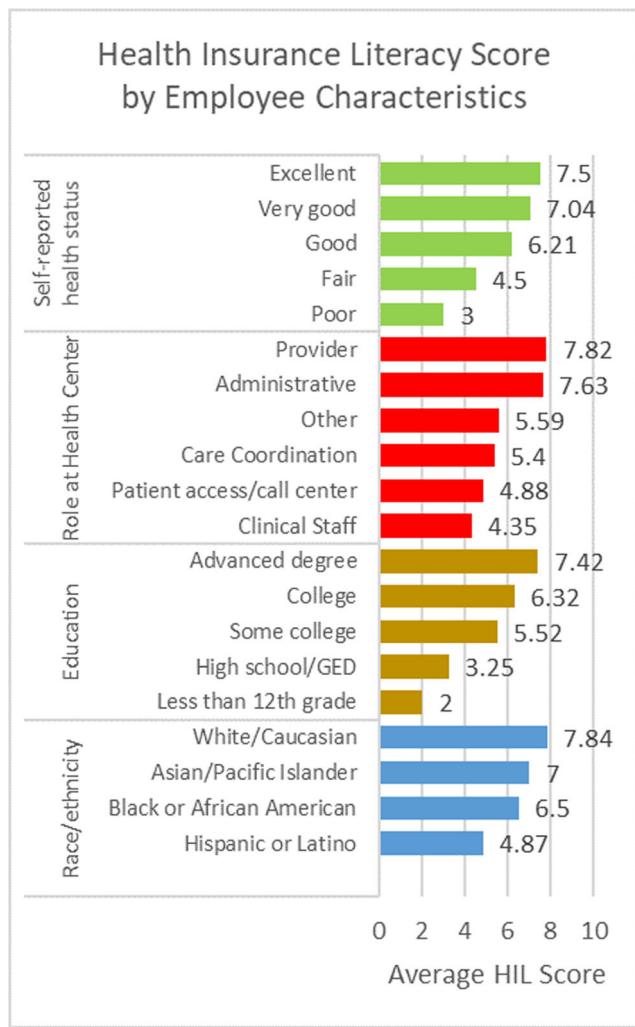

BACKGROUND: Despite increased attempts to make health insurance more accessible and comprehensive, low literacy and numeracy prevents many from understanding aspects of health insurance. Health Insurance Literacy (HIL) is the degree to which an individual is able to find and assess health insurance information and navigate health plans. Disparities in HIL are correlated with delayed access to care and poorer health status. The primary goal of this research is to measure HIL among staff at a Federally Qualified Health Center (FQHC) and identify predictors of knowledge gaps.

METHODS: This is a cross-sectional study assessing HIL among staff at Fair Haven Community Health Care (FHCHC), an urban FQHC in New Haven, CT. In November 2018, all 212 staff members were emailed an anonymous survey and 91 (43%) completed the survey, which was generated using Qualtrics™ software. Questions measured the participant's ability to identify and utilize various health insurance terms and topics. Descriptive statistics were calculated, and unadjusted analyses were used to examine potential associations between demographic, social, and health characteristics and HIL. We used Multivariate logistic regression to identify independent relationships to HIL. This study was approved by the FHCHC institutional review board.

RESULTS: Participants had a mean HIL score of 6.21 (out of 10), and characteristics that had a statistically significant difference in average score upon unadjusted analysis were race/ethnicity, education, role at FHCHC, and self-reported health status (Figure). Upon multivariate regression, education and job role remained significant predictors of HIL.

CONCLUSIONS: The majority of staff had gaps in HIL, and HIL is significantly associated with education, professional status, race/ethnicity, and self-reported health status. Results of this study will be used to target staff and community training efforts.

Average health insurance literacy score (HIL) is represented in the

bars and organized by employee characteristic.

PREDICTORS OF IATROGENIC HYPOGLYCEMIA IN TREATMENT OF HYPERKALEMIA

Anh Do¹; Sandra Naffouj¹; Krishna Modi¹; Rawan Hammoudeh¹; Joseph Miller¹; Mohammed F. Dabbagh². ¹Henry Ford Hospital, Detroit, MI; ²Henry Ford Hospital / Wayne State University, Detroit, MI. (Control ID #3185737)

BACKGROUND: Hypoglycemia is a potential adverse outcome that could complicate the treatment of hyperkalemia with insulin administration. Treatment needs to be individualized for patients' specific characteristics to avoid iatrogenic hypoglycemia. Our study aimed to identify characteristics that could increase the risk of hypoglycemia.

METHODS: A retrospective study at a large tertiary institution was conducted from December 2016 to November 2017. A chart review was performed on adult patients who received subcutaneous insulin and intravenous glucose for treatment of hyperkalemia (potassium > 5 mmol/L) while present in the emergency department or inpatient setting. Patients who received insulin for the treatment of hyperglycemia were excluded. Data including demographics, insulin dose, and laboratory values were collected. The cohort was divided into two groups; patients who developed hypoglycemic events (defined as serum glucose < 70 mg/

dL) and those who did not. Univariate and multivariate analysis was performed. The primary outcome was incidence of hypoglycemia. The secondary outcome was identifying predictors of hypoglycemia.

RESULTS: 1156 consecutive patients with hyperkalemia who were treated with insulin were analyzed. Mean age was 61 years, 59% were males, and 61% were African American. 69% had chronic kidney disease, and of those 32.7% were on hemodialysis. The mean dose of insulin administered was 0.105 + 0.05 units/kg for a median pre-treatment potassium level of 5.9 mmol/L. 17.8% of patients developed hypoglycemia (N=206). The median pre-treatment glucose level was 126 mg/dL, and mean hypoglycemia level was 53 mg/dL. On multivariate analysis age ($p=0.0328$), pre-treatment glucose level ($p<0.0001$), and insulin dosing ($p=0.0032$) were significant predictors of hypoglycemia. For every 10-year increase in age, the risk of hypoglycemia increased by an odds ratio (OR) of 1.128. For every 10 mg/dL increase in the pre-treatment glucose level, the odds of developing hypoglycemia were reduced by an OR of 0.929. For every 0.025 units/kg increase of insulin dosing above the 0.1 units/kg usually administered, the OR for hypoglycemia was increased by 1.006. There was a significant difference in the rates of hypoglycemic events between the emergency department (24.2%) compared to the general practice units (18.4%) and intensive care units (12.8%) ($p<0.001$). There was no relationship between insulin dose and pre-treatment glucose ($R^2 = 0.0006$).

CONCLUSIONS: Patients with older age, lower pre-treatment glucose, and higher insulin doses were at increased risk of developing hypoglycemia following treatment of hyperkalemia with insulin. Clinicians should more regularly evaluate baseline glucose levels when treating hyperkalemia with insulin to prevent iatrogenic hypoglycemia.

PREDICTORS OF LONG-TERM HIGH HEALTHCARE UTILIZATION AMONG NEW MEDICAID ENROLLEES

Somalee Banerjee¹; Amy Alabaster³; Patricia Kipnis⁴; Alyce S. Adams². ¹Kaiser Permanente Oakland, Oakland, CA; ²Kaiser Permanente, Oakland, CA; ³Kaiser Permanente Northern California, Oakland, CA; ⁴Kaiser Health Plan, Oakland, CA. (Control ID #3183708)

BACKGROUND: The 2014 Medicaid expansion with the Affordable Care Act (ACA) increased access to healthcare for underserved patients, but also increased cost. Interventions centering on care coordination for the highest healthcare utilizers or "super-utilizers" have not been effective in reducing cost because utilization typically normalizes over a year. There is limited knowledge about predictors of long-term utilization after a year. Identifying these predictors can help target populations most likely to benefit from case management and support. This study analyzes the association of diagnoses made at enrollment with the odds of super utilization and long-term super-utilization over the first two years in a cohort of newly enrolled Medicaid patients in a large integrated care system.

METHODS: This retrospective cohort study used electronic health record (EHR) data from Kaiser Permanente Northern California for 28,653 adults newly enrolled in Medicaid managed care between June and December 2014. The super-utilizer subgroup were patients in the top 5th percentile of total healthcare cost. Differences in baseline characteristics of super-utilizers and non-super-utilizers were determined using bivariate analysis. Multivariable logistic regression determined the independent association between super-utilization in the first year (model 1) or super-utilization in the second year of enrollment (model 2) and comorbidities: mental health conditions (anxiety, depression, bipolar disorder or schizophrenia), substance use, cancer, BMI and other chronic diseases (Charlson comorbidity index greater than 2). Each model was adjusted for age, gender, race, English as first language, socioeconomic characteristics, dual enrollment, physician visits, and months enrolled.

RESULTS: More super-utilizers (1,428) had chronic mental and physical health conditions than the non-super-utilizer (27,080) Medicaid population. Patients with the following comorbidities at enrollment had significantly increased odds of being super-utilizers over their first year of Medicaid enrollment after controlling for socio-demographics and enrollment: any

mental health condition, chronic pain, active cancer, high Charlson comorbidity score, alcohol use disorder, and drug use disorder (Figure 1a). Among first-year super-utilizers, chronic pain, 2+ Charlson comorbidities, and schizophrenia were associated with second year super-utilization in adjusted models (Figure 1b).

CONCLUSIONS: Diagnoses of mental health conditions, substance use and other comorbid medical conditions at enrollment for Medicaid patients can predict super-utilization over the first year. Among super-utilizers, only patients with schizophrenia, chronic pain and comorbid medical illness showed significantly increased odds of long-term super-utilization over the second year. Focusing similar interventions on super-utilizer patients with risk factors for long-term utilization identified in this study could lead to improved quality and decrease of avoidable utilization.

PREDICTORS OF MORTALITY IN PATIENTS TREATED WITH BUPRENORPHINE FOR OPIOID USE DISORDER

Danielle R. Fine; Yuchiao Chang; Virginia Triant; Travis P. Baggett; Joshua Metlay. Massachusetts General Hospital, Boston, MA. (Control ID #3179036)

BACKGROUND: Opioid replacement therapy (ORT) has been shown to reduce mortality in patients with opioid use disorder (OUD), yet mortality in those receiving ORT remains higher than in the general population. While several studies have evaluated risk factors associated with mortality in patients treated with methadone, there is limited research evaluating individuals treated with buprenorphine. The objective of this study was to identify risk factors for mortality in patients treated with buprenorphine for OUD.

METHODS: We conducted a retrospective cohort study utilizing a centralized clinical data registry within a multi-hospital health system in Boston, MA to identify adult (18 years) patients who were prescribed 2 consecutive buprenorphine prescriptions from January 1, 2007 to December 31, 2017. We abstracted baseline demographic, socioeconomic, and clinical characteristics from the clinical data registry. The primary outcome was all-cause mortality occurring by October 31, 2018. We identified deaths by linking the clinical data registry to both the National Death Index and the Massachusetts Registry of Vital Records and Statistics. We performed multivariable cox regression to identify baseline characteristics independently associated with all-cause mortality.

RESULTS: Of the 5,951 patients prescribed 2 consecutive buprenorphine prescriptions, the majority were white (80.7%), male (59.7%), with a mean age of 38.2 years at study entry. The all-cause mortality rate was 2.24 deaths per 100 person years. Baseline characteristics independently associated with an increased risk of all-cause mortality were: age (adjusted hazard ratio [aHR]=1.25 per ten years of age; 95% confidence interval [CI]=1.17, 1.33), male gender (aHR=1.34; 95% CI=1.12, 1.60), congestive heart failure (aHR=1.92; 95% CI=1.49, 2.47), pulmonary disease (aHR=1.23; 95% CI=1.02, 1.47), hepatitis C (aHR=1.60; 95% CI=1.28, 2.01), chronic kidney disease (aHR=2.12; 95% CI=1.17, 3.83), malignancy (aHR=1.31; 95% CI=1.03, 1.68), and a concurrent opioid prescription within 90 days of entering the study (aHR=1.28; 95% CI=1.07, 1.53). In addition, patients initially treated with buprenorphine as inpatients (vs. outpatients) had an independently increased risk of death (aHR=1.44; 95% CI=1.20, 1.74). Similarly, patients who entered the study from 2014-2015 (aHR=1.48; 95% CI=1.09, 2.01) and from 2016-2017 (aHR=1.70; 95% CI=1.20, 2.41) had an independently increased risk of death compared to those who entered from 2007-2009.

CONCLUSIONS: In a large cohort of patients with OUD treated with buprenorphine, older age, multiple medical comorbidities, a concurrent opioid prescription, and initial treatment as an inpatient were independently associated with mortality. Consistent with trends in national opioid-related deaths, mortality in our cohort was significantly higher from 2014 to 2017. Clinicians should be aware of these risk factors when treating patients with buprenorphine and take steps to mitigate risk in this vulnerable population.

PRELIMINARY FINDINGS FROM THE HISPANIC SECONDARY STROKE PREVENTION INITIATIVE (HISSSI)

Olveen Carrasquillo¹; Jose G. Romano²; ChuanHui Dong²; Sonja Kenya¹; Stuti Dang². ¹University of Miami Miller School of Medicine, Miami, FL; ²University of Miami, Miami, FL. (Control ID #3186396)

BACKGROUND: Latinos face a disproportionate stroke burden and are less likely to have stroke risk factors under adequate control. The objective of this randomized controlled trial is to evaluate the effectiveness of a Community Health Worker (CHW) intervention among Latino patients at risk of recurrent stroke.

METHODS: This is randomized clinical trial of 200 Latino stroke patients in South Florida whom had had a stroke within the last 5 years and were ambulatory (MRS <=3). Participants randomized into the CHW intervention receive health education, health care navigation and social services assistance through home visits and phone calls. Participants also receive daily text messages and are asked to send CHWs their daily home blood pressure readings. The primary outcome is change in systolic blood pressure at 12 months as assessed by trained RA using an automated cuff. Other secondary outcomes include changes LDL, A1C and adherence to anti-thrombotic/antiplatelet medications.

RESULTS: Baseline characteristics were similar with respect to age (61+/19.6 yrs), gender (68% male), proportion having Medicaid (44%), BMI (28.1+/-15.0) and baseline BP (127+/-118mmHg). Intervention participants were more likely to have not completed High school (41% versus 28%). One average over one year, intervention participants received a mean of 7.7 home visits and 31.2 phone calls. Tabulated data on CHW activities showed the majority of CHWs interventions were focused on assistance with social service needs and patient navigation. 68% of patients in the intervention group agreed to receive text messages, and of those 42% responded to at least 50% of their daily text messages. In intention to treat analysis, at one year, of the first 131 enrolled participants, mean SBP was 7.7+/-13.5 lower in the intervention group ($p=0.02$) and DBP was 5.0+/-1.9mmHg lower ($p=.01$). Adjusting for age, gender and baseline BP yielded similar results (SBP 6.4 mmHg and DBP 3.1 lower, $P=.04$ and .03, respectively). At baseline over 50% of participants had an A1c under 6.5% and LDL under 100mg/dl. There were no changes in these two outcomes at one year.

CONCLUSIONS: HISSSI adds to the existing body of literature showing CHWs are an evidence-based approach to improving health outcomes among minority and underserved populations.

PREP RRT: USING THE HOSPITAL AS A SITE TO IDENTIFY, EDUCATE AND REFER HOSPITALIZED MINORITY PATIENTS WITH ADVANCED CKD

Milda R. Saunders²; Akilah King²; Eric Robinson¹; Monica E. Peek³. ¹University of Chicago Medical Center, Chicago, IL; ²University of Chicago, Chicago, IL; ³The University of Chicago, Chicago, IL. (Control ID #3186059)

BACKGROUND: Education for patients with advanced chronic kidney disease (CKD) delays progression to ESRD and improve outcomes in renal replacement therapy (RRT) selection. Yet many minority patients face barriers in receiving pre-ESRD education. The hospital is an important site for patient education and linkage to care for patients with advanced CKD. Over 62% of patients are hospitalized in the year prior to dialysis initiation, and the hospitalization rate rises sharply in the three month prior to dialysis initiation. Thus, we developed and implemented an in-person education intervention for hospitalized African American patients with advanced CKD.

METHODS: Our pilot intervention, the Patient Referral and Education Program prior to Renal Replacement Therapy (PREP-RRT), was developed for hospitalized African American patients and was implemented at a minority-serving academic medical center where the inpatient general medicine population is more than 80% African American. We included hospitalized general medicine patients aged 18-75 who self-identified as African American and who had an estimated glomerular filtration rate (eGFR)<45 mL/min/1.73 m². Participants were recruited through the

Hospitalist Project, an ongoing clinical study that examines a variety of outcomes of hospitalized general internal medicine patients and includes administrative data, inpatient interviews and 30 day follow-up by phone. The PREP-RRT patient educator was an African American nephrology social worker trained in motivational interviewing techniques, CKD self-management and RRT options. During a brief in-hospital session, she assessed patients' current knowledge, focused on their current positive self-care behaviors, assessed barriers and strategies for overcoming these barriers, and then provided knowledge about RRT. Participants were assessed both pre and post-intervention about their knowledge (using Kidney Disease Knowledge Survey (KiKs), attitudes and intent (using an investigator developed instrument) about CKD self-management and RRT options.

RESULTS: We recruited 46 patients over 9 months. Participants were 61% female, mean age 59.5 years. Overall half of patients (56.5%) had CKD Stage 3B, 24% had Stage 4 and 20% had Stage 5 CKD. Despite having advanced CKD, only 33.4% believed they were extremely likely or likely to have kidney failure in the next 5 years. Patient knowledge using KiKs was significantly improved from 63.3% (15.2/24) to 80.2% (19.3/24), $p<0.05$. Participants also appeared to have increased knowledge of RRT modalities, but it reached statistical significance for peritoneal dialysis. There were no significant differences in patient reported intent to participate in CKD self-management or RRT selection.

CONCLUSIONS: PREP RRT was a feasible and effective way to identify, educate and refer hospitalized minority patients with advanced CKD. Increasing patient intent for action around CKD self-care and RRT choice may require a more intensive intervention.

PRESCRIBING ASSOCIATED WITH HIGH-RISK OPIOID EXPOSURES AMONG NON-CANCER CHRONIC USERS OF OPIOID ANALGESICS IN A MEDICAID PLAN: A SOCIAL NETWORK ANALYSIS

Keiki Hinami; Kruti Doshi; Maria Torres; Steven Aks; John J. Shannon; William Trick. Cook County Health, Chicago, IL. (Control ID #3184051)

BACKGROUND: The continued rise in fatalities from opioid analgesics despite a steady decline in the number of individual prescriptions directing 90 morphine milligram equivalents (MME)/day may be explained by patient exposures to redundant prescriptions from multiple prescribers. We evaluated prescribers' specialty and social network characteristics associated with high-risk opioid exposures resulting from single-prescriber high-daily dose prescriptions or multi-prescriber discoordination.

METHODS: We conducted a retrospective cohort study of prescribers with opioid analgesic prescription claims for non-cancer chronic opioid users in an Illinois Medicaid managed care program in 2015-16. We used social network analysis methods to construct a prescriber-beneficiary bimodal sociogram where an opioid analgesic prescription claim represented a tie. Owing to the network's core structure, we assigned k -core levels to each prescriber; k -core is defined as the subset of the network involving prescriber nodes connected to at least k beneficiary nodes. We used negative binomial regression to assess sociometric position and prescriber specialty as risk factors for single-prescriber high-daily- dose prescriptions or multi-prescriber disordinated prescriptions.

RESULTS: For 2280 beneficiaries, 36,798 opioid prescription claims were submitted by 3532 prescribers. Compared to 3% of prescriptions (involving 6% of prescribers and 7% of beneficiaries) that directed 90 MME/day, discoordination accounted for a greater share of high-risk exposures - 13% of prescriptions (involving 23% of prescribers and 24% of beneficiaries). The following specialties were at highest risk of disordinated prescribing compared to internal medicine: dental [Incident Rate Ratio (95% Confidence Interval): 5.9 (4.6, 7.5)], emergency medicine [4.7 (3.8, 5.8)], and surgical subspecialties [4.2 (3.0, 5.8)]. Social network analysis identified 2 small inter-connected prescriber communities of high-volume pain management specialists, and 3 sparsely connected groups of

predominantly low-volume primary care or emergency medicine clinicians. In multivariate models, we found that the sparsely connected sociometric positions were a risk factor for high-risk exposures.

CONCLUSIONS: Low-volume prescribers in the social network's periphery were at greater risk of intended or disordinated prescribing than interconnected high-volume prescribers. Interventions addressing disordination among low-volume opioid prescribers in non-integrated practices should be a priority. Demands for enhanced functionality and integration of Prescription Drug Monitoring Programs or referrals to specialized multidisciplinary pain management centers are potential policy implications.

PRESCRIPTION OPIOID USE INCREASES ODDS OF OBSTRUCTIVE SLEEP APNEA

Kevin Chen^{1, 2}; David A. Fiellin¹; Henry Yaggi¹; Lori A. Bastian². ¹Yale University School of Medicine, New Haven, CT; ²VA Connecticut Healthcare System, West Haven, CT. (Control ID #3176031)

BACKGROUND: Prescription opioids can complicate obstructive sleep apnea (OSA) due to their ability to disrupt sleep architecture, induce central apneas, worsen upper airway obstruction, and deepen arousal thresholds. While continuous positive airway pressure (CPAP) is a standard treatment for OSA, it may not be optimal for opioid-related central apneas. Understanding patterns of prescription opioid use, OSA, and CPAP use may impact OSA screening and treatment in patients prescribed opioids. We sought to determine the association between prescription opioids, OSA, and CPAP use.

METHODS: Using the Women Veterans Cohort, we identified female and male veterans of recent wars who were prescribed opioids and the prevalence of OSA and CPAP, assessed by International Classification of Disease-9 and Current Procedural Terminology codes. Demographics and comorbidities were compared for patients across opioid prescription categories (none, acute, chronic—defined as being prescribed 90 annual opioid days). Bivariate and multiple logistic regression were used to test for associations between opioid prescription category, OSA, and CPAP. Known risk factors for OSA, including age, sex, obesity, smoking status, race, psychiatric disease, pain intensity (numeric rating scale: none=0, mild=1-3, moderate=4-6, severe=7-10), pulmonary disease, heart failure, stroke, traumatic brain injury, and substance use were controlled for.

RESULTS: A total of 1,149,874 veterans were assessed for inclusion. The mean age was 38.0 ± 9.6 (SD) years. 136,754 had any opioid prescription, and 29,034 (2.5%) had chronic opioid prescriptions. 115,379 (10.0%) veterans had a diagnosis of OSA, of which 41,033 (35.6%) received CPAP. Compared to veterans without opioid prescriptions, those with opioid prescriptions were more likely to be older, female (13.1% v 12.2%), obese, current or former smokers, have moderate or severe pain intensity, and have psychiatric and medical comorbidities ($p<0.01$ for all comparisons). Both acute (unadjusted OR 3.49 [95% CI 3.43, 3.54], aOR 1.82 [1.79, 1.86]) and chronic (OR 4.75 [4.62, 4.87], aOR 1.91 [1.85, 1.97]) opioid prescriptions were associated with increased odds of having OSA compared to people who did not have opioid prescriptions. People who had opioid prescriptions also had higher odds of CPAP compared to those without (acute: OR 1.15 [1.11, 1.18], aOR 1.08 [1.05, 1.12]; chronic: OR 1.30 [1.24, 1.36], aOR 1.16 [1.10, 1.22]).

CONCLUSIONS: As patients prescribed opioids are more likely to have OSA, clinicians should screen for sleep-disordered breathing in individuals being prescribed opioids chronically. And, since opioid use is associated with CPAP, the efficacy of CPAP in opioid-related sleep apneas should be further studied.

PRESENCE: PHYSICIAN AND NON-PHYSICIAN INSIGHTS ABOUT THE ART OF HUMAN CONNECTION IN CLINICAL ENCOUNTERS

Cati Brown-Johnson²; Rachel Schwartz¹; Amrapali Maitra²; Marie C. Haverfield³; Aaron A. Tierney⁴; Jonathan G. Shaw²; Dani L. Zions²; Nadia Safaeinili⁵; Sonoo Thadaney⁵; Abraham Verghese⁵; Donna M.

Zulman⁶. ¹Stanford University, Menlo Park, CA; ²Stanford University School of Medicine, Stanford, CA; ³Veterans Affairs, Menlo Park, CA; ⁴Stanford University School of Medicine, Mountain View, CA; ⁵Stanford University, Stanford, CA; ⁶Stanford University and VA Palo Alto, Stanford, CA. (Control ID #3185651)

BACKGROUND: Physician disenchantment and burnout are driving demand for strategies that facilitate "clinician presence" and foster meaningful human connection during medical encounters. We sought to investigate the concept of presence through interviews with primary care physicians and diverse non-medical professionals from fields in which human connection is central.

METHODS: We conducted 40 semi-structured interviews with physicians (n=10) and non-medical professionals (n=30) to explore how they create connection, engage in interpersonal interaction, and build trust with individuals across different circumstances and contexts. Physicians originated from primary care clinics in three settings that include a community safety-net system, an academic medical system, and a Veterans Affairs facility. Non-medical professionals represented diverse fields, including protective services (e.g., police officer, firefighter), business (e.g., restauranteur, salesperson), management (CEO, school principal), education, art/design/entertainment (e.g., professional musician, documentary filmmaker), and social services (social worker, chaplain). Interviews were recorded and transcribed; we used a constant comparative method to code transcripts as a research team. Interview excerpts relevant to presence were independently analyzed by two qualitative researchers to generate core elements of presence. These elements were iteratively refined into a working definition of presence through team discussions and research meetings.

RESULTS: Data synthesis generated a definition for presence as, "a purposeful practice of awareness, focus, and attention with the intent to understand and connect with individuals/patients." For both medical and non-medical professionals, creating presence requires managing and considering time and environmental factors; for medical professionals in particular, this includes managing and integrating technology. Listening was described as central to creating the state of being present. Within a clinical setting, presence might manifest as a physician listening without interrupting, focusing intentionally on the patient, taking brief re-centering breaks throughout a clinic day; and informing patients when attention must be redirected to administrative or technology demands.

CONCLUSIONS: Clinician presence involves learning to step back, pause, and prepare to receive a patient's story. Building on strategies from physicians and non-medical professionals, clinician presence is best enacted through purposeful intention to connect, conscious navigation of time, and proactive management of technology and the environment in order to focus attention on the patient. Everyday practice or ritual supporting these strategies is paramount and could support physician self-care as well as physician-patient connection.

PREVALENCE AND DETECTION OF COGNITIVE IMPAIRMENT IN PRIMARY CARE.

Laura M. Curtis¹; Rebecca Mullen¹; Rachel O'Conor¹; Julia Yoshino Benavente¹; Mary J. Kwasny¹; Marina Arvanitis¹; Derin Cobia³; Alex Federman²; Michael S. Wolf⁴. ¹Northwestern University, Chicago, IL; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³Brigham Young University, Provo, UT. (Control ID #3185447)

BACKGROUND: Cognitive impairment can affect one's ability to effectively understand and independently self-manage health and healthcare. Despite incomplete guidelines regarding screening, primary care is an optimal place for detecting impairments, as it may inform clinical decision making, referrals, and opportunities to involve families and other caregivers in a patient's care. We sought to determine the prevalence of cognitive impairment among an ongoing cohort of community dwelling older adults and to determine whether any type of impairment was documented in patients' medical charts.

METHODS: 610 adults between the ages of 55 and 74 were recruited from a

general internal medicine ambulatory care clinic in Chicago. Structured interviews were conducted at baseline between 2008 and 2010 and participants, to date, have been followed every 2.5-5 years. Impairment was determined using an extensive neuropsychological battery covering five domains and categorized as mild, moderate, or severe. ICD codes for dementia, mild cognitive impairment (MCI), and other cognitive-related deficits were extracted from participants' medical charts from enrollment date through December 2018. Detection was defined in those with cognitive impairment if an ICD code was documented prior to or within one year after impairment was assessed. Impairment and detection variables were compared by sociodemographic characteristics and health status.

RESULTS: Participants were 70% female, 28% African American, 64% White, had a mean (SD) age of 63.4 (5.5) at baseline and mean follow-up time of 7.1 (2.0) years. We detected impairment in 33% over the course of the existing study period post-baseline (n=204); 52.5% of these had mild, 26.5% moderate, and 21.0% severe cognitive impairment. Impairment was associated with older age, lower education and income, and greater co-morbidity. In those with impairment, 30 (15%) were detected within a year; an additional 35 (17%) were detected an average of 5.2 (SD=2.5; range 1.1-10.1) years later. Detection within a year was associated with older age (mean 68.5 (6.8) vs 65.0 (6.1), p=0.005) and greater co-morbidity (mean 3.5 chronic conditions (1.8) detected vs. 2.8 (1.7) undetected, p=0.02) at the time of impairment. Detection was not associated with education or income.

CONCLUSIONS: Findings from this single-site investigation reveal a prevalence of cognitive impairment much higher than prior studies have reported. Rates of detection were exceptionally low, with more cases detected long after the patient may have exhibited worsening abilities. Further research is needed to better understand whether similarly high rates of impairment may be found in diverse primary care settings, and ways to improve case finding and referrals.

PREVALENCE AND IMPACT OF PRIOR TRAUMA EXPOSURE AMONG PATIENTS PRESENTING TO THE EMERGENCY DEPARTMENT WITH SUSPECTED ACUTE CORONARY SYNDROME

Justin Young¹; Adam Schweber¹; Jennifer A. Sumner²; Laura Meli²; Ian M. Kronish². ¹Columbia University Vagelos College of Physicians and Surgeons, New York, NY; ²Columbia University Medical Center, New York, NY. (Control ID #3183625)

BACKGROUND: Trauma exposure is associated with higher rates of psychiatric morbidity, negative health outcomes, and greater vulnerability to retraumatization during acute medical care, particularly among patients who develop PTSD symptoms related to the trauma. Few studies have assessed the prevalence and impact of prior trauma exposure and associated PTSD symptoms in patients presenting in the emergency department (ED) setting for suspected acute coronary syndrome (ACS). We quantified (1) the prevalence of prior trauma exposure and PTSD symptoms among patients presenting to the ED for suspected ACS and (2) the risk of developing elevated PTSD symptoms after suspected ACS given the presence of elevated PTSD symptoms due to prior trauma.

METHODS: From 2014-2018, we enrolled a consecutive sample of patients presenting to the ED of an urban, academic medical center for suspected ACS. Prior trauma exposure was evaluated using the Life Events Checklist (LEC-5), assessing lifetime exposure to 17 types of traumas. Patients also identified the most distressing prior event. Past-month PTSD symptoms associated with the most distressing event were assessed using the 17-item PTSD Checklist (PCL-S); PTSD symptoms due to the suspected ACS were again measured with the PCL-S at 1-month. A PCL-S score >=34 indicated elevated PTSD symptoms. Modified Poisson regression was used to estimate the relative risk of developing elevated PTSD symptoms associated with the suspected ACS event contingent on whether the patient had prior elevated PTSD symptoms. A variety of demographic and clinical variables were included as potential confounders.

RESULTS: Of 932 patients presenting to the ED for suspected ACS (mean

age 60.8 years, 46.5% women, 56.7% Hispanic), 73% (n=712) had experienced at least one type of prior traumatic event. Among trauma-exposed participants, the median number of trauma types was 3.0 (range=1-16), with the most common types including transportation accident (32.2%), natural disaster (29.7%), and life-threatening illness/injury (20.4%). 21% of participants (n=196) had elevated PTSD symptoms due to their most distressing prior trauma. 42.2% of these patients with probable PTSD from prior trauma developed elevated PTSD symptoms due to the suspected ACS at 1-month follow-up. In contrast, only 9.6% of patients without elevated symptoms due to prior trauma developed elevated PTSD symptoms after suspected ACS. When adjusting for demographic and clinical variables, the adjusted relative risk was 4.1 (95% CI: 3.0-5.6; p<.001).

CONCLUSIONS: Our findings indicate that among patients presenting with suspected ACS in an urban ED, there is a high prevalence of trauma exposure and associated PTSD symptoms. Patients with elevated PTSD symptoms due to prior trauma are at markedly increased risk of developing subsequent PTSD symptoms related to a suspected ACS event, suggesting that prior trauma-related psychopathology is associated with greater vulnerability to developing PTSD symptoms after a suspected ACS event.

PREVALENCE AND PREDICTORS OF IMPOSTER PHENOMENON AMONG HARVARD MEDICAL STUDENTS

Alison M. Holliday¹; David E. Leaf^{3, 1}; Galina Gheihman¹; Cynthia M. Cooper^{2, 1}; Amy M. Sullivan¹; Rebecca Karp Leaf^{2, 1}. ¹Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Brigham and Women's Hospital, Boston, MA. (Control ID #3179336)

BACKGROUND: The Imposter Phenomenon (IP) is a psychological construct characterized by feelings of inadequacy, drive for perfectionism, and fear of being discovered as a "fraud" by colleagues and supervisors. IP is known to limit performance and professional growth, and is associated with high rates of anxiety and burnout. Although IP is known to occur commonly among high-achieving individuals in various professional fields, limited data are available on IP among medical students.

METHODS: We conducted a cross-sectional web-based survey of all Harvard Medical and Dental School students to identify the prevalence and predictors of IP. We used the Clance Imposter Phenomenon Scale (CIPS), which is a validated instrument for assessing IP. CIPS consists of 20 questions based on a 5-point Likert scale, with a score of 62 or higher corresponding with experiencing IP and a score of 80 or higher corresponding with experiencing intense IP. The survey was distributed between June and August 2018 via an email distribution list. We collected demographic data including age, gender, race, ethnicity, medical school track (MD/PhD, Health Sciences and Technology/physician-scientist, etc.), intended medical specialty, college major, whether the student took time off prior to medical school, and whether the student had a first-degree family member in medicine. We used logistic regression to identify predictors of IP.

RESULTS: Of the 753 students surveyed, 519 (68.92%) responded, with 485 (93.45%) completing all 20 CIPS questions. Among students who completed the CIPS questions, 285 (58.76%) had a score of 62 or higher, corresponding with experiencing IP, and 72 (14.85%) had a score of 80 or higher, corresponding with experiencing intense IP. Predictors of intense IP included female gender (odds ratio [OR] 1.95, 95% confidence interval [CI] 1.15 to 3.31, p=0.01), time off prior to medical school (OR 1.77, 95% CI 1.07 to 2.93, p=0.03), and age (years, OR 1.11, 95% CI 1.02 to 1.22, p=0.02). There was no association between intense IP and Caucasian race (p=0.40), having a first-degree family member who is a physician (p=0.76), or intention to pursue a surgical specialty (p=0.99).

CONCLUSIONS: IP is widespread among students at Harvard Medical and Dental School, particularly among women. Future research is needed to understand the relationship between IP and academic performance, as well as the progression of IP over time during residency, fellowship, and attending years.

PREVALENCE AND PREDICTORS OF PLEURAL EFFUSION

IN CONGESTIVE HEART FAILURE

Oreoluwa Oladiran; Rashmi Dhitlal. Reading Hospital, Wyomissing, PA. (Control ID #3180664)

BACKGROUND: Pleural effusion is common in congestive heart failure (CHF) and usually portends a poor prognosis, however its prevalence and distribution is not well documented in literature. We sought to query a large national database to determine the prevalence, demographic and clinical factors associated with cardiogenic pleural effusions.

METHODS: We used National (Nationwide) Inpatient Sample database, the largest publicly available all-payer inpatient database in the US that contains ~20% sample of all US hospitalizations (>7 million hospital stays each year), to identify adult inpatients with the diagnosis of CHF and pleural effusion using ICD-9 codes. We excluded cases citing other possible causes of pleural effusion including liver cirrhosis, infectious and malignant effusions, and then compared various demographic and clinical factors among CHF in-patients with or without pleural effusion.

RESULTS: In the years 2012 and 2013, after excluding other common etiologies of pleural effusion, a total of 1,172,067 patients were admitted with CHF in the United States, out of which 40,319 (3.4%) were coded for as pleural effusion. Heart failure patients with a pleural effusion were older than those without (74.9 versus 72.1 years, p<0.001), more likely Caucasian (76% versus 70%, p<0.001). They were also found to have had a significantly increased length of stay (9.0 vs 5.4 days, p<0.001) and significantly higher inpatient mortality (6.2% versus 3.2%, p<0.001).

CONCLUSIONS: Among patients with heart failure, pleural effusion is uncommon, but is associated with higher lengths of stay and higher inpatient morbidity. Whether this is the reflection of poorer cardiac function or is an independent predictor of adverse outcomes is a matter for further study.

| | CHF with pleural effusion N= 201,595 | CHF without pleural effusion N= 5658739 | P-value |
|----------------------------------|---|--|---------|

PREVALENCE OF ASPIRIN USE FOR PRIMARY PREVENTION OF CARDIOVASCULAR DISEASE

Colin W. O'Brien; Stephen P. Juraschek; Christina C. Wee. Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #3175838)

BACKGROUND: Multiple practice guidelines have recommended use of aspirin (ASA) for primary prevention of cardiovascular disease (CVD) in adults at increased risk. However, three randomized control trials published in 2018 - ASCEND, ARRIVE and ASPREE - demonstrated minimal benefits and consistent bleeding risks, particularly for older adults. Our goal was to quantify aspirin use and characterize factors associated with use among US adults who take aspirin for primary prevention.

METHODS: We used the 2017 National Health Interview Survey (NHIS), a nationally representative in-person household survey, to examine rates of self-reported aspirin use to prevent heart disease among US adults aged 40 and older without CVD. We used multivariable logistic regression to

characterize demographic and clinical factors associated with aspirin use. Analyses were weighted and adjusted using SAS 9.4 to account for the complex NHIS sampling design.

RESULTS: The mean age of our study sample was 57.5 years. Of this sample, 54% were women and 33% were non-white. There were 23.4% of adults 40 years without CVD taking a daily aspirin for the prevention of heart disease, representing approximately 29 million people. Among this population, 22.8% did so without a physician's recommendation. Aspirin use was higher with greater age: 7% of those aged 40-49 without CVD reported aspirin use, compared to 46.2% aged 80 or older. After adjustment, older age and male sex were significantly associated with aspirin use (see table), as were Asian race (compared to white), diabetes, hypertension, hyperlipidemia, obesity, smoking, and having seen a doctor in the previous year. Peptic ulcer disease was not significantly associated with aspirin use, OR 0.90 (95% CI 0.74 - 1.09).

CONCLUSIONS: Over 29 million US adults aged 40 and older without CVD use aspirin to prevent heart disease, including many octogenarians and adults with a history of peptic ulcer disease. This study highlights an important role for physicians to discuss the latest aspirin trials' findings with US adults to minimize risks and optimize benefits from aspirin use.

| Characteristic | Prevalence of ASA Use (%) | Odds of ASA Use (AOR*, 95% CI) |
|----------------|---------------------------|--------------------------------|
| Sex | | |
| Men | 25.5% | 1.32 (1.18 - 1.48) |
| Women | 21.8% | 1.00 |
| Age | | |
| 40-49 | 7.0% | 1.00 |
| 50-59 | 18.4% | 2.52 (2.11 - 3.01) |
| 60-69 | 34.7% | 5.55 (4.59 - 6.71) |
| 70-79 | 44.6% | 7.71 (6.35 - 9.35) |
| 80+ | 46.2% | 9.62 (7.56 - 12.25) |

*Also adjusted for race, BMI, HTN, HLD, DM, ulcer disease, smoking, and seeing a physician in the last year.

Aspirin Use Among Adults 40+ Without CVD

PREVALENCE OF INTERNAL MEDICINE RESIDENTS WITH AN ESTABLISHED PRIMARY CARE PROVIDER

Mark Connor; Robert L. Fogerty. Yale School of Medicine, New Haven, CT. (Control ID #3185782)

BACKGROUND: The benefits of having an established primary care provider (PCP), especially in regards to decreased all-cause mortality and improved mental illness outcomes, is well established. CDC data indicates that the national averages for US men and women without a primary care physician are 28% and 17%, respectively, and 19% and 10% in Connecticut. Recent healthcare trends have highlighted that millennials, those born between 1981 and 1996, are opting for more expedited and convenient access to medical care, thereby moving away from establishing and maintaining a primary care provider. The prevalence rate of resident physician trainees, the majority of whom are millennials, that have established care with a primary care doctor as well as their opinion towards having a PCP are currently unknown.

METHODS: An electronic twenty-question survey of privately insured, internal medicine residents with a response rate of 67.3% at a large academic center in Connecticut was utilized to determine various aspects of resident wellness including whether or not residents established care with a local primary care physician and their opinion regarding the utility of establishing care with a local primary care physician.

RESULTS: While 90% of the survey responders believe it is worthwhile to establish care with a local primary care physician, the survey found that 57% of resident physicians (57.3% women, 57.1% men) had not established care with a local primary care provider. Per the CDC, the prevalence rates of Connecticut adults aged 25-34 years and 35-44 years not having a PCP are 30.6% (CI 26.7-34.4%) and 17.9% (CI 15.0-20.9%), respectively. These data suggest that internal medicine residents are establishing with primary care providers at a lower rate than age and geographically matched peers.

CONCLUSIONS: The survey suggests that although internal medicine residents believe it is valuable to establish care with a primary care provider, residents may be establishing with a primary care provider at a lower rate than age and geographically matched peers. These findings are of interest to residency programs directors due to concerns for wellbeing, including physician burnout of internal medicine residents. Additionally, these data suggest that there may be barriers to establishing care that warrant further investigation.

PREVALENCE OF MULTIPLE CHRONIC CONDITIONS BY US STATE, 2017

Daniel Newman; Erica Levine; Sandeep Kishore. Icahn School of Medicine at Mount Sinai, New York, NY. (Control ID #3162709)

BACKGROUND: Understanding the prevalence of multiple (two or more) chronic conditions (MCC) is increasingly being recognized as a public health imperative. MCCs are associated with increased cost, increased burden of illness, and decreased quality of life. The objective of this research is to describe the prevalence and distribution of adults with MCC across the United States using 2017 data from the Behavioral Risk Factors Surveillance System (BRFSS).

METHODS: Prevalence of MCC (defined as having two or more of 12 diagnosed chronic conditions) was calculated for each U.S. state and territory overall as well as by sex and age.

RESULTS: Statewide prevalence of MCC ranged from 37.9% in the District of Columbia to 64.4% in West Virginia. Females had a higher prevalence than males in 47 of 53 (89%) states and territories, and MCC prevalence increased with age in every state and territory.

CONCLUSIONS: The relative geographic and demographic distribution of MCC prevalence is largely consistent with prior research using data from the National Health Interview Survey (NHIS); however, overall prevalence estimates are noticeably higher due partly to the inclusion of high cholesterol, obesity, and depression as chronic conditions. This analysis is, to our knowledge, the first to analyze MCC prevalence across the United States using BRFSS data. Further, it extends and expands on prior research into the nationwide prevalence of MCC by incorporating more chronic conditions and using the most recent data available. These findings help to build an accurate and granular picture of the prevalence of multiple chronic conditions across the United States and will aid public health officials in creating programs targeted to their region.

PREVALENCE OF POLYPHARMACY IN OLDER ADULTS - A CROSS-SECTIONAL ANALYSIS

Michael I. Ellenbogen¹; Peiqi Wang¹; Heidi Overton¹; Christine Fahim²; Angela Park¹; William Bruhn¹; Jennifer L. Carnahan³; Amy Linsky⁴; Seki Balogun⁵; Martin Makary¹. ¹Johns Hopkins School of Medicine, Baltimore, MD; ²Health Policy and Management, Baltimore, MD; ³Indiana University Center for Aging Research/Regenstrief Institute, Indianapolis, IN; ⁴VA Boston Healthcare, Boston, MA; ⁵University of Virginia, Charlottesville, VA. (Control ID #3180213)

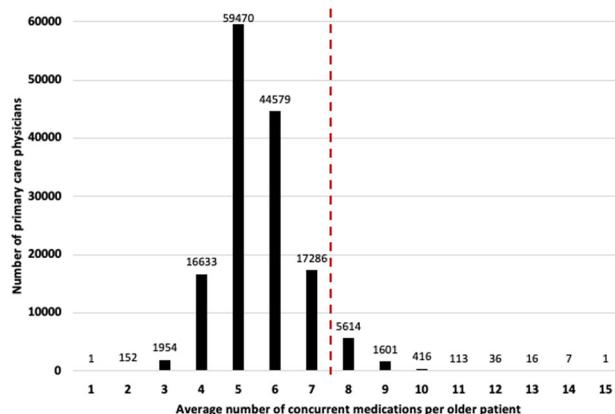

BACKGROUND: Polypharmacy in older patients increases the risk of medication-related adverse events and can be a marker of unnecessary care. We sought to describe the prevalence of polypharmacy among patients 65 years of age or older and identify factors associated with patient-level and physician-level polypharmacy prescribing.

METHODS: We performed a cross-sectional analysis of 100% Medicare claims data from January 1 to December 31, 2016. All patients with continuous Medicare fee-for-service insurance (Parts A, B, and D) throughout 2016 who were 65 years of age or older and who were prescribed at least one medication for at least 30 days during this time were included. Each patient was attributed to the primary care physician (PCP) who prescribed them the most medications. PCPs treating fewer than ten patients were excluded. We defined polypharmacy as the highest number of concurrent medications at any point during the year. We characterized the distribution of PCPs prescribing by these metrics. We used hierarchical linear regression to study patient- and physician-level characteristics associated with high prescribing rates.

RESULTS: We identified 25,747,560 patients attributed to 147,879 PCPs. The patient-level mean concurrent medication rate was 5.6 (standard deviation 3.3). The physician-level mean number of concurrent medications was 5.6 (range 1.3-14.8; sd 1.08). The cutoff for high outlier physician was 7.7 ($=5.6 + 2 \times 1.08$) concurrent medications per patient (Figure 1), which identified 4.1% of all physicians as outliers (6,108 physicians). A number of patient-level factors were associated with an adjusted increase in concurrent medications greater than 1.00 including: an Elixhauser score of 5 or more (2.49; 95% confidence interval 2.49-2.50), history of solid organ transplant (1.32; 1.27-1.37), diabetes (1.39; 1.39-1.40), and HIV/AIDS (1.89; 1.84-1.94).

CONCLUSIONS: Patterns of high prescribing to older patients are common and measurable at the physician-level. Addressing high outlier prescribers may represent an opportunity to reduce avoidable harm and excessive costs.

Figure 1. National distribution of physician-level mean concurrent medications

Note: Dashed red line indicated 2 standard deviations above mean number of concurrent medications ($7.7 = 5.6 + 2 \times 1.08$)

PRIMARY CARE HOME VISITS AND HEALTHCARE UTILIZATION: A COHORT STUDY

Xin Zhang; Jennifer Manggaard; Ondler Hinson Heather; Paul Takahashi. Mayo Clinic, Rochester, MN. (Control ID #3181442)

BACKGROUND: While the outpatient office is the traditional care delivery model for primary care, primary care home visits are important to provide care for frail elderly patients. These patients have difficulty with functional limitations, socioeconomic reasons, and lack of transportation in coming into clinic. While some primary care providers and geriatric fellows perform home visits to provide care for those patients, but we do not know the healthcare utilization for this important group of patients. In this study, we aim to describe the patients who are served and describe emergency department (ED) visits and hospitalizations within 90 days of index home visit date.

METHODS: We evaluated all patients 65 years of age who had home visits and who were not enrolled in post-hospitalization transition, palliative or hospice programs from 2010-2017. Descriptive statistics were used to examine patient demographics and comorbidity health burden. ED visits and

hospitalizations within 90 days post index home visit were collected.

RESULTS: A total of 609 patients, 181 males and 427 females, were included. Average age at time of home visit was 85 years (65-105 years). Majority of the subjects were Caucasians (561, 92%) and a minority were married (196, 32%). 43% of patients (260) were community dwelling, while the majority lived in assisted living. Most common medical conditions include hypertension (72%), dementia (51%), depression (34%), cancer (28%), osteoporosis (28%), coronary artery disease (25%), cardiac arrhythmia (25%), diabetes (21%), and congestive heart failure (18%). 189 (31%) patients had ED visits within 90 days; 68 % (129) had 1 visit and 32% (6) had 1 visit. Most common reasons for ED visit were fall (20%), dyspnea (8%), altered mental status (8%), and musculoskeletal pain (8%). 137 patients (22%) had hospitalizations within 90 days; 90 (66%) had 1 and 47 (34%) had 1 hospitalizations. The main diagnosis for hospitalization includes infection (15%), fall and/or fracture (12%), behavioral disturbance (8%), and heart failure (5%).

CONCLUSIONS: In our patient population, 31% had ED visits and 22% had hospitalizations in 90 days after home visits. The 90 day hospitalization rate was 29.9% in a prior study on identified high risk patients who were involved in a post-hospitalization care transitions program at the Mayo Clinic¹. We found a similar 90 day hospitalization rate compared to that study, which suggests that our patients are similarly frail, medically complex, and prone to ED visits and hospitalizations. Further study is needed to improve care for this high risk population. 1. Takahashi PY, Naessens JM, Peterson SM, et al. Short-term and long-term effectiveness of a post-hospital care transitions program in an older, medically complex population. *Healthc (Amst)*. 2016;4(1):30-35.

PRIMARY CARE PHYSICIANS' KNOWLEDGE OF THE CARDIOVASCULAR EFFECTS OF DIABETES MEDICATIONS

Jay H. Shubrook²; Jonathan Pak¹; George E. Dailey³. ¹Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT; ²Touro University, Fairfield, CA; ³Scripps Health, La Jolla, CA. (Control ID #3176456)

BACKGROUND: Cardiovascular (CV) disease is a leading cause of death in patients with type 2 diabetes (T2D). Several CV outcomes trials (CVOTs) have shown that specific antidiabetes agents improve CV outcomes in patients with T2D and high CV risk or CV disease. This survey examined knowledge and beliefs about CVOTs among US internal medicine (IM) and family physicians (FP).

METHODS: A 23-item survey was administered by WebMD, LLC. from Sept 18-20, 2018. The survey was sent to 47,534 Medscape members who were randomly selected across US regions and specialties (quota, 250 per specialty). A z-test was used for statistical comparisons. The Touro University California IRB deemed that the study protocol met exemption criteria (TUC IRB #M-3118).

RESULTS: Overall, 702 physicians responded, 199 did not meet eligibility criteria and 503 completed the survey. Familiarity with CVOTs was low, with 8-42% of respondents indicating that they were moderately or extremely familiar with each of 14 CVOTs listed. Respondents reported that they were more familiar with TECOS, LEADER, EMPA-REG OUTCOME and CANVAS than other CVOTs ($P < .05$). Also, 38%, 33%, 28% and 11% correctly responded that EMPA-REG OUTCOME, LEADER, CANVAS and SUSTAIN-6, respectively, showed superiority vs placebo for the primary composite major adverse CV event [MACE] endpoint; 26% did not know. Similarly, 31% of respondents did not know which CVOTs showed superiority for CV mortality; 36% and 26% correctly chose EMPA-REG OUTCOME and LEADER. Nearly half did not know which CVOT showed superiority for heart failure hospitalization. More than half of respondents incorrectly thought that acute pancreatitis occurred significantly more frequently with DPP-4 inhibitors or GLP-1 RAs vs placebo. Only 8% knew that retinopathy occurred more frequently with semaglutide than placebo in SUSTAIN-6. CANVAS was not well recognized for its risk of lower limb amputations (36% selected CANVAS alone). However, 69% recognized the increased rate of genital infections with SGLT2 inhibitors in EMPA-REG OUTCOME, CANVAS, or both trials.

CONCLUSIONS: Findings suggest knowledge gaps among IMs and FPs regarding CVOT results, which has implication for the treatment of patients with T2D and CV disease.

PRIMARY CARE PROVIDER ATTITUDES AND PERSPECTIVES ON HEPATITIS C VIRUS (HCV) MANAGEMENT IN PRIMARY CARE

Yvette Ryan; Aaron Null; Sopheap Na. Rocky Mountain Regional VA Medical Center, Aurora, CO. (Control ID #3184621)

BACKGROUND: The limited availability of specialists to treat the 2.4 million Americans living with Hepatitis C virus (HCV) has led to the idea of shifting HCV management to primary care providers (PCPs). Although a recent study demonstrated HCV treatment by PCPs is as safe and effective as treatment by specialists, it is not known how PCPs feel about adding HCV treatment to the burden of chronic diseases they already manage. In this qualitative study, we explored PCP attitudes and opinions towards managing HCV and how they view the role of clinical pharmacists in taking on this role.

METHODS: We performed semi-structured interviews of 10 PCPs at a VA Medical Center, representing PCPs at both the main campus and community clinics. We conducted interviews both in-person and via telephone, using purposive sampling. The interview guide addressed chronic disease management (CDM) burden in primary care, facilitators and barriers to PCPs treating HCV, and how PCPs view clinical pharmacists in CDM within the VA system. We transcribed all interviews at time of the interview and maintained field notes. We utilized open coding with all interviews coded independently by two members of the team and reconciled coding differences jointly.

RESULTS: Of participating PCPs, 20% thought that PCPs could take on HCV treatment and management in their current work environment. We identified themes of limited PCP access and provider education as the most prominent barriers to PCPs managing HCV treatment. Providers identified PharmDs as valuable partners in CDM, and most thought they can facilitate treatment of HCV in primary care. PCPs found clinical pharmacists helpful in improving patient access, patient safety, and were strong allies in team based care. Despite having HCV trained clinical pharmacists available to co-manage HCV screening and treatment in primary care, none of the participating PCPs were fully aware of this existing support structure. Some PCPs expressed concern that PharmD co-management of HCV treatment would limit their own knowledge and skill in treating HCV independently.

CONCLUSIONS: Although evidence suggests HCV treatment in primary care has similar outcomes to treatment by specialists, PCPs appear reluctant in taking on this responsibility. While HCV treatment in primary care is a promising strategy, health systems need to be cognizant of PCP access and the CDM burden PCPs already face. PCPs do value clinical pharmacist co-management of chronic diseases and further integration of such workflows may improve access, allowing more patients with HCV to be treated. Despite HCV trained PharmDs being in place at the VA, there is limited PCP knowledge about them and more effort needs to be performed to ensure dissemination and utilization of these clinical support structures.

PRIMARY CARE PROVIDER GENDER SENSITIVITY TOWARD WOMEN PATIENTS AFFECTS PATIENT CONTINUING USE OF CARE

Claire Than³; Donna L. Washington¹; Danielle Rose²; Ismelda Canelo^{4, 3}; Elizabeth M. Yano³. ¹VA Greater Los Angeles Healthcare, UCLA, Los Angeles, CA; ²VA GLA Healthcare System, Sepulveda, CA; ³VA Greater Los Angeles Healthcare System, Sepulveda, CA; ⁴VA Greater Los Angeles Healthcare System, North Hills, CA. (Control ID #3183133)

BACKGROUND: Provider gender sensitivity means that providers are empathetic towards women patients and understand their health care needs. Gender sensitivity has assumed increasing importance in health care as it can affect women patients' experiences with care. Women veterans (WVs) are an extreme numerical minority of patients (<10%) seen at the Veterans Health Administration (VA), and about 20-25% of them discontinue using VA within three years of first VA care use. A high rate of WV leaving VA raises concerns on their experiences with VA care. Literature suggests that WV are more likely to report poor satisfaction with VA care and to not use VA care when VA providers are not sensitive to their needs. We evaluated whether provider gender sensitivity is associated with patient discontinuing use of VA care.

METHODS: We used cross-sectional surveys to measure primary care provider (PCP) gender sensitivity based on agreement with 10 items, e.g. "VA should not be expected to provide special health services for women". We surveyed 281 PCPs at 12 VA Medical Centers between September 2014 and June 2015. A total of 94 PCPs completed the surveys (33% response rate). We identified WV patients cared for by these PCPs in VA outpatient clinics between January 2013 and December 2014. We defined patient discontinuity from PC as having no in-person or telephone visits to any VA PC clinics within three years following their last visits to PCPs in the surveys, i.e. from their last visits between 2013 and 2014 to December 2017. Our analyses included 7,155 WV who were seen by these PCPs between 2013 and 2014 and were alive through 2017. We used multivariate logistic regression to evaluate the relationship between PCP gender sensitivity and WV discontinuity from VA PC.

RESULTS: Overall, 32% of WV in our sample had no visit to PC over three years. Multivariate regression showed that higher PCP gender sensitivity was significantly associated with lower odds of patient discontinuity from VA PC (Adjusted OR=0.80, 95% CI: 0.70, 0.91), but this association differed by age group. Among WV in the 18-39 age group, higher PCP gender sensitivity predicted lower odds of WV discontinuing PC use (AOR=0.64, 95% CI: 0.44, 0.95). Among WV in the 40-49, 50-59 and 65+ age groups, gender sensitivity was not associated with care discontinuity. Among WV in the 60-64 age group, higher gender sensitivity predicted lower odds of patient discontinuing PC use (AOR=0.59, 95% CI: 0.37, 0.95).

CONCLUSIONS: PCP gender sensitivity was associated with patient's continuing use of VA PC, especially among younger WV. Future efforts to improve and/or maintain high PCP gender sensitivity can help ensure continuity of care for women patients. An understanding of reasons for their care discontinuity, e.g. not needing care or receiving care elsewhere, may help inform efforts to increase or maintain WV use of VA care.

PRIMARY CARE PROVIDER PERSPECTIVES ON CALCULATED VERSUS ADJUDICATED RISK STRATIFICATION IN PRIMARY CARE: A QUALITATIVE STUDY

Brian Ricci¹; David Dorr². ¹Oregon Health and Science University, Portland, OR; ²OHSU, Portland, OR. (Control ID #3185751)

BACKGROUND: Risk stratification (RS) is a process by which a population of empaneled patients are assessed for risk of poor health outcomes by an algorithm with or without a human review process (known as adjudication). RS computer algorithms seek to predict healthcare utilization, costs, morbidity and mortality, but are often limited to only specific factors calculable in the original data, such as from an electronic health record (2). However, confidence in RS processes are increased when computer-derived scores are adjudicated by providers with patient-specific knowledge (3). Using a natural health reform experiment, our objective was to identify factors that are considered by providers during the adjudication process.

METHODS: In the Comprehensive Primary Care+ (CPC+) initiative from the Center for Medicare and Medicaid Innovation, RS with

adjudication was required to identify high needs patients, especially those at risk of exacerbations leading to hospitalization or ED utilization. For our study we used the Epic Risk Score tool which has been validated to specifically predict hospitalizations and ED utilization (AUC 0.63-0.78 at three different sites). Participating primary care providers in one CPC+ practice received instruction on the RS tool prior to participation in this study. We used a think aloud protocol and structured interviews with providers as they adjudicated their own patient panels. We used a modified immersion/crystallization approach to analyze responses into factors and themes.

RESULTS: Ten PCPs participated, adjudicating a total of 2500 patients. Overall providers felt that RS was helpful in identifying patients at risk for ED visits or hospitalization. Providers cited self-management skills (health literacy, engagement with care plans, adherence to medications, etc.), availability of support systems and severity of disease as factors that were considered in the risk adjudication process. Providers felt that the computer algorithm did not accurately predict risk among patients with a history of psychological trauma, intimate partner violence, substance use disorders or mental health diagnoses. According to providers, the number of preventable and actionable emergency department (ED) visits and hospital admissions was not always accurately predicted by RS, leading to inappropriate elevation in calculated risk scores. Providers felt that human review/ adjudication is required to predict what patients would benefit from additional clinic resources (e.g., nurse care management)

CONCLUSIONS: Though providers described benefit of RS in terms of identifying those patients at risk for ED utilization or hospitalizations, they felt that RS did not accurately identify severity of disease or social support systems. Human review is required for consideration of the social determinants of health and to identify high need patients that would benefit from additional clinic resources.

PRIMARY CARE PROVIDERS' PERSPECTIVE ON IMPLEMENTING RISK-BASED LUNG CANCER SCREENING FOLLOWING ACADEMIC DETAILEDING

Sarah E. Skurla¹; Julie Lowery¹; Nathan J. Leishman¹; Angie Fagerlin^{1, 3}; Tanner Caverly^{1, 2}. ¹Department of Veterans Affairs, Ann Arbor, MI; ²University of Michigan Medical School, Ann Arbor, MI; ³University of Utah, Salt Lake City, UT. (Control ID #3184252)

BACKGROUND: Tailoring lung cancer screening (LCS) discussions based on individualized lung cancer risk (risk-based screening) is inherently patient-centered and prevents lung cancer mortality while avoiding excessive testing. However, this approach is new to most primary care providers (PCPs). To understand barriers to and facilitators of implementing a provider tool to aid risk-based LCS, we conducted academic detailing and follow-up qualitative interviews with PCPs.

METHODS: We detailed 105 PCPs at 7 VAs from Jun-Oct 2018. Detailing visits focused on the rationale for taking a risk-based approach to LCS and how to use the web-tool with eligible patients to inform risk-based screening discussions. The detailer took notes of PCP feedback during the visit and we conducted follow-up semi-structured phone interviews with 29 PCPs, 2-4 weeks following the visit. Audio recorded interviews lasted ~20 minutes and were transcribed verbatim. We used NVivo v12 to conduct a rapid content analysis and created comprehensive summaries to identify themes/patterns.

RESULTS: During the detailing visit, PCPs expressed major concerns about the lack of organizational direction/support regarding LCS, though many felt the tool seemed useful for selecting appropriate candidates. Of the PCPs completing follow-up interviews, many saw value in the tool's ability to 1) shape clinician feelings about LCS and 2) guide a useful approach to LCS discussions. They also felt the tool enhanced their ability to share information about individualized risk and the pros/cons of screening. However, at follow-up few PCPs (6 of 29) had used the tool with an actual patient. Limited time in clinic was perceived as a key barrier by almost all PCPs. Most PCPs reported needing only 1 to 2

minutes to discuss LCS but voiced frequently not having even 1-2 minutes during a visit, due to patient-specific needs that were higher priority (e.g., acute complaints), or organizational priorities (e.g., performance measures). Even small additions to workflow (e.g., inputting risk factors into the tool) were too time consuming. As well, some PCPs maintained a dichotomous view of the LCS decision (i.e. screen if eligible vs don't screen if not), so they did not see a need for a risk-based approach to LCS. PCPs supported several ideas to overcome barriers. They had firm opinions about cutting tool content substantially, better integrating the tool into the EMR, and automating the risk calculation. Engaging non- PCP providers or patients in data entry and initial tool use could help, but there are concerns it may not fit into team workflows and that only a minority of patients would participate.

CONCLUSIONS: Even when PCPs see value in a risk-based approach to LCS and a tool to support that approach, they have major challenges implementing it in clinic. Future risk-based tools need to better integrate into workflows and help PCPs understand how to prioritize LCS among other competing demands.

PRIMARY CARE SATISFACTION WITH COLLABORATIVE CARE SERVICES: THE ROLES OF CARE MANAGEMENT AND TECHNOLOGY

Lucinda B. Leung^{1, 2}; Alexander S. Young³; Leonie Heyworth^{4, 5}; Danielle Rose²; Susan E. Stockdale²; A. Laurie Graaff⁶; Timothy Dresselhaus^{7, 4}; Lisa V. Rubenstein⁸. ¹UCLA David Geffen School of Medicine & West Los Angles VA Medical Center, Los Angeles, CA; ²VA Greater Los Angeles Healthcare System, Los Angeles, CA; ³VA & UCLA, Los Angeles, CA; ⁴VA San Diego Healthcare System, La Jolla, CA; ⁵Office of Connected Care/Telehealth, Washington, DC, DC; ⁶VISN 22 (VA Desert Pacific Healthcare Network), Gilbert, AZ; ⁷VA San Diego Healthcare System, San Diego, CA; ⁸RAND and UCLA, Medford, OR. (Control ID #3179140)

BACKGROUND: Aiming to improve access to mental health care, collaborative care models embed nurse care managers and mental health specialists to provide services in primary care. A decade after initiation of the Veterans Health Administration's (VA) Primary Care - Mental Health Integration (PC-MHI), representing the nation's largest implementation of such models, we know little about primary care perceptions of these services. Coordination between primary care and mental health specialties is crucial to collaborative care models, and PC-MHI care management and technologies may facilitate specialist communication and urgent care coordination. We examined primary care clinic leader satisfaction with care for various mental and behavioral health conditions and its relationships with key PC-MHI program features - traditional care management and newer information communication technology.

METHODS: This is a cross-sectional key informant organizational survey about PC-MHI among VA primary care clinic leaders (e.g., physicians, nurse practitioners) in Southern California, Arizona, and New Mexico (VA region with the greatest penetration of PC-MHI services) from February to May 2018 (n=65, 94% response rate). The survey assessed primary care clinic leaders' satisfaction with PC-MHI care, care management availability, and sufficiency of PC-MHI information communication technology (telemedicine, electronic referral/consultation, instant messaging). Using Chi² tests and regressions, we examined relationships between PC leaders' satisfaction and PC-MHI features of care management and of information communication technology (3-item scale, =0.81), controlling for clinic size, location, and case-mix.

RESULTS: Primary care clinic leaders were often "very satisfied" with care for target PC-MHI conditions of anxiety (71%) and depression (69%), but not for other conditions (37% alcohol misuse, 19% pain). Availability of PC-MHI care management was significantly associated with satisfactory depression (p=.02) and anxiety

($p=.02$) services. Although PC-MHI information communication technology was rated as only "always sufficient" in <20% of sites, it was positively associated with satisfaction for suicide risk management ($p=.002$). These associations persisted after adjusting for clinic characteristics.

CONCLUSIONS: Primary care clinic leader satisfaction with PC-MHI care for depression and anxiety was generally high, but not for other common behavioral health conditions. Traditional care management was positively associated with satisfaction in treatment of targeted conditions (i.e., depression, anxiety). While not yet universally accessible among VA primary care clinics, newer PC-MHI information communication technologies were positively associated with satisfaction in time-sensitive suicide evaluation. Increasing availability of PC-MHI features (i.e., care management for common conditions, technology for time-sensitive suicide evaluation) may further practice transformation toward model integration.

PRIMARY CARE SOCIAL NETWORKS AND CANCER PREVENTION BEHAVIORS

Jaya Aysola; Chang Xu; Marilyn M. Schapira. University of Pennsylvania, Philadelphia, PA. (Control ID #3185397)

BACKGROUND: Critical interest remains in how health care delivery models can leverage social networks, given the mounting evidence of the influence of social networks on the promotion of cancer prevention behaviors, such as diet and exercise. Yet, there lacks studies on both how to measure and seed social networks in the primary care setting. The objective of this study was twofold: 1) to evaluate the feasibility of collecting social network data from primary care patients and 2) to determine the social network characteristics of primary care patients enrolled in our study.

METHODS: We recruited 48 primary care patients as Egos in our network using both in-person waiting room and telephone recruitment. Patients that agreed to participate were designated egos in our network and scheduled for a telephone-administered survey on healthy behaviors and cancer prevention knowledge. That survey began with name generator questions, where we asked egos to name up to six family members and/or friends (alters) without qualifiers, followed by questions eliciting who attends his/her primary care practice, lives locally, and/or discusses health matters with him/her. Subsequent sampling and recruitment involved snowball sampling to collect data on social networks. We contacted up to two of the six named alters and at least one of the secondary alters (alters' nominated alters), giving preference to those who utilize primary care at the same practice as the ego or at one of the other study sites. A monetary incentive was provided upon completion of the study. We calculated enrollment rates of egos, comparing in-person versus telephone recruitment, as well as alter enrollment rates. We then assessed the density, reciprocity, and transitivity of our social network as well as within ego-networks the degree of homophily of cancer prevention knowledge, obesity, and smoking.

RESULTS: Ego in-person recruitment was more successful than telephone recruitment, with a contact rate of 38% as compared to 4%. Enrollment rates were 57% and 65% were egos and alters, respectively. Study completion rates for egos was 97% and 100% for alters. The mean (SD) age of participants was 51 (17). About 31% of participants had a high-school diploma or less, 42% reported an annual household income of less than 25,000, about 38% had governmental insurance, and about 62% self-identified as black. The edge density of our social network was 0.01, the degree of reciprocity and transitivity was 0.82 and 0.74 respectively. Ego-network homophily varied by attribute.

CONCLUSIONS: We found snowball recruitment and name generator techniques were successful in collecting social network data among primary care patients. This study yields key insights into how organizations can measure primary care patient networks and those network characteristics.

PROGNOSTIC ACCURACY AND DISCORDANCE AMONG PATIENTS, CAREGIVERS, AND PHYSICIANS IN ADVANCED CANCER

kirti malhotra¹; Joshua Fenton¹; Guibo Xing¹; Paul Duberstein²; Ronald Epstein³; Richard L. Kravitz¹. ¹UC Davis, Sacramento, CA; ²U Rochester, Rochester, NY; ³U of Rochester, Rochester, NY. (Control ID #3186638)

BACKGROUND: In caring for patients with advanced cancer, shared clinical decision making relies on common understanding of prognosis among patients, caregivers, and physicians. However, prior studies have shown considerable discordance in prognostic estimates. The purpose of this analysis was to assess and compare the accuracy of two-year prognostic estimates provided by patients, caregivers and oncologists. We also evaluated various factors associated with prognostic accuracy.

METHODS: This is a secondary observational analysis of data obtained from the Values and Options in Cancer Care (VOICE) Study (a cluster Randomized Controlled Trial). The study included 38 oncologists, 263 patients with advanced non-hematologic cancer, and 193 of their caregivers from clinics in Sacramento and Western New York. We evaluated prognostic discrimination and calibration within each group (oncologists, patients, caregivers) using the c-statistic and chi-square statistic respectively. We also computed an index of prognostic accuracy by subtracting the two-year prognosis as predicted by patients, caregivers and oncologists (on a 0, 0.10, 0.25, 0.50, 0.75, 0.90, 1.0 scale) from the vital status at two-years (whether the patient lived two years; yes=1 or no=0 scale). Finally, we constructed multinomial logistic regression models to assess demographic, clinical and attitudinal factors associated with prognostic accuracy.

RESULTS: Oncologists had better prognostic discrimination as compared to both patients ($p=0.001$) and caregivers ($p=0.03$): C-statistics for oncologists, patients, and caregivers were 0.81 [95% CI: 0.76-0.86], 0.62 [95% CI: 0.55-0.68], and 0.72 [95% CI: 0.65-0.78] respectively. Oncologists also had superior calibration; their predictions of two-year survival were similar to actual survival (p -value= 0.17). In contrast, patients' (p -value = 0.0001) and caregivers' (p -value = 0.003) predictions differed significantly from actual survival. Approximately half of patients' and caregivers' predictions (50.0% and 46.0%, respectively) were classified as unduly optimistic while most of oncologist predictions were classified as realistic (62.0%). Non-white race and higher levels of social well-being were associated with over-optimism among patients ($p<0.05$).

CONCLUSIONS: Our findings suggest that oncologists have good discriminatory ability in their two-year survival predictions and their predictions are well-calibrated. In contrast, patients and caregivers have somewhat inferior discriminatory ability and their predictions are poorly calibrated. In addition, patients and caregivers predictions tend to be more optimistic as compared to the oncologists. Various patient factors such as race, ethnicity, and social and existential well-being may play a role in shaping prognostic accuracy. These findings may help general internists play a more effective role in mediating prognostic discussions and interpreting prognostic information for patients with advanced cancer and their families.

PROMOTING SHARED DECISION-MAKING: LEVERAGING THE PHYSICIAN MORAL COMPASS OR IMPROVING THE WORKPLACE?

Loren Saulsberry; Madison Wilson; Monica E. Peek. The University of Chicago, Chicago, IL. (Control ID #3185200)

BACKGROUND: Shared decision-making (SDM), an essential tenet of patient-centered care, has increasingly been promoted by physician organizations and payers. SDM has potential to improve health outcomes, reduce healthcare costs and address health disparities. To date, studies have not compared the relative impact of internal motivation(i.e. physicians' moral compass) and external workplace factors(e.g. population health management(PHM) strategies such as longer physician visits for complex patients) in promoting shared decision-making between patients and their physicians. We evaluate how physicians' internal motivation and features of their clinical environments relate to provider intentions to practice SDM with their patients.

METHODS: Multivariable logistic regressions of a cross-sectional survey of practicing U.S. physicians(n=176) including medical and surgical specialties identified from the American Medical Association(AMA) Physician Masterfile. Primary care physicians were oversampled, and anesthesiologists and radiologists with limited direct patient care were excluded. Surveys from physicians were collected February-July 2018. The main outcome measure was shared decision-making, as defined based on a response option in a clinical vignette. Independent variables included: a) physician personal/moral responsibility to address health disparities and b) the population health management (PHM) resources of the clinical practice (e.g. types of providers, information technology, and patient support tools). Regression analyses were adjusted for physician demographics (e.g. race/ethnicity, gender, age, political affiliation), physician specialty, and clinical practice characteristics which included practice size and practice type(e.g. group/staff model HMO or hospital-based practice). All analyses determined statistical significance based on two-tailed p-values of <0.05.

RESULTS: Physicians' reporting a sense of personal responsibility to address health disparities had a statistically significant association with expressing intentions to engage in SDM behaviors. Overall, physicians' reporting a sense of personal responsibility to address health disparities were more likely than physicians lacking that sense of responsibility to report SDM intentions (OR = 3.10, 95% CI:1.40-6.84, p<0.01). PHM resources within a practice were not associated with SDM intentions.

CONCLUSIONS: A physician's individual sense of responsibility is a strong predictor of provider intent to engage patients in shared decision-making. Clinical environments with an infrastructure including PHM resources alone may not enhance physicians' equal use of SDM across all types of patients. Interventions focused on expanding PHM resources in clinical practice or implementing broader health system changes to address health disparities should identify clinicians with high ratings of internal motivation (i.e. moral compass) as champion physician leaders to help ensure equitable practices, such as SDM, across patient populations.

PROVIDER "HOTSPOTTERS:" INDIVIDUAL RESIDENTS DEMONSTRATE DIFFERENT PATTERNS OF TEST UTILIZATION ACROSS 3 STANDARDIZED CASES

Eli Cahan²; Kathleen Hanley²; Barbara Porter²; Andrew B. Wallach¹; Lisa Altshuler²; Colleen C. Gillespie²; Sondra Zabar². ¹Bellevue Hospital, New York, NY; ²NYU School of Medicine, New York, NY. (Control ID #3185368)

BACKGROUND: Inter-provider variability is a major source of low-value care. The dissemination of clinical practice guidelines (CPGs) has targeted this variability, yet 44% of physicians are non-adherent to CPG. This may be due to factors including exceptionalism and incentive misalignment that present a conflict between comprehensiveness and prudence in work-up. A subset of *super-utilizers* are notable outliers: fewer than 0.5% of physicians account for 10% of healthcare costs. Super-utilizers order labs, request consults, order imaging, and prescribe medications at rates 30%, 140%, 14%, and 25% higher than the general population. We sought to quantify provider-specific low-value test ordering behaviors across three cases.

METHODS: Unannounced standardized patients (USPs) were trained for standardized simulation of three clinical scenarios: a "Well" visit, a chief complaint of "Fatigue," and a diagnosis of "Asthma." USPs were introduced into medicine residents' clinics in a large urban, safety-net hospital. Diagnostic orders were extracted via retrospective chart review. Scenario-specific appropriateness of diagnostic testing was determined by referencing United States Preventative Services Task Force (USPSTF) and specialty society CPGs. "Excessive" tests were those not explicitly indicated for a given scenario in either USPSTF or society CPGs (versus "indicated" tests). "Discretionary" tests were those conditionally indicated, pending patient-specific factors (such as hemoglobin A1C, pending BMI).

RESULTS: One or more excessive tests were ordered in 44%, 22%, and 17% of Well (n=124), Fatigue (n=148), and Asthma (n=148) encounters respectively. Percent of orders that were excessive were 18%, 8%, and 10%,

respectively. On average, 1.3 (+/- 1.7) excessive orders were made. Within each case, rates of excessive ordering were positively correlated with rates of indicated and discretionary ordering, and negatively correlated with rates of omitting indicated tests. For example, in Fatigue, the correlation between excessive and indicated orders was 0.38, between excessive and discretionary orders rates was 0.59, and between excessive and omitted-indicated tests was -0.25 (all p<0.05). A similar, statistically-significant pattern was found for the other two cases. 10 (21%) and 4 (8%) of 48 residents completing all scenarios demonstrated excessive ordering at rates atleast 1 and 2 standard deviations above the mean, respectively.

CONCLUSIONS: Introducing USPs representing clinical scenarios revealed marked inter-provider variability. Positive associations between rates of excessive, discretionary and indicated ordering suggest tendencies for comprehensiveness over prudence. Over one-fifth of residents completing all 3 cases were high-utilizers, and nearly one in ten were super-utilizers. Awareness of provider-level ordering tendencies can guide education and interventions supporting appropriate diagnostic use.

PROVIDER AND PATIENT EXPERIENCES DE-IMPLEMENTING INHALED CORTICOSTEROIDS

Toral J. Parikh^{6, 1}; Krystel Stryczek²; Chris Gillespie³; George Sayre^{6, 1}; Laura Feemster^{6, 1}; Edmunds M. Udris⁶; Barbara Majerczyk⁶; Seppo Rinne^{4, 7}; Renda S. Wiener^{5, 7}; Christian D. Helfrich^{6, 1}; David Au^{6, 1}.

¹University of Washington, Seattle, WA; ²VA Northeast Ohio Healthcare System, Cleveland, OH; ³Dept. of Veterans Affairs, Bedford, MA; ⁴Edith Nourse Rogers Memorial VA, Bedford, MA; ⁵ENRM VA Hospital, Bedford, MA; ⁶VA Puget Sound Healthcare System, Seattle, WA; ⁷Boston University, Boston, MA. (Control ID #3180241)

BACKGROUND: De-implementing medications may present challenges for providers and patients. Little research has assessed specific instances when a medication is discontinued. We sought to understand the experiences of primary care providers (PCP) and patients when de-implementing inhaled corticosteroids (ICS) in patients with mild-to-moderate COPD, in whom ICS are not recommended.

METHODS: We conducted a mixed-methods analysis for a multi-site, provider-randomized quality improvement project testing a proactive pre-visit e-consultation from a pulmonologist recommending stopping the ICS if appropriate. Control and intervention PCPs were interviewed pre-intervention, and intervention PCPs were interviewed post-intervention. Patient interviews were held within 3 months after the clinic visit. We conducted inductive and deductive thematic analysis of the qualitative data. All participating PCPs (n=137 at 13 VHA primary care clinics) received a post-intervention survey. Forty-eight PCPs returned surveys (24 intervention and 24 control, response rate: 35%). We completed 14 pre-intervention interviews; 6 post-intervention interviews; and 6 patient interviews. Post-intervention interviews are ongoing for PCPs and patients.

RESULTS: In pre-intervention interviews, PCPs were reluctant to discontinue an ICS if the patient perceived a benefit: "*Some of my patients have wondered if they truly need to stop something that seems to be working for them.*" PCPs also had misgivings about making a change when the ICS wasn't causing an acute problem, "*deep down there's a little hesitation that if someone is doing well, why rock the boat?*" In post-intervention interviews, PCPs reported patients were receptive to the medication change, especially in the context of potential harm: "*If they don't need the medication, there's not much point in prescribing something that's only going to do them harm...most of my patients were very receptive to that.*" One PCP reported patient reluctance: "*they feel like something is working very well so they don't want to change it, even though they may not have the exact indication for it.*" Patients often reported deferring to their PCPs: "*I just do what the doctor says so they don't yell at me*" or "*whatever the doctors think, because they have more schooling than I've got.*" However, one patient described ICS as "*a security blanket . . . just to have it here in case.*" In post intervention surveys, 54% of PCPs reported having proposed discontinuing or reducing an ICS prescription for a patient in the past 6 months. Of this

group, 90% reported that their patients responded somewhat or very receptively, and 80% discontinued the ICS or switched to another medication. **CONCLUSIONS:** While PCPs were initially concerned with how patients would respond to discontinuing an ICS, post-intervention interviews and surveys suggested patients were receptive. For future de-implementation strategies, it may be possible to use these findings to address provider concerns regarding anticipated patient reactance.

PROVIDER DECISION-MAKING FOR PROSTATE CANCER SCREENING: A QUALITATIVE STUDY

Julian Brunner^{1, 2}; Emmeline Chuang²; Elizabeth M. Yano^{1, 2}; Narissa J. Nonzee^{2, 4}; Jeremy Shelton³. ¹VA Greater Los Angeles Healthcare System, Sepulveda, CA; ²UCLA, Los Angeles, CA; ³VA Greater Los Angeles Healthcare System, Los Angeles, CA; ⁴UCLA Fielding School of Public Health and Jonsson Comprehensive Cancer Center, Los Angeles, CA. (Control ID #3185310)

BACKGROUND: Prostate-specific antigen (PSA) screening remains controversial, and harms resulting from over-diagnosis are common. In the optimal age group (50-69 years) the benefits are contested, and among men over 70, benefits are even less clear. Yet screening persists among men who are unlikely to benefit, and the factors motivating primary care providers' (PCPs') screening decisions remain poorly understood. Our objective was to examine PCP decision-making about prostate cancer screening and explore reasons for potentially inappropriate screening.

METHODS: We conducted semi-structured interviews with 25 PCPs from hospital-based and community-based VA clinics around the greater Los Angeles area. We conducted thematic analysis of interviews with deductive and inductive techniques, using the interview guide as a starting point for coding.

RESULTS: Most PCPs identified age as the primary factor informing their screening decisions. Several consider life expectancy (at any age), and some use an age cutoff but make exceptions for men in exceptional health. Other prominent factors were family history and race. Less-common factors included previous PSA levels, previous PSA trajectories, agent orange exposure, and testosterone supplementation. Many PCPs reported that they discontinue PSA screening at age 70, but this practice was not universal. The most common reason for potentially inappropriate screening was difficulty applying guidelines precisely, despite general familiarity with guideline recommendations - for example, over-relying on age as a proxy for life expectancy, or overestimating the magnitude of a given risk factor in comparison to potential harms. Several PCPs reported ordering screening for patients who demand it, but reported that such demands are rare ("maybe less than 5% does that ever happen"). A small minority of PCPs were distrustful of relevant guidelines, for example, questioning the generalizability of extant research, ("the department of urology here has a fairly conservative approach, so the likelihood that they are going to get unnecessary morbidity is lower than previous studies"). Complete lack of awareness of relevant guidelines was extremely rare. PCPs voiced the most support for guidelines from the United States Preventive Services Task Force, citing its credibility as an unbiased source. A smaller group preferred specialty society guidelines, citing urologists' expertise in prostate cancer.

CONCLUSIONS: Our findings help explain the reasons that PSA screening persists among patients unlikely to benefit. This information is an important precondition for designing interventions to reduce overuse and improve screening decisions. Interventions that help providers weigh competing risk factors may be more effective than interventions that presume a lack of awareness among PCPs, or presume overwhelming patient demand.

PROVIDER FACTOR IMPACTING THE SCREENING FOR HEPATITIS C INFECTION: A QUALITY IMPROVEMENT INITIATIVE

kavya Kelagere Mayigegowda¹; Rinad Tabbalat¹; Kathryn Jobbins². ¹Baystate Medical Center, Springfield, MA; ²Baystate Health, Springfield, MA. (Control ID #3184406)

BACKGROUND: Chronic hepatitis C virus (HCV) is a major cause of liver-related deaths in the United States. The CDC estimates that about 50 % of Americans with HCV infection are unaware of their infection status. Therefore a need exists for increased screening to identify people with unrecognized infections. There is a recent consensus that patients of advanced practitioners and those of female providers receive better preventative care. The aim of our retrospective cohort study was to determine how these factors impact screening for HCV at a community level.

METHODS: Data were extracted from our institution's electronic charts between October 2016 and October 2018. Patients born between 1945-1965 and had at least two visits to our primary care clinic were included. 3200 eligible visits were identified and patients who were already screened for HCV prior to the study period were excluded. A total of 1265 visits met our criteria. Visits were then categorized into resident group, advanced practitioner group and attending group. There were 800 patients in the resident group, 91 in the advanced practitioner group, and 374 in the attending group. These groups were further categorized into male and female providers. Screening for HCV was measured by laboratory testing for HCV antibody.

RESULTS: HCV screening rate for all providers in our clinic is 54%. The screening rate in the advanced practitioner group is higher than the resident group (64% v/s 52% p=0.03). The screening rate in the advanced practitioner group is similar to the attending group (64% v/s 58% p=NS). The screening rate in the overall female provider group is higher than the male provider group (52% v/s 57% p= 0.04). See table 1 for screening rates in different groups further categorized into male and female providers.

CONCLUSIONS: Based on our data, we conclude that female providers and advanced practitioners are more likely to provide screening for HCV infection. These results could be skewed by the fact that most of our advanced practitioners are females. These findings have prompted us to further gather data from our advanced practitioners and female providers on strategies that could be adopted to improve HCV screening throughout our community practice. Furthermore, need exists for identifying physician and patient related barriers to testing for HCV, as the overall HCV screening rate in our clinic is suboptimal.

PROVIDER KNOWLEDGE, ATTITUDES, AND PRACTICE REGARDING CANNABIS: RESULTS FROM A NATIONAL VETERANS HEALTH ADMINISTRATION SURVEY

Devan Kansagara^{4, 1}; Megan O. Iacocca⁴; William Becker²; Matthew J. Bair³; Benjamin J. Morasco⁴. ¹Oregon Health and Science University, Portland, OR; ²VA Connecticut Healthcare System, West Haven, CT; ³Center for Health Information and Communication, Indianapolis, IN; ⁴VA Portland Health Care System, Portland, OR. (Control ID #3170354)

BACKGROUND: Cannabis is increasingly available and used for medical and recreational purposes due to legal changes and broader cultural acceptance. The Veterans Health Administration (VHA) recommends that clinicians be prepared to discuss cannabis with their patients, though they cannot certify medical marijuana use due its classification as a schedule I substance. Clinicians are allowed to make individualized decisions regarding opioid therapy in those also using cannabis. Few studies have assessed provider knowledge, attitudes and practice regarding cannabis.

METHODS: We developed a 47-item survey to assess VHA primary care providers (PCPs)' knowledge, attitudes, and practice regarding patients' use of cannabis. Survey items were derived from: 1) systematic review data, 2) multidisciplinary expert group discussion, and 3) interviews with clinicians and cannabis dispensary staff. We pilot tested draft surveys with clinicians and made modifications. We conducted age- and

gender-adjusted logistic regression analyses to examine the association of cannabis legality in respondents' states with survey responses. The anonymous survey was sent electronically to primary care chiefs in the VHA nationally, who could then distribute locally to PCPs.

RESULTS: We received 263 completed surveys from PCPs in 39 states and the District of Columbia: 47% of respondents were female, 70% white, and the mean age was 50 years; 38% supported legalization of medical cannabis in all states. A substantial minority were very or somewhat uncomfortable with the following: addressing patient questions about cannabis (33%), identifying cannabis use disorder (35%), and talking to patients about recreational cannabis use (25%). There were knowledge gaps among a substantial minority in specific areas including terminology, psychoactive effects of cannabis components, VHA policy, and evidence regarding benefits and harms of cannabis. A majority of respondents (68%) were likely or very likely to taper opioids if urine drug testing was positive for THC. More respondents from states in which cannabis was illegal (OR 4.7, 95% CI 2.2-10.8) or was recreationally illegal (OR 5.7, 95% CI 2.3-10.8), reported being likely or very likely to taper opioids than participants residing in states where cannabis was legal for medical and recreational purposes.

CONCLUSIONS: This is the first survey to assess VHA PCPs' knowledge, attitudes, and practice regarding cannabis. We found many PCPs had knowledge gaps regarding cannabis, and felt uncomfortable discussing key aspects of cannabis use with their patients. PCPs from states in which cannabis was legal for recreational use were less likely than PCPs from non-legal states to taper opioids in patients with urine drug screens positive for THC. These results suggest a need for targeted educational efforts, as well as more robust guidance and evidence regarding management of patients using prescription opioids and cannabis concomitantly.

PROVIDER PERCEPTIONS OF TELEMEDICINE VIDEO VISITS TO HOME IN A VETERAN POPULATION

Joseph N. Martinez²; Laura Samples²; Yodit Beru²; Meghan Rochester²; Anders Chen^{1, 2}; John Geyer^{1, 2}. ¹VA Puget Sound, Seattle, WA; ²University of Washington, Seattle, WA. (Control ID #3183959)

BACKGROUND: To serve the geographically diverse population enrolled in primary care at VA Puget Sound Health Care System providers use several telehealth modalities including remote patient monitoring and mobile health applications. Clinical video telemedicine to home (CVTH) is a new tool offered that allows clinic-based providers to complete synchronous video clinical encounters via a smartphone, computer or VA issued iPad to patients at home. To date, few primary care providers are using CVTH. As part of a telemedicine project in the VA Center of Excellence in Primary Care Education and the University of Washington IM Residency program QI immersion block, a survey about attitudes and barriers of CVTH adoption was designed by Internal Medicine R2s and disseminated to clinicians at Seattle Primary Care Clinic.

METHODS: A 12-question Likert-type multiple choice survey was generated with input from senior clinical leadership, CVTH users from other disciplines and IT personnel. Study participants included faculty MDs and Nurse Practitioners (NPs), NP and Internal Medicine MD residents and Pharmacists. Content domains include respondent's attitudes, perceived barriers and likely patient-use-scenarios with respect to CVTH. All responses were collected electronically and anonymously via REDCap software over a period of 7 days in November 2018.

RESULTS: 45 responses of 85 surveys sent were received (52%) (18 MD/NP faculty, 18 MD and 2 NP residents, 7 Pharmacists). 2 respondents had previously used video telemedicine and 35 had previously used Skype or Facetime. When asked which clinical scenarios were most amenable to CVTH, more than half of respondents were very likely to somewhat likely to use it for depression (69%), tobacco use (84%), chronic pain (67%), hypertension (89%), and diabetes (93%). 69% percent of respondents were very unlikely to somewhat unlikely to use

CVTH on visits heavily dependent on physical exam techniques such as musculoskeletal (MSK) complaints. 84% of respondents somewhat or strongly agreed that internet connection or a patient's technological competence would limit implementation of CVTH. Less than 20% of respondents strongly agreed or somewhat agreed that their own technological competency would be a barrier.

CONCLUSIONS: Limited data exists about provider perceptions regarding primary care telemedicine. Our survey data will help improve adoption of CVTH in primary care. Given respondents concern about using CVTH for MSK related encounters, a training on video physical exam techniques is being developed with input from other professions that have already robustly implemented CVTH. Given respondents concern that Veterans' technological competency would limit incorporation of CVTH, a pre-visit checklist is being developed to certify patient technological familiarity before an initial CVTH primary care visit occurs. Next steps include surveying Veterans to gauge interest of CVTH, identifying administrative barriers and re-assessing provider perception overtime.

PROVIDER PERSPECTIVES ON BARRIERS AND FACILITATORS OF LONG-ACTING REVERSIBLE CONTRACEPTIVE USE IN A LARGE HEALTH SYSTEM

Anna M. Leone¹; Kelly Williams³; Elizabeth C. Swart³; Sonya Borrero¹; Natasha Parekh². ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh Medical Center, Pittsburgh, PA; ³UPMC Center for High-Value Health Care, Pittsburgh, PA. (Control ID #3180705)

BACKGROUND: In August 2012, the Affordable Care Act's contraceptive mandate required insurance plans fully cover at least one contraceptive method type from each of 18 FDA-approved method categories. Though a primary goal of the mandate was to eliminate cost as a barrier to accessing the full range of contraceptive methods including long-acting reversible contraception (LARC) (i.e., intrauterine devices and implants), only 12% of women in the United States utilized LARC methods in 2014. Qualitative interviews were conducted with LARC providers in a large health system in Western Pennsylvania, with nationally comparable rates of LARC usage, to understand practice- and system-based barriers and facilitators to LARC access.

METHODS: We conducted semi-structured interviews with LARC providers who inserted at least three LARCs in 2017. Using claims data, we compiled a list of 107 eligible providers and conducted a total of 30 total interviews. Providers were defined as "high-uptake" if they administered more than 42 LARCs in 2017 (the median) and "low-uptake" if they administered less than 42 LARCs in 2017. Interviews were recorded and transcribed verbatim. Two coders developed a codebook based on an iterative review of transcripts and then applied themes to remaining transcripts, holding regular meetings to adjudicate coding disagreements. Directed content analysis was utilized throughout the analytic process.

RESULTS: Preliminary themes focused primarily on practice-level barriers and facilitators, as well as one system-level barrier. Providers described several practice-level barriers to LARC access, including, (1) policies requiring women to return for a second appointment to complete LARC insertion and (2) policies requiring women to return while menstruating to complete LARC insertion. Providers mentioned practice-level facilitators to LARC access, including, (1) availability of ancillary clinical staff and (2) patient education materials. Time in provider schedules and practice stocking of the LARC method were mentioned as both facilitators and challenges to LARC access, and both were practice-dependent rather than standardized across all offices represented in the sample. Requiring insurance pre-authorization prior to insertion was commonly described as a system-based barrier to LARC access.

CONCLUSIONS: Patient access to LARC methods can be complicated by clinic-level barriers that are heavily practice-dependent, in addition to system-level barriers. These preliminary findings demonstrate heterogeneity across participating providers and practices regarding their LARC provision policies. Results will provide guidance for practice- and system-

level changes that can be implemented to standardize guidelines for LARC provision and reduce practice- and system-level barriers to LARC access. Further analysis will focus on differences in themes between "high-uptake" and "low-uptake" providers and years in practice.

PROVISION OF PREVENTIVE HEALTH SERVICES TO US WOMEN

Shelby McLaughlin-Patel¹; E. Bimla Schwarz². ¹University of California Davis, Sacramento, CA; ²University of California, Davis, Sacramento, CA. (Control ID #3185980)

BACKGROUND: The US Preventive Services Task Force (USPSTF) provides age-specific recommendations regarding a wide range of screening and counseling services. In 2014, the American College of Obstetricians and Gynecologists' Well-Woman Task Force developed age-specific recommendations to guide the care of women during well-woman visits. We assessed alignment between US provision of preventive health services to women and these recommendations.

METHODS: The National Ambulatory Medical Care Survey (NAMCS) collects data from non-federally employed office-based physicians in the United States. In 2015 (the most recently available data), NAMCS assessed provision of 23 preventive health services. We examined provision of these 23 preventive health services to women by age group (18-25, 26-39, 40-50, 51-65, 66-80, 81+ years), whether the provider identified as the patient's primary care provider (PCP), visit type, and clinician training (internal medicine, family medicine, gynecology).

RESULTS: In 2015, NAMCS collected data on 28,322 US ambulatory visits, of which 13,887 were made by women. Of these, 17% were with clinicians who identified as the patient's PCP; 19% were "preventive health" visits. Visits to a clinician who identified as the woman's PCP were not more likely to include preventive health services than visits to other clinicians; visits identified as "preventive health visits" were not more likely to include any preventive services than other visit types. Preventive counseling of any kind (i.e., on diet & nutrition, exercise, weight reduction, tobacco use, prevention, alcohol abuse, substance abuse, prevention of sexually transmitted infections) was documented for less than 10% of visits made by women of any age group. The preventive service most commonly performed was a pelvic exam. Of the 803 visits to Internists, 1303 to family physicians, and 2246 to gynecologists, pelvic exam was documented for 6.5%, 2.8% and 45%, respectively. In contrast, counseling about diet and nutrition was documented for 24% of visits to Internists, 17% of family physicians and 12% of gynecologists. For women aged 18-50, there were 5,598 visits. Of these, 1,247 (78%) were to an ObGyn.

CONCLUSIONS: US women of all ages appear to be receiving preventive health services relatively rarely. Although it is possible that women received preventive services at other visits not documented in the NAMCS survey, few US women make more than 4 visits to their PCP each year. Given the time limitations inherent in current models of primary care, there is a need to prioritize preventive services. More attention should be given to preventive health counseling, with less time spent on pelvic exams for asymptomatic women, as the USPSTF has determined there to be insufficient evidence to support screening pelvic exams of asymptomatic women. Although this is a snapshot of ambulatory visits, the findings from this descriptive study support prior studies and calls for a stronger coordination of care between a woman's PCP and ObGyn.

PROVISION OF UTILITY SHUTOFF-PROTECTION ILLNESS CERTIFICATE LETTERS AT AN URBAN SAFETY-NET HOSPITAL, 2009-2018

Karen E. Lasser^{1, 3}; Heather E. Hsu^{1, 3}; Erin M. Ashe¹; Pablo Buitron de la Vega¹; Ziming Xuan²; Michael Silverstein^{1, 3}. ¹Boston Medical Center, Boston, MA; ²Boston University School of Public Health, Boston, MA; ³Boston University School of Medicine, Boston, MA. (Control ID #3165439)

BACKGROUND: In Massachusetts, utility companies are prohibited from terminating service to low-income households where occupants present a "Utility Shutoff-Protection Illness Certificate" letter confirming that a household member is seriously ill. It is unclear, however, how many patients receive these letters from their medical providers and whether current efforts to screen for health-related social needs are identifying these patients. Our objective was to characterize the provision of such letters at Boston Medical Center, the largest safety-net hospital in New England.

METHODS: Using data extracted from the electronic health record (Logician and Epic), we performed descriptive analyses examining patient demographics and medical comorbidities among all unique adult patients (age >18 years) at Boston Medical Center with a "Utility Shutoff-Protection Illness Certificate" letter signed by a medical provider from 2009-2018. Among patients who received letters within the past year (when screening for health-related social needs was implemented among adults seen in general internal medicine, family medicine, obstetrics-gynecology, the breast center, and the HIV clinic), we examined the proportion who were screened for having difficulty paying utility bills.

RESULTS: 2981 adult patients received a letter over the study period. The mean age of patients was 52 (sd 15.5); 66% were non-Hispanic black, 15% non-Hispanic white, and 5% Hispanic of any race. An additional 12% had missing race data. Over two-thirds of patients were women. Patients most frequently resided in three high-risk Boston neighborhoods: Dorchester (31%), Roxbury (11%), and Mattapan (7%). Most patients spoke English (86%), while 6% spoke Spanish and an additional 5% spoke Haitian Creole. Most patients had government insurance (42% Medicaid, 37% Medicare), while 18% were commercially insured. Patients frequently had significant comorbid medical illness, including congestive heart failure (19%), COPD (48%), and diabetes (41%). Among the 754 patients who received a letter in the past year, only 25% (185) were screened for having difficulty paying utility bills. Among these 185 patients, only 47% (87) screened positive.

CONCLUSIONS: Many patients who receive care at an urban safety-net hospital are at risk for having their utilities shut off, yet current efforts to screen for health-related social needs detect only a fraction of these patients. When a patient presents with a request for a "Utility Shutoff-Protection Illness Certificate" letter, this should be considered a sentinel event. Such an event should trigger referral of a patient to clinic staff who can connect the patient to fuel assistance and other resources.

PSYCHOMETRIC PROPERTIES OF THE ALTARUM CONSUMER ENGAGEMENT (ACE) MEASURE IN PATIENTS WITH PREDIABETES

Yelba Castellon-Lopez¹; Kia Skrine Jeffers¹; O. Kenrik Duru²; Tannaz Moin³; Carol Mangione⁴; Keith Norris²; Gerardo Moreno²; Ron D. Hays². ¹University of California, Los Angeles, Los Angeles, CA; ²UCLA, Los Angeles, CA; ³UCLA/VA Greater Los Angeles, Los Angeles, CA; ⁴David Geffen School of Medicine at UCLA, Los Angeles, CA. (Control ID #3184777)

BACKGROUND: The Prediabetes Informed Decision and Education (PRIDE) study utilized pharmacist-delivered shared decision making to help patients with prediabetes choose lifestyle change, metformin, or both as a diabetes prevention strategy. All PRIDE participants self-administered 12 items from the Altarum Consumer Engagement (ACE-12) measure to assess activation at baseline, 4 months, and 12 months. The aims of this project were to evaluate the psychometric properties of the open-source ACE-12.

METHODS: We used electronic medical record data to identify overweight/obese patients with prediabetes between 18 and 74 years of age. We conducted exploratory factor analysis using polychoric

correlations, and determined the number of factors based on scree plots and the Tucker and Lewis reliability coefficient. We fit graded response models to obtain item characteristic curves (ICC). We assessed construct validity using Cohen's d for correlations (small effect size defined as $r=0.100$; medium effect size $r=0.243$; and large effect size $r=0.371$). We fit a bifactor model to evaluate whether there was support for an overall 12-item ACE score. Analyses were done with SAS, version 9.3 (SAS Institute), and the R Statistical Computing Environment (Vienna, Austria).

RESULTS: Participants ($n=515$) had a median age of 58; 56% were female; 17% Hispanic, 83% non-Hispanic (46% White, 15% African American, 19% Asian/Pacific Islander, 1% Native American, 19% Other). The scree plot and Tucker and Lewis reliability coefficient (0.95) suggested 3 underlying factors: "Commitment to Health"; "Doctor Choice"; and "Learning About Health". Patients with a high school education or lower were less activated on the commitment scale ($r=0.352$, $p=0.002$), choice scale ($r=0.333$, $p=0.008$), and overall ACE score ($r=0.301$, $p=0.011$). Baseline A1c was not correlated with activation. Depressive symptom scores correlated with our revised commitment scale and the overall score. Specifically, those who scored 5 or higher on the PHQ-9 had lower commitment scale scores ($r=0.352$, $p=<0.001$) and lower overall ACE score ($r=0.222$, $p=0.012$). Patient-reported health had a large correlation with patient activation ($r=0.590$, $p=<0.001$). Patients who reported that their health was less than "very good" scored lower on the commitment scale ($r=0.375$, $p=<0.001$) and learning about health ($r=0.266$, $p=<0.001$). The bifactor model provided support for an overall ACE score, though more work needs to be completed in this area.

CONCLUSIONS: Our analyses of the ACE measure in prediabetes suggest it is generally psychometrically sound. This study contributes to the literature by expanding the validity of open-source tools that measure patient engagement, as an alternative to existing proprietary options.

PSYCHOSOCIAL DISTRESS IN ONCOLOGY PATIENTS IN THE SAFETY-NET: IDENTIFYING POPULATIONS AT RISK

Theora B. Cimino¹; Margot Albert¹; Kiana Said²; Leslie Safier²; Anne Kinderman²; Heather Harris². ¹University of California at San Francisco, San Francisco, CA; ²San Francisco General Hospital, San Francisco, CA. (Control ID #3138442)

BACKGROUND: Heightened distress levels can lead to adverse outcomes in cancer patients, including decreased satisfaction with care, poorer adherence to recommended therapy, and diminished quality of life. Studies on distress screening among cancer patients have largely focused on Caucasian, English speaking, and relatively affluent patient populations. The purpose of this study is to examine the prevalence, predictors, and experience of psychosocial distress among cancer patients within a diverse, urban, and multi-lingual safety-net setting and to assess distress level and ability to access supportive resources at follow up.

METHODS: Participants included a cross-sectional sample of cancer patients age 18 at a medical oncology clinic at an urban public hospital, between December 2014 and June 2016, who completed distress screening at their first oncology visit. Distress levels and sources of distress were obtained using a modified version of the National Comprehensive Cancer Network (NCCN) distress thermometer (a 0-10 scale, 10 = extreme distress) and problem list. Demographic data were abstracted by review of medical records. Patients who reported moderate to severe levels of distress were contacted for telephone follow up 1-12 months after initial screening to reassess distress levels and ability to access referred resources.

RESULTS: 200 of 317 eligible patients (63%) completed psychosocial distress screening and were included in the study. Of screened patients, 61% reported clinically significant distress scores. Results from logistic regression analysis indicated that identifying as African-American, having a history of psychiatric illness, and reporting problems with money, worry, sleep, memory or homelessness were associated with higher self-reported psychosocial distress. Cantonese/Mandarin-speaking patients reported lower levels of psychosocial distress compared to other groups. Telephone

follow up was completed for 39 (42% of eligible patients) and showed a decrease in distress scores from a mean of 6.5 at initial screening to 4.5 at follow up. At follow up, patients utilized only 44% of referrals to supportive services made at the initial visit. 54% of patients cited barriers to access - such as lack of knowledge of the referral, not hearing back from the resource, or needing more information - as the reason they did not utilize a particular service.

CONCLUSIONS: Our cohort had a greater prevalence of significant psychosocial distress than most other studied populations, with persistently elevated distress levels and difficulty accessing supportive services at follow-up. Our study identifies groups that may be at higher risk for clinically significant distress and persistent distress, and suggests that closer follow-up and assistance for patients who report high distress levels may be needed.

PURPOSE IN LIFE AND LIFE SATISFACTION MODERATE THE ASSOCIATION BETWEEN MULTIMORBIDITY AND SOCIAL PARTICIPATION AMONG U.S. MIDDLE-AGED AND OLDER ADULTS

Jamie Luster¹; David Ratz²; Melissa Y. Wei^{1, 3}. ¹University of Michigan, Ann Arbor, MI; ²Veterans Affairs Ann Arbor Healthcare System, Ann Arbor, MI; ³Institute for Healthcare Policy and Innovation, University of Michigan, Ann Arbor, MI. (Control ID #3179961)

BACKGROUND: High social participation is associated with improved happiness, health-related quality of life (HRQOL), lower chronic disease incidence, and all-cause mortality. Multimorbidity is associated with low physical and mental HRQOL; one potential mechanism may be through low social participation. We aimed to quantify the association between multimorbidity and social participation and identify potential moderators: purpose in life, and life satisfaction.

METHODS: Participants were noninstitutionalized US adults 51 years of age from the Health and Retirement Study (N=20918). Multimorbidity was quantified through a validated Multimorbidity-Weighted Index (MWI) that weights self-reported chronic conditions by physical functioning. MWI was examined as a time-varying predictor biennially between 2010-2014 and divided into quartiles (lower score indicated lower multimorbidity). Social participation was a continuous composite score of the frequency of participation in 21 activities in 2014 (range 21-147, lower score indicated more frequent participation in more activities). We used multiple linear regression to examine the association between MWI and social participation, adjusting for age, sex, race/ethnicity, education, employment status, household net worth, and marital status. We examined purpose in life (range 1-6, low to high) and life satisfaction (range 1-7, low to high) as effect measure modifiers for the association between MWI and social participation.

RESULTS: The final sample included 7529 participants with complete exposure and outcome data. Participants had a mean MWI of 7.9 (SD 6.5), social participation score of 101.4 (SD 16.1), purpose in life score of 4.5 (SD 1), and life satisfaction score of 5.0 (SD 1.5). The most frequently reported activities were watching television, reading, and using a computer. In the adjusted model, highest MWI quartile participants reported the lowest social participation ($=2.8$, 95%CI=1.8-3.8) compared to those in the lowest MWI quartile, equivalent to participating in 1 less activity weekly. There were significant interactions between MWI and purpose in life ($p=0.004$) and MWI and life satisfaction ($p=0.04$). For all quartiles of MWI, participants with high purpose in life or life satisfaction scores had significantly greater social participation compared to those with low scores. For those in the highest MWI quartile, having high purpose in life or life satisfaction amounted to an additional 1 activity weekly.

CONCLUSIONS: High multimorbidity using a validated MWI is associated with low social participation among middle-aged and older adults. This relationship was modified by both strong purpose in life and high life satisfaction, which each buffered against lower social participation among adults with any degree of multimorbidity. Social

participation is an important measure of HRQOL that is reduced with increased multimorbidity but may be improved by high purpose in life and life satisfaction.

PURSUING THE DIAGNOSTIC ODYSSEY: PATTERNS OF RESIDENT TEST UTILIZATION DIFFER FOR PREVENTIVE VERSUS DIAGNOSTIC WORK-UP

Eli Cahan²; Kathleen Hanley²; Barbara Porter²; Andrew B. Wallach¹; Lisa Altshuler²; Sondra Zabar²; Colleen C. Gillespie². ¹Bellevue Hospital, New York, NY; ²NYU School of Medicine, New York, NY. (Control ID #3185316)

BACKGROUND: Low-value tests, defined as inappropriate for a given clinical scenario, are ordered in one in five clinic visits. Residents tend to over-order diagnostic tests to "minimize uncertainty" of presenting cases, even though these tests are not useful according to Bayesian statistics; a pursuit deemed the "Ulysses syndrome". Simultaneously, evidence suggests residents misuse preventive tests in half of relevant clinical scenarios. We sought to quantify ordering behaviors in urban primary care clinics across three unannounced standardized cases.

METHODS: Unannounced standardized patients (USPs) were trained for standardized simulation of three clinical scenarios: a "Well" visit, a chief complaint of "Fatigue," and a diagnosis of "Asthma." USPs were introduced into medicine residents' clinics in an urban, safety-net hospital. All electronic orders were extracted via chart review. Scenario-specific appropriateness of diagnostic testing was determined by referencing United States Preventive Services Task Force (USPSTF) and society clinical practice guidelines (CPGs). "Preventive" tests (such as lipid panels or hemoglobin A1C) were derived from USPSTF guidelines whereas "Diagnostic" tests (such as pulmonary function testing for Asthma or heterophile antibodies for Fatigue) were from CPGs. "Excessive" tests were those not explicitly indicated for a given scenario in either USPSTF or CPGs (versus "indicated" tests).

RESULTS: Indicated tests were ordered in 29% of Well (124 encounters), 16% of Fatigue (148 encounters), and 12% of Asthma (170 encounters) cases. One or more excessive tests were ordered in 44%, 22%, and 17% of Well, Fatigue, and Asthma encounters respectively. The distribution of indicated and excessive tests for preventive versus diagnostic purposes varied by case: In Well visits, the majority (71%) of excessive testing was in pursuit of a diagnosis, while three-quarters of indicated testing was for preventive purposes. In Fatigue and Asthma visits, the reverse patterns were true: the majority of indicated tests ordered were diagnostic (81% and 68%, respectively) while the majority of excessive tests were preventive (78% and 63%, respectively).

CONCLUSIONS: Introducing USPs to resident clinics revealed that, for patients presenting without a chief complaint (Well visit), residents successfully ordered less than one-third of indicated tests, and over 75% of inappropriately ordered tests pursued a diagnosis. For patients presenting with chief complaints (Fatigue and Asthma), rates of appropriate ordering were even lower (16% and 12%), and tended to overlook preventive care. In these cases, inappropriate tests tended to be ordered for preventive purposes. Awareness of resident mis-utilization of preventive and diagnostic testing in distinct clinical circumstances can guide educational efforts towards evidence-based care and resource stewardship.

QUALITATIVE ANALYSIS OF A SOCIAL DETERMINANTS OF HEALTH (SDH) FOCUSED HOME VISIT CURRICULUM FOR INTERNAL MEDICINE RESIDENTS

Iman Hassan¹; Amy J. Kennedy¹; Flor de Abril Cameron²; Megan E. Hamm²; Thuy Bui²; Carla L. Spagnoletti¹; Maggie K. Benson¹. ¹University of Pittsburgh Medical Center, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA. (Control ID #3186303)

BACKGROUND: Few categorical internal medicine residencies offer curricula on SDH, despite its impact on patient health. We sought to enhance residents' awareness of SDH via a home visit curriculum.

Following a small group session on neighborhood health effects and electronic tools to address SDH, residents identified one of their clinic patients for which they conducted a virtual and physical neighborhood assessment and SDH-focused home visit.

METHODS: To assess curriculum impact, we conducted five 60-min focus groups of 3 to 5 residents within 2 weeks of the home visit. A total 19 residents participated. An independent, trained facilitator guided the discussion with a question script. Sessions were audio-recorded and transcribed. Using the Editing approach, a codebook was developed along with a qualitative expert. Two coders independently applied the codes to all transcripts using ATLAS.ti 8.0. Discrepancies were adjudicated until full agreement reached. Themes were then identified.

RESULTS: (1) Residents reported the curriculum offered a unique, experiential opportunity to see how patients' neighborhood and SDH impact their health. A resident said, "doing a home visit, you get to see it and that makes it really come to the fore-front of your mind, you don't have to imagine, you see it and then you realize 'oh I should be thinking about xy and z'. This is more helpful than someone saying think about social determinants." (2) Residents cited the neighborhood-mapping component of the virtual assessment as applicable to future patients. They said, "The benefit...was to get us thinking about the patient in the context of his surroundings, rather than just in the context of his or her home" and in clinic "actually seeing how far away [the neighborhood] is from the clinic would probably inform my care a little bit better without taking any extra time." (3) Residents felt the curriculum enhanced their conceptualization of SDH and offered concrete tools applicable to other patients. A resident said, "I think this entire exercise was useful in that now I feel like I know some resources better...feeling like I have something to offer them I think will increase the likelihood that I will bring these things up, with anybody." Another said, "I feel that the home visits do give me such a different, a better sense of my patients in general, that now in my clinic after having done these, I do spend so much more time just being like, "Okay what neighborhood do you live in? Do you live in a house, an apartment?...I ask all sorts of weird questions that I didn't used to ask. Just because I do feel like it's helpful to have a better sense of who they are and where they are."

CONCLUSIONS: Our curriculum prompted greater reflection on and engagement with SDH among residents. They valued the experiential nature and identified components applicable to other patients. Neighborhood and home visits, with an emphasis on local resources, can be successfully used to help residents incorporate SDH into clinical care.

QUALITATIVE ASSESSMENT OF TWO APPROACHES TO IMPLEMENTING CLINICAL DECISION SUPPORT

Susan Stork¹; Jonathan Austrian²; Saul Blecker¹. ¹NYU School of Medicine, New York, NY; ²NYU, New York, NY. (Control ID #3186048)

BACKGROUND: Clinical decision support (CDS) systems can be valuable resources in chronic disease management, but provider utilization of these tools and their integration into workflow remains suboptimal. We used a user-centered design approach to build a CDS recommending evidence-based therapy for heart failure in an inpatient setting. We implemented two versions of the CDS: an interruptive (pop-up) alert and a non-interruptive alert displayed in a provider checklist activity. In a prior study, we found that the interruptive alert was more effective than the non-interruptive alert but suffered from a high dismissal rate. The purpose of this study was to understand provider's perceptions of factors impacting CDS utilization following its implementation.

METHODS: We performed a qualitative study following implementation of two versions of a CDS at an academic medical center. We recruited providers who had either version of the CDS triggered in the prior 24 hours and obtained feedback through semi-structured interviews. Interviews were recorded, transcribed, and double-coded. We performed a constant comparative analysis of the transcripts and developed a coding scheme informed by the Five Rights of CDS combined with Proctor's

outcomes for implementation research framework. We recruited participants until thematic saturation was achieved.

RESULTS: Fourteen providers participated in interviews. In general, providers found the CDS triggered for appropriate patients, provided the right information to determine appropriateness of recommendations, and had good usability. At least four providers believed they were not the right person to receive the alert, reporting that they primarily participated in cross-coverage, worked in a setting where these medications were typically contraindicated, or were already fully compliant with evidence-based medications. Providers complained that the interruptive alert led to workflow disruption and that frequently they would "just need to click through all of this." Nonetheless, many providers still preferred the interruptive version of the alert because they were either: 1) unaware of the non-interruptive alert in the checklist; 2) "don't use the provider checklist" where the non-interruptive alert resided; or 3) were unaware of the provider checklist.

CONCLUSIONS: We found that CDS was generally found to be acceptable, although the interruptive version of the alert was limited by disruptions in workflow. The interruptive alert was ultimately more successful as providers were unaware of the existence of the non-interruptive alert. Furthermore, they infrequently used the provider checklist, a native EHR feature for non-interruptive alerts and messages. Our findings suggest that incorporating user-centered design features can lead to success of an interruptive alert. Furthermore, future efforts to implement non-interruptive alerts must incorporate approaches to increase awareness of the alert and encourage changes in workflow to monitor alert lists.

QUALITATIVE STUDY OF PRIMARY CARE PHYSICIANS' REASONS FOR NOT FOLLOWING GERIATRIC CHOOSING WISELY RECOMMENDATIONS

Theresa A. Rowe¹; Tiffany Brown²; Ji Young Lee¹; Stephen Persell³. ¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³Northwestern University, Evanston, IL. (Control ID #3184036)

BACKGROUND: The Choosing Wisely Campaign identifies several areas to reduce unnecessary testing and treatment in older adults seen in primary care. Objective: To examine clinicians' views on the decision to: (1) screen asymptomatic men aged 76 using prostate specific antigen (PSA) (2) order urine studies in women aged 65 years without genitourinary specific symptoms and (3) de-intensify insulin or oral hypoglycemic medications in type 2 diabetes with a hemoglobin A1C <7.0%.

METHODS: Design, Setting, Participants: In this semi-structured interview study, we interviewed primary care physicians caring for adults aged 65 years recruited from primary care clinics within a large academic health system. Main Outcome and Measure: We transcribed the audio-recorded discussions and analyzed the transcripts using standard techniques of qualitative content analysis to identify major themes.

RESULTS: Fourteen participants were interviewed, 57% were women. We identified several themes. First, most clinicians reported knowledge of these recommendations and could state reasons for not ordering these tests or for de-escalating treatment. Second, physicians relied heavily on patient preference when considering a potentially unnecessary test or treatment. This was particularly true for prostate cancer screening. For example, one physician stated, "Some patients are very insistent or expectant that they would want to continue to get testing." Another said, "If I couldn't educate him enough to reason with him then I think I would order it to make sure patient is less anxious." Third, there appeared to be an underestimation of harm associated with potentially unnecessary testing or treatment and potentially over-valuing clinical benefits. Most participants reported the concern of not wanting to miss a diagnosis when deciding whether to order testing, but few clinicians verbalized the harms associated with these tests. For example, clinicians voiced the concern of missing urosepsis or early prostate cancer, but few acknowledged the downsides of identifying a prostate cancer early in an older man with

limited life expectancy or harms associated with using antibiotics for asymptomatic bacteriuria. Fourth, there was an acknowledgment of the lack of time needed to adequately discuss not performing a test like a screening PSA. Finally, clinicians were resistant to change. For example, clinicians articulated not wanting to deescalate medication for diabetes if the patient was doing well, despite understanding the harms associated with over treatment.

CONCLUSIONS: Although the Choosing Wisely campaign provides guidance on reducing over testing and treatment in older adults, clinicians may not follow these recommendations because of underlying psychological drivers. Understanding these drivers and developing approaches to physician behavior change that address these issues may help to improve evidence-based care for older adults.

QUALITY AND SPENDING IN THE FIRST YEAR OF THE POPULATION-BASED PAYMENTS FOR PRIMARY CARE (3PC) SYSTEM IN HAWAII

Amol S. Navathe^{2, 1}; Ezekiel J. Emanuel²; Amelia M. Bond³; Kristin Linn⁴; Kristen L. Caldarella²; Andrea B. Troxel⁵; Jingsan Zhu²; Lin Yang⁶; Shireen E. Matloubieh²; Elizabeth E. Drye⁷; Susannah Bermheim⁷; Emily Oshima Lee⁸; Mark Mugisshi⁸; Kim Takata⁸; Justin Yoshimoto⁸; Isaac Yuen⁸; Sheryl Okamura⁸; Michael Stollar⁸; Jeffrey Tom⁸; Michael Gold⁸; Kevin G. Volpp^{2, 1}. ¹CMC VA Medical Center, Philadelphia, PA; ²Medical Ethics and Health Policy, University of Pennsylvania, Philadelphia, PA; ³Weill Cornell Medical College, Healthcare Policy and Research, New York, NY; ⁴Biostatistics, Epidemiology and Informatics, University of Pennsylvania, Philadelphia, PA; ⁵New York University School of Medicine, New York, NY; ⁶University of Pennsylvania, Philadelphia, PA; ⁷Yale University School of Medicine, New Haven, CT; ⁸Hawaii Medical Service Association, Honolulu, HI. (Control ID #3183125)

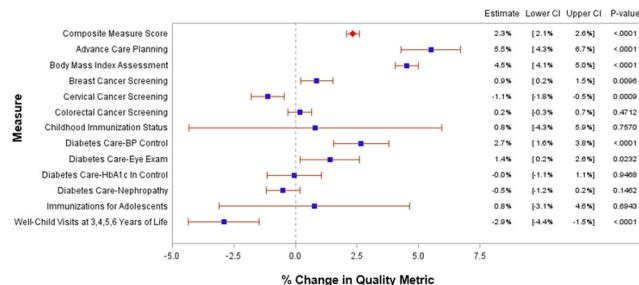

BACKGROUND: In response to modest impact from quality programs, we worked with the Blue Cross Blue Shield of Hawaii to design and implement the Population-based Payments for Primary Care (3PC) system. This system was designed using behavioral economic insights and implemented in a staggered rollout across all Medicare, Medicaid, and commercial members starting in April 2016.

METHODS: We analyzed 2012-2016 claims and quality registry data for 77,225 HMA members attributed to 107 primary care physicians (PCPs) and 4 organizations (POs) participating in the 1st wave of the 3PC and for 222,233 members attributed to 312 PCPs in 14 POs that continued in fee-for service in 2016 but had staggered 3PC start dates thereafter. We used a propensity-weighted, difference-in-differences design to compare risk-adjusted changes in quality, cost, and utilization among patients in the 3PC group to those in the non-3PC group - after confirming parallel pre-intervention trends. We used generalized linear models with an identity link for quality, log link and gamma distribution for cost, and log link and negative binomial distribution for utilization, with standard errors clustered by PCP.

RESULTS: The groups exhibited small baseline differences in demographics, risk scores, and socioeconomic characteristics. Adjusted analysis indicated an association between the 3PC group and increases in quality in 2016 (differential change in risk-standardized quality scores of 2.3 percentage points (p.p.), 95% CI 2.1 to 2.6 p.p., p<0.001). In secondary analyses, performance on 5 quality measures improved, 2 measures worsened, with no changes for six measures (see Figure). There were significant differential reductions in primary care cost (-3.9%, 95% CI -4.8% to -2.9%, p<0.001), but not total cost of care (1.0%, 95% CI -1.3% to 3.4%, p=0.39). Prescription drug cost differentially increased by 20.1% (95% CI 10.2% to 32.5%, p<0.001). Changes in utilization by category were similar in magnitude to changes in cost by category.

CONCLUSIONS: The 3PC was associated with improvements in quality in its first year. Reduction in primary care visits and costs indicate shifts in practice patterns away from visit-based care. This study offers early evidence on the feasibility and effectiveness of shifting to a population-based primary care payment system across commercial, Medicare, and Medicaid

populations in a fragmented market, which may have generalizable implications for other markets with similar characteristics nationwide.

RACE/ETHNICITY AND SEX-RELATED DIFFERENCES IN ANTICOAGULATION IN PATIENTS NEWLY DIAGNOSED WITH ATRIAL FIBRILLATION

Utibe R. Essien^{2, 1}; Jared W. Magnani³; Inmaculada Hernandez⁴; Michael J. Fine²; Walid F. Gellad⁵. ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³University of Pittsburgh Medical Center, Pittsburgh, PA; ⁴University of Pittsburgh, Pittsburgh, PA; ⁵VA Pittsburgh/University of Pittsburgh, Pittsburgh, PA. (Control ID #3183148)

BACKGROUND: Oral anticoagulation (OAC) is associated with stroke risk reduction in patients with atrial fibrillation (AF). Black individuals and women with AF have higher stroke rates, these disparities largely due to lower use and efficacy of traditional warfarin-based OAC in these groups. Less is known about race/ethnicity and sex-related differences in novel direct-acting oral anticoagulant (DOAC) use in patients with AF. Our aim was to compare OAC and DOAC initiation by sex, race, and ethnicity in a real-world, national cohort of patients with AF.

METHODS: We used claims data from a 5% sample of Medicare beneficiaries to identify patients with newly-diagnosed AF between 2013-2014. We excluded those without continuous Medicare enrollment. The primary outcome was the initiation of any OAC (warfarin and DOAC- apixaban, dabigatran, rivaroxaban) after AF diagnosis based on prescription fill data. Among OAC initiators, we compared DOAC vs. warfarin use. We used logistic regression to assess the association between sex, race/ethnicity (white, black, Hispanic) and OAC initiation, adjusting for sociodemographic factors, comorbidities, and stroke risk (CHA₂DS₂-VASc score).

RESULTS: The cohort of 47,952 patients with AF included 17,935 women, 3282 blacks, and 1958 Hispanics. Overall OAC initiation was low (49.2% whites, 48.1% blacks, and 47.5% Hispanics). After adjusting, blacks (odds ratio (OR) 0.84; 95% CI, 0.78-0.91) and Hispanics (OR 0.90; 95% CI, 0.82-0.99) were less likely than whites to initiate any OAC. Women were less likely than men to initiate any OAC, OR 0.59 (95% CI 0.55-0.64). Among OAC initiators, DOAC use was low (35.8% whites, 29.3% blacks, and 40.0% Hispanics). After adjusting, blacks were less likely to initiate DOACs than whites, OR 0.80 (95% CI 0.71-0.90); the odds of DOAC initiation did not differ for Hispanic and white patients; OR 1.10 (95% CI 0.95-1.27). There was no gender difference in DOAC use among OAC initiators, OR 0.98 (95% CI 0.88-1.10).

CONCLUSIONS: In a national cohort of Medicare beneficiaries with newly diagnosed AF, OAC initiation was lower in blacks, Hispanics, and women. Among OAC initiators, blacks were less likely to initiate DOACs, with no differences identified by Hispanic ethnicity or gender. These findings, in a real-world cohort of medically insured patients, show that blacks with AF were less likely to receive novel DOACs - easier to use, potentially safer, and more effective than warfarin in stroke prevention. Identifying modifiable causes of treatment disparities is needed to improve the quality of care for all patients with AF.

RACIAL AND ETHNIC DIFFERENCES IN THE MEDICAL TREATMENT OF OPIOID USE DISORDERS WITHIN THE VA HEALTHCARE SYSTEM FOLLOWING NON-FATAL OPIOID OVERDOSE

Utibe R. Essien^{2, 1}; Florentina Sileanu³; Jane M. Liebschutz⁴; Chester Good²; Xinhua Zhao⁵; Maria K. Mor²; Michael J. Fine²; Walid F. Gellad⁶. ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³VA Pittsburgh, Pittsburgh, PA; ⁴University of Pittsburgh Medical Center, Pittsburgh, PA; ⁵VA Pittsburgh HealthCare System, Pittsburgh, PA; ⁶VA Pittsburgh/University of Pittsburgh, Pittsburgh, PA. (Control ID #3184992)

BACKGROUND: There has been slow adoption of medication-assisted treatment (MAT) in the US, despite substantial morbidity and mortality from opioid misuse and overdose. Even after non-fatal opioid overdose, research shows that few enter addiction treatment, and opioid prescribing patterns frequently are unchanged. Little is known about race/ethnicity differences in care after non-fatal overdose, despite known disparities in opioid prescribing. Our aim was to assess the association of race and ethnicity on receipt of MAT and prescription opioids before and after a non-fatal overdose in a national cohort of patients from the Veterans Health Administration (VA).

METHODS: Using data from the VA Corporate Data Warehouse and Pharmacy Benefits Management Services, we identified all Veterans enrolled in VA from 2011-2013 who had a hospitalization or emergency department visit for non-fatal opioid overdose based on established ICD-9 codes. We excluded patients in hospice care, those with missing or "other" race/ethnicity, and those who died within 7 days of the overdose date. We categorized race/ethnicity as white, black, or Hispanic. Our primary outcomes were: 1) MAT prescription (buprenorphine, naltrexone) or 1 methadone clinic visit within 30 days after overdose, and 2) change in opioid prescription fills within 30 days after overdose from the 30 days before. We used logistic regression, adjusting for age, to test whether MAT receipt after overdose differed by race/ethnicity and used difference-in-differences analyses to test whether change in opioid prescribing after overdose differed by race/ethnicity.

RESULTS: Among 5746 Veterans with a non-fatal overdose, 14.3% were black, 4.2% were Hispanic, and 7.5% women; mean age (SD) was 60.2 (13.7) years. After overdose, 3.3% of Veterans received any MAT, with no difference observed comparing black Veterans to white, adjusted odds ratio (aOR) 1.32, 95% CI 0.90,1.92. Hispanic Veterans were more likely than whites to receive MAT after overdose, aOR 1.87 (95% CI 1.04, 3.37). Before overdose, opioid prescriptions varied by race/ethnicity (65.8% of white Veterans, 59.6% black and 62.9% Hispanic, p value <0.01). After overdose, prescription opioid use decreased significantly to 49.3% in whites (-16.5% absolute difference), 44.5% in blacks (-15.5% absolute difference), and 46.4% in Hispanics (15.9% absolute difference). These decreases in opioid prescription after overdose did not differ between groups (overall p-value 0.88).

CONCLUSIONS: In a national cohort of Veterans with a non-fatal opioid overdose, overall MAT receipt was low with slightly higher rates among Hispanic Veterans compared to whites. After overdose, opioid prescribing decreased across all groups with no difference observed by race /ethnicity. Further examination of racial and ethnic disparities in post-overdose care in contemporary and other real-world patient cohorts is vital to improve quality of care for all patients.

RACIAL DISPARITIES IN CLINICIAN RESPONSES TO PATIENTS' EMOTIONAL CONCERN

Jenny Park¹; Mary Catherine Beach¹; Dingfen Han¹; Somnath Saha². ¹Johns Hopkins University, Baltimore, MD; ²Portland VA Medical Center, Portland, OR. (Control ID #3184737)

BACKGROUND: Prior studies have demonstrated racial differences in the quality of patient-provider communication, which may contribute to disparities in patient experience, treatment adherence, and clinical outcomes. Attending to patients' emotions (e.g., with empathetic statements) is a particularly important aspect of communication, yet few studies have focused on potential disparities in how emotions are handled in clinical encounters. In a previous study of patients newly

enrolled in HIV care, we observed that clinicians were less likely to address the emotional concerns of African American patients compared to whites. In the current study, we aimed to confirm these findings in a separate group of patients already established in HIV care.

METHODS: We enrolled 41 HIV clinicians and 342 English-speaking adult patients receiving HIV care at an urban academic medical center. We audio-recorded one visit for each enrolled patient, transcribed the recordings, and coded them using the Verona Coding Definitions of Emotional Sequences (VR-CoDES). In VR-CoDES, clinician responses to patients' emotional expressions are categorized as (1) explicit vs. non-explicit in terms of addressing the emotion, and (2) providing vs. reducing space for the patient to talk further. Responses that provide space are subdivided into those that are passive (allow the patient to continue speaking with back-channeling such as "uh-huh"), actively explore the issue, or express empathy. Responses that reduce space are subdivided into those that provide information to the patient and those that block the patient from speaking further (e.g. switching topics). We used random intercept multilevel logistic regression, which accounted for clustering of emotional expressions within encounters and of patients within clinicians, to assess associations of race and patterns of emotional talk.

RESULTS: Patients were predominantly African American (76%) or white (21%). Clinicians were mostly white (66%); 15% were African American. Among the 228 patients whose visits included emotional talk, African Americans were less likely to spontaneously express emotion during the visit (OR 0.50; 95% CI 0.29-0.85). Clinicians were more likely to explicitly address emotional concerns expressed by African American patients (OR 1.56; 95% CI 1.11-2.20), but they were less likely to provide space for the patient by offering passive responses (OR 0.56; 95% CI 0.37-0.84), and more likely to block African American patients from talking further about the emotional issue (OR 2.47; 95% CI 1.08-5.67). Clinician race was not associated with response type.

CONCLUSIONS: Our findings confirm those of our prior study, demonstrating that clinicians tend to be less responsive to the emotional concerns of African American patients. Further research should explore reasons for this finding, its potential impact on patient experience and outcomes, and interventions to improve emotional communication across racial/ethnic groups.

RACIAL DISPARITIES IN LOWER EXTREMITY AMPUTATION AMONG PATIENTS WITH PERIPHERAL ARTERIAL DISEASE OR DIABETES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF PUBLISHED STUDIES

Yvette Portilla¹; Binhuan Wang²; Sundar Natarajan³. ¹New York University Langone Medical Center, New York, NY; ²New York University, New York, NY; ³VA New York Harbor Healthcare System, New York City, NY. (Control ID #3162692)

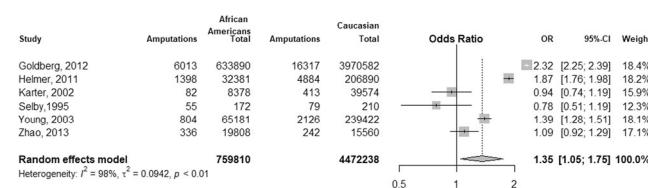

BACKGROUND: Amputation dramatically lowers quality of life and increases risk of mortality in peripheral arterial disease (PAD) or diabetes. Some studies report an increased lower extremity amputation (LEA) risk for black patients compared to white patients, though others report no disparity, particularly in persons with diabetes. We conducted a meta-analysis using PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) guidelines to examine the risk of LEA in black and white adults with PAD and/or diabetes.

METHODS: We systematically searched PubMed and EMBASE databases for cohort or case-cohort studies that included blacks and whites with PAD and/or diabetes and reported risks for LEA. A quality assessment was conducted using the Newcastle-Ottawa Scale (NOS). In addition to presenting the overall risks for amputation attributed to blacks, we conducted a meta-analysis of patients who had a previous amputation and examined the odds that the amputation was primary, defined as an amputation without any previous attempt at

revascularization. A Jackknife sensitivity analysis evaluated the effect of individual articles on the estimate.

RESULTS: After the database search, we identified 570 articles. 13 articles met the inclusion criteria, 9 of which were pooled in the meta-analysis. Among diabetic patients, the unadjusted odds ratio (OR) for black patients (n= 6 studies) receiving a LEA was 1.35 (95%CI, 1.05-1.75) compared to white patients [Figure below]. The Goldberg and Helmer articles had the greatest effect on the pooled estimate. The adjusted risks among black diabetic patients also suggested an increased risk but the large heterogeneity prevented pooling. Similarly, while the risk for LEA among PAD patients could not be quantified, the forest plot indicated an increased risk among blacks. The pooled unadjusted risk for primary amputation (n = 3 studies) among black patients was high (OR, 1.86; 95% CI, 1.35-2.56). Even when using the adjusted OR, the risk was attenuated but remained significant (OR 1.17; 95% CI, 1.09-1.26).

CONCLUSIONS: Black patients with PAD or diabetes are at an increased risk for a LEA as well as for primary amputation. Future studies should evaluate mediators of this disparity and examine ways to eliminate it.

RANDOMIZED CONTROLLED TRIAL OF A RELATIONAL AGENT TO REDUCE RISKY ALCOHOL USE

Steven R. Simon¹; Nicholas Livingston¹; Molly Sawdy¹; Catherine Yeksigian¹; Timothy Bickmore²; Shuo Zhou²; Richard Saitz³; Nancy R. Kressin¹; Amy Rubin¹. ¹VA Boston Healthcare System, Boston, MA; ²Northeastern University, Boston, MA; ³Boston University and Boston Medical Center, Boston, MA. (Control ID #3186360)

BACKGROUND: Risky drinking and alcohol use disorders are present among 20% to 40% of Veterans. Although the efficacy of brief intervention and referral to specialty care for risky drinking is well established, implementation of these approaches often falls short, owing to multiple competing demands on primary care providers (PCPs) and other barriers. A health-information technology (HIT)-based intervention that mimics a live human interaction may offload PCPs and may be more palatable to patients than direct interaction with their provider. We therefore conducted a randomized controlled trial (RCT) of a Relational Agent, a human character on a computer screen that talks with the patient, to reduce risky drinking and promote referral to specialty care.

METHODS: We conducted usability testing to tailor a previously pilot-tested Relational Agent to Veterans' preferences. We enrolled 179 Veterans who screened positive on the Alcohol Use Disorders Identification Test (AUDIT-C) and randomly allocated them to receive the Relational Agent Intervention (RAI) plus Treatment as Usual (TAU) vs. TAU. The RAI consisted of two 15-minute interactive sessions with the Relational Agent, the first occurring at the time of study enrollment, which coincided with a previously scheduled primary care office visit, and the second arranged for one month later. The intervention incorporated Motivational Interviewing, responsibility, empathy, and support of self-efficacy. Telephone follow-up three months after enrollment measured average weekly drinks (primary outcome measure), calculated from the Quick Drink Screen (QDS). We also ascertained referral to specialty care for treatment (secondary outcome measure), which we validated through chart review. **RESULTS:** Veterans in the RAI group (N=90) and in the TAU group (N=89) were similarly distributed with respect to age, sex, race/ethnicity, employment, and presence of VA-recognized disability. At baseline, mean

average weekly drinks (AWD) was lower in the RAI group compared with the TAU group (20.6 vs. 27.2, $p<0.05$). At three months follow-up, mean AWD was 12.4 in the RAI group and 16.0 in the TAU group. Using generalized multilevel mixed modeling to account for baseline differences, the reduction in AWD was similar in the two groups. For the secondary outcome, 26 subjects in RAI (29%) were referred for specialty treatment, compared with 1 in the TAU (1%; $p<0.05$).

CONCLUSIONS: In this primary-care based RCT, a tailored HIT-based intervention engaged Veterans and resulted in increased referrals for specialty treatment of alcohol-use disorder. Relational Agent interventions, now shown to be effective in various health care settings, may be a useful tool to incorporate in primary care; this approach may be tested through other channels, such as web-based platforms and mobile devices, for broader impact on risky drinking and other sensitive health conditions.

RANDOMIZED TRIAL OF GROUP PROBLEM SOLVING FOR CARDIOVASCULAR RISK REDUCTION

David Edelman¹; Laura Wray²; Jason Nieuwsma¹; Cynthia Coffman¹; George L. Jackson¹; Jennifer M. Giersch¹; Margaret Dundon³; Amy S. Jeffreys¹; Rhonda M. Merwin⁴; Karen A. Juntilla¹; Courtney White-Clark¹; Christina L. Vair⁵; Michael Owings²; Amy C. Harris¹; Corrine I. Voils⁶. ¹Durham VA Medical Center, Durham, NC; ²Buffalo VA Medical Center, Buffalo, NY; ³VA National Center for Health Promotion and Disease Prevention, Durham, NC; ⁴Duke University, Durham, NC; ⁵Salisbury VAMC, Salisbury, NC; ⁶University of Wisconsin, Madison, WI. (Control ID #3179399)

BACKGROUND: Shared medical group interventions have been shown to improve outcomes among patients with a common disease or disorder. We sought to determine if a group prevention intervention based on problem-solving theory could reduce cardiovascular risk among patients at risk for cardiovascular disease but without a common risk factor.

METHODS: Patients at 2 VA Medical Centers with at least 5% 10-year risk of a major cardiovascular event as measured by Framingham Risk Score (FRS), and with at least 2% of that risk reversible, were randomized to Group Prevention Coaching (GPC) vs. usual care (UC). GPC comprised 6 group visits among 5-15 patients and 6 individual telephone calls over 18 weeks; the content was derived from Problem Solving Therapy. The group leader, a clinical psychologist, taught patients core skills to improve at least one risk behavior, usually by healthier eating, increasing physical activity, or smoking cessation. Group session content was reinforced with individual telephone calls between each patient and a healthcare coach trained in motivational interviewing. In group visits and individual calls, patients set SMART goals and discussed barriers to achieving these goals along with solutions to these barriers. Primary outcome was FRS; secondary outcomes included the Patient Activation Measure (PAM), range 0-100 points, and the Social Problem Solving Inventory (SPSI), rang 0-139 points. We analyzed differences between GPC and UC at 6 months using an intention-to-treat approach and linear mixed models (LMM), adjusting for group clustering in the GPC arm.

RESULTS: We randomized 202 patients to GPC and 199 to usual care. Mean age was 62.4 years, 10% were women, and 32% were black. Mean 10-year risk of cardiovascular event was 29.2% by FRS; baseline mean PAM and SPSI scores were 60 and 105, respectively. Follow-up rate at 6-months was 62% in GPC and 64% in usual care. GPC patients attended a mean of 3.4 (of 6) group sessions; 43.6% attended 5 or 6 groups, and 14.9% did not attend any. Patients completed a mean of 3.9 (of 6 calls); 57.4% completed 5 or 6 calls, and 14.4% completed no calls. Among GPC patients, 47.7% chose to work on improved eating or weight loss, 17.9% chose to increase physical activity, 27.8% chose to quit smoking, and 6.6% chose another strategy for improving risk (medication adherence or cessation of non-tobacco substance). In the LMM analyses, there was no difference at 6 months between GPC and UC patients in FRS (mean difference 0.7%, 95% CI, -1.4%, 2.8%), PAM score (mean differences 1.3 points, 95% CI -1.3, 3.9), or SPSI (mean difference 1.6 points,

95% CI -0.8, 4.0).

CONCLUSIONS: Our problem-solving-based group prevention intervention failed to improve cardiovascular risk, as measured by Framingham Risk Score (FRS), possibly due to low patient engagement in the intervention.

RAPID ENGAGEMENT OF PATIENTS WITH SUBSTANCE USE DISORDERS THROUGH EXPEDITED TRIAGE (RESET): A JAIL IMPLEMENTATION STUDY

Lello Tesema^{1, 2}; Alia Moore^{1, 2}; Christy Rico²; Michael Hochman^{2, 2}; Stephanie Navarro³; Albert J. Farias^{3, 2}. ¹Los Angeles County Department of Health Services, Los Angeles, CA; ²University of Southern California, Los Angeles, CA; ³University of Southern California Keck School of Medicine, Los Angeles, CA. (Control ID #3165072)

BACKGROUND: Approximately 2/3rd of all inmates in the Los Angeles County (LAC) jail system suffer from substance use disorder, predominantly alcohol-related, and many will experience forced withdrawal following incarceration. Jail facilities often lack standardized methods for identifying patients who are in alcohol withdrawal or at risk of withdrawing, and treatment is commonly de-centralized, resulting in significant mortality and morbidity. In an effort to mitigate adverse outcomes associated with alcohol withdrawal in custody, the LAC jail system established a pilot detoxification (detox) unit and developed a novel triage-to-treatment pathway to identify incoming patients in acute or subacute alcohol withdrawal; treat using the evidence-based CIWA protocol; and refer for Medication Assisted Treatment (MAT). Our study aims to present preliminary clinical effectiveness data for this pathway.

METHODS: This hybrid effectiveness/implementation study uses a quasi-experimental design to compare data from an intervention site (LAC men's jail) and a control site that has not implemented the pathway or detox unit (LAC women's jail). Our study population includes males age 18 who present to jail with a reported alcohol use history and a CIWA score >8 or alcohol consumption within the prior 72 hours; and incarcerated females age 18 who were treated with the CIWA protocol. Variables include time from jail intake to first treatment dose; incidence of uncomplicated withdrawal; and number of referrals for MAT. Preliminary data were collected via chart abstraction of 5% of all patients admitted to the detox unit (intervention site) or treated with CIWA (control site) between June 2018 to November 2018.

RESULTS: Of 454 charts reviewed, 20% of patients were female and 80% were male. There was no statistical difference between intervention and control sites in the mean CIWA score on initial presentation (3.74, 95% CI [3.42, 4.05] versus 3.80, 95% CI [3.20, 4.40]), or the proportion of patients admitted to the detox unit that had one or more CIWA scores >8 (19.6% versus 20.7%), $p=0.48$). However, there was a significant difference between the intervention and control site in the proportion of patients who had 2 or more scores >8 during treatment (9.4% vs 4.3%, $p<0.052$). Ninety-seven percent of patients at the intervention site received an initial treatment dose within 24 hours of intake compared to 71% at the control site ($p<0.001$). Over the 5 month study period, 3 patients from the intervention site were transferred to the hospital for uncomplicated withdrawal, compared to 0 patients from the control site. Thirty-three percent of patients at the control site were referred for MAT, and none from the control site.

CONCLUSIONS: Preliminary results suggest that the pathway effectively expedites identification and treatment of suspected alcohol withdrawal and increases MAT referrals. Future analyses will explore acceptability and feasibility of this pathway.

RATES AND SOCIO-DEMOGRAPHIC CORRELATES OF FOOD INSECURITY AMONG NEW YORK CITY TOBACCO USERS

Christina Wysota¹; Scott E. Sherman^{1, 2}; Elizabeth Vargas¹; Erin S. Rogers². ¹NYU Langone Health, New York, NY; ²VA NY Harbor Healthcare System, New York, NY. (Control ID #3180058)

BACKGROUND: Tobacco remains the leading cause of preventable death and disease in the U.S. Tobacco users are at increased risk of food insecurity, and the co-occurrence of tobacco use and food insecurity may place individuals at especially high risks of poor health. The objective of this study is to identify rates and socio-demographic correlates of food-insecurity among low-income tobacco users in the New York City area.

METHODS: We used baseline survey data from a large randomized controlled trial testing a smoking cessation intervention for smokers living below 200% of the federal poverty level (FPL) to calculate the proportion of smokers experiencing food insecurity, as measured by the USDA 6-item food security model. We used bivariable and multi-variable logistic regression to identify participant factors associated with food insecurity.

RESULTS: Overall, 55% of participants were food insecure, with 27% reporting very high food insecurity. Food insecurity did not significantly differ by gender, race, education, or employment status ($p>.05$). Marital status tended to be a protector against food insecurity. Participants who reported being separated, widowed, or divorced, were more likely to be food insecure than those who reported being married or cohabitating (AOR = 2.24, 95% CI: 1.07-4.72). Additionally, participants who reported being never married had almost three times greater odds of experiencing food insecurity than married or cohabitating participants (AOR = 2.90, 95% CI: 1.40-6.00). Participants who fell below 100% of the FPL were almost two times more likely to experience food insecurity than those with income above the FPL (AOR = 1.95, 95% CI: 1.12-3.40).

CONCLUSIONS: Most low-income tobacco users were experiencing food insecurity. Having been separated, divorced, widowed or never married is a significant predictor of food insecurity. Social networks and removing social isolation may be a protector against food insecurity among this unique sample of low-income NYC smokers. Future interventions which seek to alleviate food insecurity may benefit from targeting the poorest and socially isolated smokers.

RATES OF NO-SHOWS IN AN URBAN PRIMARY CARE CLINIC: DEFINING THE PROBLEM

Elizabeth Pines¹; Patty McGraw³; Vishal Patel¹; Gretchen Rickards²
¹ Christiana Care Health System, Newark, DE; ²Christiania Care Health System, Kennett Square, PA; ³Christiana Care Health Services, Newark, DE. (Control ID #3156677)

BACKGROUND: No-show rates among primary care practices in the United States vary from 5% to 55%.¹ Missed appointments have been associated with increased acute care utilization,^{2,3,4,5} reduced access for other patients,⁶ worse health outcomes,^{2,4} and decreased provider productivity.^{6,7} Continuity clinic is a required component of residency training and missed appointments translate into missed educational opportunities. Few studies have looked at the differences between no-shows among residents and attendings as well as internal medicine (IM) residents and family medicine (FM) residents in the context of primary care. The aim of this study was to examine the association between no-show rates at an urban IM and FM residency continuity clinic based upon provider characteristics (i.e., specialty type and postgraduate year) and appointment type as well as the financial implications no-show appointments have on our clinic.

METHODS: We performed a retrospective chart review of all scheduled appointments from July 1, 2016 to December 4, 2017 of adult patients at an urban IM and FM residency continuity clinic. Data was obtained from a single large regional mid-atlantic health care system. A no-show appointment was defined as an appointment where the patient failed to appear and did not cancel prior to the appointment time. Lost clinic revenue was calculated based on the following billing codes: 99204, 99213, 99214,

99243, 99396. Chi-square test was employed to analyze differences between IM providers and FM providers.

RESULTS: During the study period, there were 58,890 discrete visits. The overall no-show rate was 18.9% (n=11,137), which differed by provider type with IM residents having the highest no-show rate (29.0%) when compared to FM residents (26.3%), IM nurse practitioners (19.1%), and all attendings (17.9%). No-show rate by postgraduate year was significantly different only among categorical IM residents with the later postgraduate years having lower no-show rates ($p < 0.0001$). For both the IM and FM practices, hospital discharge follow-up appointments had the highest no-show rate (34.7% and 38.5%, respectively) while pre-operative appointments had the lowest (9.1% and 17.6%, respectively). The clinic had an estimated \$2,092,260 in lost revenue from no-show appointments during the 18-month study period.

CONCLUSIONS: This study identified significant differences in no-show rates between residents and attendings as well as IM residents and FM residents. Hospital discharge follow-up appointments had the highest no-show rates among all residents. The next step of this project is to develop and implement a survey to assess patient barriers to attending appointments with emphasis on transportation, financial, and scheduling concerns. Subsequently, the chart review and survey data will be combined to develop targeted interventions to reduce no-show rates.

RE-FRAMING OPERATIONAL DECISIONS IN A VALUE-BASED FUTURE: HOW THE LARGEST U.S. PUBLIC HEALTH SYSTEM IS THINKING ABOUT CAPITAL FOR QUALITY IMPROVEMENT INITIATIVES

Hannah B. Jackson; Jeremy O'Connor; Theodore Long. NYC Health + Hospitals, New York, NY. (Control ID #3185494)

BACKGROUND: With ongoing payment reform, there is a continued movement away from fee-for-service to value-based payment (VBP) systems. Often, large hospital systems only account for direct service revenue when deciding whether or not to implement a program. However, with newer payment models such as ACOs as well as Medicaid value-based initiatives, a newer paradigm is emerging that determines program viability based on direct impact on metrics tied to payment. In this exercise, we examined whether it would be feasible to hire new clinical pharmacists to help with medication management for patients with uncontrolled diabetes in five of our outpatient clinics. To assess this, we modeled the capital costs and net income associated with program implementation with and without inclusion of VBPs.

METHODS: We did a cost analysis study to ascertain the feasibility of implementing a diabetes quality improvement (QI) initiative across five clinical sites within the NYC Health + Hospitals public health care system, which cares for a population that is largely uninsured or publicly insured. We defined our population as the number of patients with uncontrolled diabetes (defined as A1c>8.0, "quality metric") at each site. We identified nine metric-linked payment opportunities within our Medicaid managed care plans or linked to state incentive programs and determined the number of our defined population that was eligible for each measure. Next, we calculated the required percent change in a quality metric for the system to be eligible for the VBPs and compared this to the expected impact of our pharmacist program, using conservative estimates from other implementation studies of ambulatory clinical pharmacist integration. With these numbers, we assessed the net operating income/cost with versus without the addition of various potential VBPs.

RESULTS: When we accounted only for direct revenue (without VBPs), we predicted the pharmacy program to generate a net income of \$764,429 in one year. In contrast, with VBPs, we predicted the program to generate up to \$40,195,906 in one year. As an example, in a subset of patients eligible for one of the VBPs, improvements of

2% or 5% in the metric at the targeted sites would result in system-wide improvements of 0.8% or 2.1%, respectively, which would surpass the eligibility threshold for a VBP of \$20,000,000. In another example, if we achieved the goal metric for just 222 more patients, the system would be eligible for a VBP of \$817,950.

CONCLUSIONS: Implementing a diabetes QI program in a value-based era could be associated with a significant increase in revenue in a safety net system - an increase that can be used to support the hiring of additional providers for these programs. Thus, when considering whether or not to implement QI programs, health systems should account for VBP revenue, often tied to small changes in performance, to fully capture the financial impact.

REACH AND EFFECTIVENESS OF VIRTUAL DIABETES PREVENTION PROGRAMS IMPLEMENTED AT NATIONAL SCALE

Ilya Golovaty¹; Sandeep Wadhwa^{2, 3}; Ronli Levi¹; Hilary Seligman¹. ¹University of California San Francisco, San Francisco, CA; ²University of Colorado School of Medicine, Aurora, CO; ³Solera Health, Phoenix, AZ. (Control ID #3180379)

BACKGROUND: Nearly a third of US adults have prediabetes, 5-10% of whom will develop diabetes annually. Sustained weight loss via intensive lifestyle programs based on the Diabetes Prevention Program (DPP) may reduce this risk by half. Virtual DPP, as an alternative to in-person DPP, offers the promise of more rapid scaling but has not been rigorously evaluated. We examined the reach and impact of virtual DPP implemented at national scale.

METHODS: This longitudinal analysis includes data from 20,709 adults referred to 9 virtual DPP providers through a private platform that manages performance-based claims among multiple payers. We included adults age >18 at high risk for diabetes by CDC criteria who were referred to DPP from 2015-2017. The table defines our implementation outcomes (all binary) by categories of *Reach*, *Engagement*, and *Effectiveness*. Multivariable logistic models adjust outcomes for participant (age, gender, race/ethnicity) and setting (state, household income and rurality) characteristics.

RESULTS: Participants had a mean age of 49 and were 74% women and 60% white. The mean BMI was 34 kg/m². *Reach:* In multivariable models, there was an incremental decrease in odds of enrollment by increasing age group (18-44 yo referent, 45-64yo AOR 0.77, [95% CI] 0.73-0.82, >65yo AOR 0.50, 0.45-0.55). Rural participants were slightly more likely than urban participants to enroll (AOR 1.10, 1.00-1.22). *Engagement:* 61% of participants interacted with the program at week 24 among those enrolled. There was an incremental increase in odds of 24-week engagement by increasing age group (18-44 yo referent, 45-64 yo AOR 1.39, 1.28-1.51, >65yo AOR 2.07, 1.76-2.44). *Effectiveness:* 28% of participants achieved >5% weight loss between week 24 and 52 among those who enrolled. Odds of achieving 52-week >5% weight loss increased as age group increased.

CONCLUSIONS: Maintained weight loss with virtual DPP was modest compared to national in-person DPP, but the high reach suggests broad population impact is possible, particularly among younger and more rural participants. As CMS expands reimbursement to performance-based DPP, rigorous examination of virtual platforms will be critical to inform national policy regarding acceptability of virtual DPP as an alternative to in-person DPP.

REASONS FOR NON-VISIT-BASED ANTIBIOTIC PRESCRIBING

Adriana Guzman³; Tiffany Brown³; Ji Young Lee³; Michael A. Fischer¹; Mark W. Friedberg^{2, 4}; Jeffrey A. Linder³. ¹Brigham &

| Implementation Measures | n (%) |
|--|--------------|
| Referred (n=20,709) | |

Women's Hospital, Boston, MA; ²RAND, Boston, MA; ³Northwestern University Feinberg School of Medicine, Chicago, IL;

⁴Brigham and Women's Hospital, Boston, MA. (Control ID #3184238)

BACKGROUND: Non-visit-based antibiotic prescriptions (those that occur outside of an in-office encounter) account for over 20% of all ambulatory antibiotic prescriptions. Little is known about the reasons for non-visit-based antibiotic prescriptions, but the information in electronic health records (EHR) may offer insights. We conducted a retrospective cohort study in a large academic health system to understand reasons for non-visit-based antibiotic prescribing.

METHODS: We queried the EHR of a large, integrated health system to identify all oral, antibacterial antibiotics prescribed from November to December 2018. We excluded antibiotic prescriptions that occurred within 7 days after an in-person office encounter at the prescriber's clinic; to patients with a recently completed or scheduled procedure; to patients with a recent abnormal urine test result; and if there was an infection-related ICD-10 code associated with the antibiotic order. For the remaining non-visit-based antibiotic prescriptions, we randomly sampled a subset and manually reviewed the EHR to identify reasons for the prescription. If no EHR justification could be identified, we contacted clinicians, primarily via email, to complete a survey asking why they prescribed the antibiotic.

RESULTS: During the study, there were 13,686 antibiotic prescriptions, 12,100 (88.4%) were associated with in-person visits at the prescriber's clinic. Of the 1,586 non-visit-based antibiotic prescriptions, 598 (38%) were excluded because of a procedure or abnormal urine result and 159 (10%) had a documented infection-related diagnosis associated with the antibiotic order. After exclusions, 829 (52%) of non-visit-based prescriptions remained unexplained and 741 of these prescriptions were randomly sampled for review. Chart reviewers found an explanation in the EHR for 683 (92%) prescriptions. The most common reasons - not mutually exclusive - were patient reported symptoms (460; 67%), continuation of a previous clinical problem (124; 18%), resulted labs or imaging studies (117; 17%), or upcoming international travel (103; 15%). The most common symptoms documented were cough (170; 37%), sinus symptoms (160; 35%), and urinary symptoms (94; 20%). Continuation of a previous clinical problem was often related to an in-person encounter with a different clinician (88; 71%) and often a response to persistent symptoms, such as cough and sinus symptoms. To date, we have received survey responses from 17 of 45 clinicians. Clinicians' stated reasons include poor documentation (e.g., antibiotic was for a symptom or an infection diagnosis not entered into the EHR), patient travel, or the antibiotic was for a prescriber's family member.

CONCLUSIONS: Non-visit based antibiotic prescribing is generally a response to patient-reported symptoms though it may also occur for a variety of other reasons. A high proportion of non-visit-based antibiotic

prescribing may be inappropriate.

REDEFINING THE ROLE OF PRIMARY CARE PROVIDERS IN CARE OF LIVER TRANSPLANT RECIPIENTS: A CASE STUDY OF THE PRIMARY-SUBSPECIALTY CARE INTERFACE

Amy D. Lu^{1, 2}; Scott D. Rothenberger³; Gary Fischer³; Michael Dunn³; Peggy B. Hasley³. ¹San Francisco VA Medical Center, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³University of Pittsburgh, Pittsburgh, PA. (Control ID #3185093)

BACKGROUND: A major challenge within the primary-subspecialty care interface is defining clear roles and expectations for the relationship between primary care provider (PCP) and subspecialist. As liver transplant recipients (LTRs) are surviving longer, transplant-related metabolic conditions such as, hypertension (HTN), diabetes (DM), dyslipidemia and chronic kidney disease (CKD) have become a major source of non-graft morbidity and mortality. For LTRs, the optimal involvement of PCPs in managing these conditions is unclear. We sought to characterize perceived responsibilities of PCPs and transplant hepatology providers (THP) in the co-management of post-transplant metabolic conditions and determine the effect of PCP perception of responsibility on clinical quality of care in a shared cohort of LTRs.

METHODS: We surveyed PCPs and THPs (surgeons, hepatologists, and physician extenders) regarding the care of post-transplant metabolic conditions in their shared cohort of 56 LTRs >1 year post-transplant (mean 11 years ± 8). PCPs and THPs rated their agreement using a 5-point Likert scale (2=strongly agree to -2=strongly disagree) on statements describing ideal PCP involvement in managing the 4 metabolic conditions, analyzed using two-sample t-tests. PCPs also ranked their level of involvement for each LTR under their care, which was analyzed in relation to clinical outcomes abstracted from chart review including BMI, blood pressure, hemoglobin A1C, screening for retinopathy and CKD, and appropriate statin use via generalized estimating equations for binary data.

RESULTS: A total of 23 THPs (76%) and 32 PCPs (94%) completed the surveys. THPs felt PCPs should have primary responsibility for the management of HTN (1.55±0.80), DM (1.45±0.86), and dyslipidemia (1.27±0.98, p<0.001) in liver transplant recipients. Similarly, PCPs felt that subspecialists should not be primarily responsible for managing HTN (-1.34±0.83), DM (-1.31±0.9), dyslipidemia (-1.47±0.88). Both groups held mixed opinions regarding the management of CKD (PCP 0.59±1.01 vs THP -0.27±1.16) A majority of THPs (57%) reported frequent concern about missed care while 26% PCPs shared the same sentiment. In terms of gaps in quality of care, 51% (20/39) of hypertensive patients in our cohort had uncontrolled HTN, 34% (19/56) did not have regular screening for CKD, and 56% (22/39) where not prescribed statins despite being in a statin benefit group. There were no significant differences in quality of care between PCPs who endorsed 50% responsibility for care compared to those who endorsed <50%.

CONCLUSIONS: Both PCPs and THPs agree that PCPs should assume primary responsibility in the management of HTN, DM, and dyslipidemia in LTRs. Gaps remain in quality for these conditions but were not associated with PCP perception of responsibility. Future research should address barriers to achieving high-quality chronic disease management for transplant recipients and methods to improve communication between PCPs and subspecialists.

REDUCING RESIDENT ADMINISTRATIVE BURDEN USING A REMOTE SCRIBE FOR DISCHARGE SUMMARIES

Shilpa Sharma; Arielle Medford; Daniel Restrepo; Nilay Patel; Aksharananda Rambachan; Kathleen M. Finn. Massachusetts General Hospital, Cambridge, MA. (Control ID #3141270)

BACKGROUND: Administrative burden is widely recognized as detrimental in medical education. The iCOMPARE study found residents

spent 67% of their time on indirect patient care including interacting with the electronic chart. In order to reduce administrative burden, we implemented and evaluated the use of a remote scribe to write initial hospital courses in the Epic discharge module on the general medical service in a large internal medicine residency program.

METHODS: A time motion study was initially performed to assess the amount of time residents spent writing hospital courses. Next, we partnered with IKS Health, a scribe company based in India, whose physicians overnight reviewed resident progress notes and drafted a hospital course, which resident physicians subsequently edited and signed the next morning. To standardize the hospital course, IKS Health was provided with templates along with key findings to include for the 20 most common medical problems. A second time motion study was performed to assess the amount of time residents spent editing the IKS Health hospital courses. Once the program was established, in order to assess quality, we randomized for comparison 200 IKS-written/resident-edited hospital courses and 200 resident only-written hospital courses. Ten resident reviewers were hired, blinded to the writers, and asked to rate the hospital courses on five quality metrics: conciseness, clarity, detail, follow-up, and overall quality. Scores for each metric were averaged for comparison. Each resident evaluator served as their own control by assessing an equal number of intervention and control group hospital courses.

RESULTS: Editing the IKS hospital courses saved an average of 20 minutes per summary when compared to residents writing them in their entirety. The average time for a resident to write a hospital course was 30 min and editing took 10 min. The IKS summaries scored higher on 4 out of 5 quality indicators: clarity, detail, follow-up, and overall. Average scores for IKS written/resident edited vs resident written hospital course were: conciseness 3.06 vs 3.36 (p<0.01), clarity 3.32 vs 3.29 (p=0.88), detail 3.47 vs 3.24 (p=0.02), follow-up 3.37 vs 3.14 (p=0.01), and overall quality 3.34 vs 3.24 (p=0.30).

CONCLUSIONS: These results suggest implementation of a remote scribe for resident hospital courses is feasible and does not affect note quality. Blinded residents rated the IKS hospital courses higher than resident summaries in overall quality and in the subcategories of clarity, detail, and follow-up. With 20 minutes saved per summary this can reduce the administrative burden on residents especially with multiple discharges per day. The ultimate aim of this project was to reduce administrative burden on residents to create more time for residents to spend teaching, learning, and caring for patients. Investigating how residents use the time saved on discharge paperwork will be a compelling next step of the study.

RELATIONSHIP BETWEEN BURNOUT, SPIRITUALITY, AND EMPATHY AMONG PHYSICIANS

Anna-Carson Rimer Uhelski³; Mukta Panda¹; Rehan Qayyum². ¹University of Tennessee, Chattanooga, TN; ²Virginia Commonwealth University, Richmond, Virginia, Richmond, VA; ³University of TN Health Science Center College of Medicine, Memphis, TN. (Control ID #3167101)

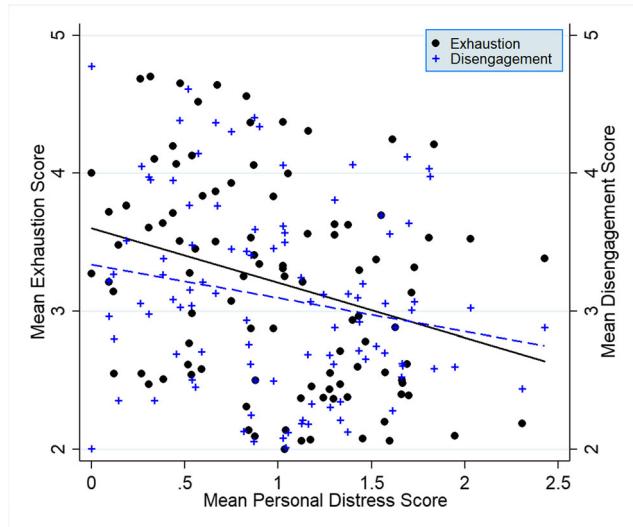

BACKGROUND: Physician burnout has been suggested to be positively associated with degree of spirituality and negatively associated with empathy. Sparse data with mixed results are available. Our objective was to determine if physician burnout is related to spirituality and with empathy.

METHODS: Email survey of faculty physicians, residents, and medical students using a questionnaire about demographic data and three validated tools; burnout tool (Oldenburg Burnout Inventory [OLBI]), spirituality tool (Daily Spiritual Experience Scale [DSES]), empathy tool (Interpersonal Reactivity Index [IRI]). Each item of the survey tools was scored and mean scores were calculated as recommended by survey authors. Linear regression was used to examine the relationship between the two burnout domains of OLBI (exhaustion and disengagement), spirituality, four domains of IRI (perspective taking, fantasy scale, empathetic concern, and personal distress), and total IRI without and with adjustment for age, gender, race, and faculty status.

RESULTS: Of the 101 participants, 47% were females. Mean(SD) exhaustion score was 3.2 (0.7), disengagement 3.0 (0.6), spirituality 2.8 (1.3), and total

IRI score was 2.2 (0.4). In unadjusted and adjusted analyses, we found no association between both domains of OLBI and DSES or total IRI scores. Of the IRI domains, we found a strong but negative association between both domains of OLBI and the personal distress domain but not with other domains. In adjusted models, for each one-point increase in the personal distress domain, OLBI exhaustion score decreased by 0.40 (95% CI = -0.68 to -0.12; P = 0.005) and physician disengagement decreased by 0.20 (95% CI = -0.47 to -0.03; P = 0.047) (Figure).

CONCLUSIONS: We did not find an association between physician burnout and spirituality, total empathy, or empathy domains except for the personal distress domain. Personal distress is a tendency to experience distress and discomfort in response to extreme distress in others. Given that this is a cross sectional study, further research is necessary to establish causality.

RELATIONSHIP BETWEEN FOOD AND HOUSING INSECURITY ON DIABETES SELF-CARE AND QUALITY OF LIFE IN ADULTS WITH DIABETES

Elise Mosley-Johnson¹; Jennifer A. Campbell¹; Rebekah J. Walker¹; Sneha Nagavally²; Leonard E. Egede¹. ¹Medical College of Wisconsin, Milwaukee, WI; ²MCW, Wauwatosa, WI. (Control ID #3186405)

BACKGROUND: Socioeconomic status (SES) has been shown to influence health, however, the aspects of care most strongly associated with social determinants of health related to SES, such as homelessness and food insecurity, are not yet well understood. The aim of this analysis was to examine the relationship between food and housing insecurities, diabetes self-care and quality of life.

METHODS: Data from 16,091 adults with diabetes in the nationally representative Behavioral Risk Factor Surveillance System (BRFSS), years 2014-2015 were used. The primary predictor variables were food insecurity, defined as being worried or stressed in the past 12 months about buying food; and housing insecurity, defined as being worried or stressed about paying rent/mortgage in the past 12 months. The primary outcome variables included quality of life (health status, physically unhealthy days, mentally unhealthy days, days of poor health influencing activities) and diabetes self-care (HbA1c test in past 12 months, receiving diabetes education, daily foot checks, daily blood glucose monitoring, and physical activity in the past month). Unadjusted linear and logistic regression models were run for predictor variable and each outcome variable. Each model was then adjusted for demographics, socioeconomic status, and comorbidity count.

RESULTS: In this sample, 31.4% were food insecure and 38.1% had housing insecurity. Though all outcomes were significant in unadjusted models, after adjustment, housing insecurity was significantly associated with lower health status (-0.22, CI -0.29,-0.15), more physically (1.44, CI 0.39,2.48) and mentally unhealthy days (1.64, CI

0.43,2.85). Food insecurity showed similar relationships (health status: 0.29, CI -0.36,-0.22; physically unhealthy days: 1.16, CI 0.12,2.20) and was associated with more mentally unhealthy days (2.47, CI 1.22,3.72). In regard to diabetes self-care, after adjustment both housing and food insecurity were significantly associated with lower odds of having an eye test (housing OR: 0.78, CI 0.64,0.94; food OR: 0.77, CI 0.63,0.95) and lower odds of physical activity (housing OR 0.86, CI 0.74,0.99; food OR 0.81, CI 0.70, 0.95). Food insecurity was also associated with lower likelihood of having diabetes education (OR 0.79, CI 0.65,0.97). Conversely, housing instability was associated with higher odds of daily foot checks (OR 1.27, CI 1.03; 1.57) and food insecurity was associated with higher odds of daily blood glucose monitoring (OR 1.33, CI 1.05; 1.69).

CONCLUSIONS: In adults with diabetes, housing and food insecurity was associated with lower quality of life and poor self-care behaviors. Diabetes interventions should incorporate the influence of housing and food insecurity on quality of life and obtaining specialty care, such as eye exams. Interventions could also focus on improving opportunities for physical activity.

RELATIONSHIP BETWEEN HOSPITAL READMISSION AND THE USE OF TRANSITIONAL CARE MANAGEMENT (TCM) SERVICES GUIDELINES AT PCP POST-DISCHARGE VISITS

Salina Bakshi^{1, 2}; Jeffrey Schnipper^{2, 2}; Lipika Samal^{2, 2}. ¹Massachusetts General Hospital, Boston, MA; ²Harvard Medical School, Boston, MA. (Control ID #3185895)

BACKGROUND: Transitions of care after hospital discharge are becoming increasingly important under new accountable care organization (ACO) payment models. While many patients are scheduled for follow-up appointments with their primary care physicians (PCPs) after hospital discharge, there are no standard of care guidelines for these often complex visits. Medicare's Transitional Care Management (TCM) billing codes reimburse providers for a set of recommended tasks for post-discharge visits. These tasks include components such as reviewing the discharge summary, reviewing pending diagnostic tests or treatments, providing patient and family education, and arranging for community resources. In this study, we aimed to assess if utilizing these guidelines is associated with reduced hospital readmissions.

METHODS: Patients admitted to medical or surgical units at two hospitals were eligible for the PCORI Transitions Study if they received primary care at one of 18 primary care practices within the Partners ACO. We selected patients in this study who were discharged from the hospital to home between October 2013 and September 2015 and had a post-discharge PCP visit within 14 days. We conducted a nested case control study within the larger trial, comparing readmitted patients with a sample of non-readmitted patients. We examined post-discharge notes for eight TCM elements based on Medicare's TCM Services Guidelines. We calculated a "TCM score," which was the unweighted sum of the number of TCM elements documented during the visit. We then used logistic regression to determine if there was any relationship between TCM score and readmission status. We adjusted the model to account for Elixhauser comorbidity index and number of visits to the PCP office from the prior year.

RESULTS: We reviewed 64 post-discharge visits, representing 34 different physicians and all 18 practices, including 27 readmitted patients and 37 non-readmitted patients. In unadjusted analyses, we found that readmitted patients had *higher* TCM scores on average than non-readmitted patients (4.9 v. 3.5 out of 8, p=0.004). After adjusting for Elixhauser score and visits per year, an increase of 1 point in the TCM score was associated with a 52% increased likelihood of readmission (OR 1.52, 95% CI 1.11,2.07, p=0.009).

CONCLUSIONS: Counterintuitively, we found that patients that

have higher TCM scores and are more likely to be readmitted, even after adjusting for intensity of primary care and medical comorbidities. We hypothesize that we were unable to control for confounding by indication, i.e., that PCPs provide (or at least document) more intensive transitional care for patients whom they believe are at higher risk for readmission. A randomized controlled trial is likely necessary to demonstrate whether TCM activities are effective in improving outcomes after hospital discharge. In addition, other methods of measuring the activities which take place during post-discharge visits may be needed.

RELATIONSHIP BETWEEN MENTAL HEALTH AND OPIOID MISUSE IN PEOPLE LIVING WITH HIV AND CHRONIC PAIN

Emma Richard¹; Ariana G. Pazmino¹; Ana Alicia De La Cruz¹; Chinazo Cunningham¹; Hector R. Perez¹; Chenshu Zhang¹; Yuting Deng^{2, 1}; Joanna L. Starrels¹. ¹Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; ²Montefiore Health System, Bronx, NY. (Control ID #3185372)

BACKGROUND: People living with HIV (PLWH) have a high prevalence of chronic pain and prescription opioid use and misuse. Anxiety, depression, social isolation, and PTSD are common in PLWH and all patients with chronic pain. However, little is known about the relationship between these mental health conditions and prescription opioid misuse in PLWH who have chronic pain.

METHODS: This is a cross-sectional analysis of baseline data from 100 PLWH with chronic pain enrolled in a longitudinal observational study between May 2017 and December 2018. The primary outcome, opioid misuse, was assessed using the Current Opioid Misuse Measure (COMM, scored out of 68, 9 indicates misuse). The COMM assesses self-reported signs and symptoms of intoxication, emotional volatility, poor response to medications, addiction, healthcare use patterns, and problematic medication behavior. Four separate multivariate linear regression models were constructed to examine the relationship between each of 4 mental health variables with opioid misuse: anxiety (Brief Symptom Inventory anxiety subscale, scored out of 24), depression (Center for Epidemiologic Studies Depression Scale, scored out of 30), social isolation (PROMIS measure, scored out of 32), and PTSD (PTSD Checklist-Civilian Version, scored out of 25). Age, race, gender, and whether patients' had 3 opioid prescriptions 21 days apart in 6 months (chronic opioid therapy [COT]) were covariates. A fifth model included all mental health variables.

RESULTS: Of 100 PLWH and chronic pain, 44 were currently prescribed opioids. Of the 44, the mean age was 55, 47.7% were male, 52.3% were African American and 34.1% were Hispanic, and 52.3% were on COT. The mean COMM score was 13 and 65.9% of participants met the threshold for misuse. In separate multivariate linear regression models, anxiety, depression, social isolation, and PTSD were each positively associated with opioid misuse (Table). When all mental health variables were included in the same model, only anxiety remained significantly associated with opioid misuse (adjusted beta=1.08, CI: 0.14-2.03, R²=0.51, p<0.05).

CONCLUSIONS: Among PLWH with chronic pain who are prescribed opioids, anxiety, depression, social isolation, and PTSD were positively associated with opioid misuse using the self-reported COMM, and anxiety appears to be the most robust predictor of opioid misuse as measured by the COMM. However, future investigation is needed to validate which of these conditions are most strongly associated with misuse using objective measures of misuse. These findings suggest that each of these conditions should be evaluated when considering risks of opioids in PLWH with chronic pain.

RELATIONSHIP BETWEEN PHYSICIAN STRESS AND WORK

SATISFACTION AFTER IMPLEMENTING TEAM-BASED PRIMARY CARE FOR COMPLEX PATIENTS: A LONGITUDINAL SURVEY ANALYSIS

Jonathan Weiner; Jodi McCloskey; Connie S. Uratsu; Richard W. Grant. Kaiser Permanente Northern California, Oakland, CA. (Control ID #3178460)

BACKGROUND: Chronic stress from challenging work experiences may contribute to physician burnout. Caring for patients with complex medical and social issues may be one such stressor. We examined changes in self-reported physician stress and work satisfaction after implementing a team-based care management program for complex patients.

METHODS: Primary care physicians (PCPs) from a large integrated care system in Northern California completed surveys just prior to and one year after the implementation of a team-based (PCP, nurse, pharmacist, social worker, coordinator) program designed to support primary care for complex patients. The surveys prompted PCPs to consider their 10-15 most challenging patients and to report levels of stress and overall work satisfaction. The follow-up survey also asked PCPs to rate the helpfulness of eight different program services (e.g. medication management, care coordination, social services, support for elderly issues, and mental health). We compared changes in self-reported stress (decrease, no change, or increase) and changes in work satisfaction (increase vs. decrease or no change) from baseline to follow-up. We also compared changes in stress level and work satisfaction according to higher vs. lower PCP ratings of the helpfulness of care management services. We used logistic regression to control for gender, age, work experience, and baseline PCP panel complexity.

RESULTS: We examined 100 survey pairs for this analysis. Baseline and follow-up surveys were collected 11.9 ± 1.6 months apart (response rate 88%). Two-thirds (65%) of PCPs were women; mean age was 47.8 (± 8.2) years, and mean years' clinical experience was 20 (± 8.6) years. At baseline, 84% of PCPs reported moderate or extreme stress, and 22% were moderately or extremely satisfied with their work experience. After one year, half (49%) of PCPs reported unchanged stress levels, one third (33%) had increased stress levels, and only 18% reported decreased stress. However, over this period, half of PCPs (51%) reported improved work satisfaction. PCPs reporting decreased stress levels were more likely to highly rate help with medication management (aOR 2.44; 95% CI 1.10-5.40) and identifying additional patient resources (2.61; 1.15-5.90) as important benefits of the care management program. PCPs reporting increased satisfaction were more likely to highly rate help with all eight care management services (aORs ranging from 3.14 to 5.75, p<0.01).

CONCLUSIONS: Implementation of a team-based coordinated care program to support primary care of complex patients was associated with increased PCP-reported work satisfaction. However, these changes were insufficient to significantly improve overall PCP work-related stress. These results underscore the challenge of addressing the multi-factorial problem of stress-related PCP burnout.

RELATIONSHIP OF HOME HEALTH CARE AFTER DISCHARGE FROM SKILLED NURSING FACILITIES WITH READMISSION AFTER HEART FAILURE HOSPITALIZATION

Himali Weerahandi¹; Haikun Bao⁷; Jeph Herrin²; Kumar Dharmarajan³; Joseph S. Ross⁴; Simon Jones⁵; Leora I. Horwitz⁶. ¹NYU Langone, New York, NY; ²Yale University School of Medicine, Charlottesville, VA; ³Clover Health, Jersey City, NJ; ⁴Yale University School of Medicine, Woodbridge, CT; ⁵NYU, NY, NY; ⁶NYU School of Medicine, New York, NY; ⁷Yale University, New Haven, CT. (Control ID #3160011)

BACKGROUND: Discharge to skilled nursing facilities (SNF) is common in patients with heart failure (HF). The goal of a SNF stay is to improve functional status to allow patients to return home safely. However, the second transition from SNF to home may also be risky. Here, we examine the association between receipt of home health care (HHC) and readmission risk among patients discharged from SNF to home following HF hospitalization.

METHODS: We examined all Medicare fee-for-service beneficiaries 65 and older admitted 2012-2015 with a HF diagnosis discharged to SNF then subsequently discharged home. The primary outcome was unplanned readmission within 30 days of SNF to home discharge, using CMS's HF readmission methodology. We plotted time to readmission with Kaplan-Meier curves and compared these groups with a log-rank test. Then, we compared time to readmission using an adjusted Cox model; this model included a frailty term to account for correlation of patient outcome by SNF.

RESULTS: There were 67,585 HF hospitalizations discharged to SNF and subsequently discharged home; 13,257 (19.6%) were discharged with HHC, 54,328 (80.4%) without. Patients discharged home from SNF with HHC had lower 30-day readmission rates than patients discharged without HHC (22.8% vs. 24.5%, p<0.0001). Kaplan-Meier curves demonstrated that patients discharged home from SNF with HHC have a longer unadjusted time to readmission. Of those readmitted within 30 days, median time to readmission for those discharged home from SNF with HHC was 11 days and 9 days for those discharged home without HHC (p<0.0001). After risk-adjustment, patients discharged home with HHC still had a lower hazard of 30-day readmission.

CONCLUSIONS: Patients who received HHC were less likely to be readmitted within 30 days compared to those discharged home without HHC. This is unexpected as patients discharged with HHC likely have more functional impairments and therefore at higher readmission risk. Since patients requiring a SNF stay after hospital discharge may have additional needs, they may be especially likely to benefit from restorative therapy through HHC; however only about 20% received such services.

RESIDENT PERCEPTIONS OF BUPRENORPHINE-NALOXONE PRESCRIBING POST ADDICTION CLINIC IMPLEMENTATION

Deepa R. Nandiwada¹; Judy Chertok²; Benjamin Larson³; David Lieberman¹; Marc Shalaby⁴. ¹University of Pennsylvania, Ardmore, PA; ²University of Pennsylvania, Philadelphia, PA; ³Lankenau Medical Center, Philadelphia, PA; ⁴Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA. (Control ID #3186020)

BACKGROUND: There have been a growing number of residency buprenorphine-naloxone clinics with the goal that this should become a part of regular chronic care delivery in a primary care practice. The Penn primary-care-focused residency programs (Primary Care Internal Medicine and Family Medicine) have developed buprenorphine-naloxone residency clinics. The goal of this study is to compare the impact on patient perceptions, role and comfort of residents incorporating this into their scope of practice, and likelihood of including this into their clinical practice as attending physicians.

METHODS: Residents participated in at least two half-day clinic sessions, seeing between 6 to 10 patients in a half day. All residents participated in waiver training and had an additional two didactic sessions on the topic. Surveys were provided to primary care residents and family medicine residents between April to June 2018. At this time primary care residents had all participated in 2 sessions of the clinic and were asked to rate changes in attitudes, knowledge, and perceptions post implementation. Family medicine residents had not begun their clinic yet and so baseline data was gathered.

RESULTS: 14 residents participated in the survey. Using a Wilcoxon-rank sum comparison we had significant changes (p<0.01) with a change from Strongly Disagree to Agree in comfort prescribing. Other findings included being more likely to recommend prescribing buprenorphine-naloxone and increased comfort being a PCP for a patient with opioid addiction. Residents strongly agreed that after participation they felt more empathy for this patient population. Finally they felt more empowered to care and enjoyed caring for this patients with addiction (Disagree to Strongly Agree). Key barriers pre implementation identified were lack of mental health care, logistics, and challenging patients.

CONCLUSIONS: While this represents a very limited data set, it shows that residents attitudes, knowledge, and comfort changed significantly post a direct patient care experience with patients actively prescribing buprenorphine naloxone. We are in the process of comparing this data to

the family medicine pre and post data to see if carries across

| Question | Median Pre-Implementation | Median Post Implementation | P value |
|---|---------------------------|----------------------------|---------|
| I am comfortable prescribing: | 1 | 3 | 0.01 |
| I am very likely to recommend starting: | 2 | 4 | 0.01 |
| I know which patients are good candidates | 2 | 4 | 0.01 |
| I am comfortable being the PCP for a patient with opioid addiction | 2 | 3 | 0.01 |
| I enjoy caring for patients on buprenorphine-naloxone | 2.5 | 4 | 0.01 |
| I feel like I made a difference in my patients life by prescribing buprenorphine-naloxone | | 3.58 | |
| I have more empathy for patients with addiction | | 4 | |
| I feel this fits in the role of a PCP | 3 | 4 | 0.01 |
| I feel empowered to care for patients with addiction | 2 | 4 | 0.01 |

RESIDENTS IDENTIFY GAPS IN MEDICAL EDUCATION REGARDING THE OPTIMAL PROCESS FOR OUTPATIENT REFERRALS

Masha J. Slavin¹; Mangala Rajan²; Lisa M. Kern². ¹New York-Presbyterian/Weill Cornell, New York, NY; ²Weill Cornell, New York, NY. (Control ID #3180908)

BACKGROUND: Referrals from one physician to another in the ambulatory setting are routine, happening multiple times a day for any given physician. It is widely acknowledged that referrals should be accompanied by relevant clinical information about the patient being referred. However, previous work has shown that relevant clinical information is often missing at the point of care. Consequences of missing clinical information may include missed or delayed diagnosis, delayed treatment, unnecessary testing, and drug interactions. Whether residents are taught to provide adequate clinical information at the time of referral has not been well studied. Similarly, residents' attitudes toward providing clinical information at the time of referral and their experiences of the consequences of any subsequent missing information are unknown. Therefore, we sought to assess internal medicine residents' attitudes toward and experiences with outpatient referrals.

METHODS: We conducted a cross-sectional survey in October-December 2018 of all internal medicine residents affiliated with a large, urban academic internal medicine residency program. We used a novel survey instrument that included 13 questions about attitudes toward and experiences with outpatient referrals; each question had responses on a 5-point Likert scale. The survey also included 5 demographic questions. We used descriptive statistics to characterize the results.

RESULTS: We received completed surveys from 122 out of 132 residents (92.4% response rate). Thirty-four percent of respondents were interns, 34% in post-graduate year 2, and 31% in post-graduate year 3. While 83% of residents reported that it is "always" important to provide the clinical reason for a referral, only 11% stated that they "always" provide a sufficient amount of clinical information for the consulting provider when making a referral. Forty-eight percent of residents "never" email, message, or call the consulting physician to explain a case beyond using the electronic health record's referral order template. Nine percent of residents "strongly agree" that residency provides sufficient training in knowing when to refer a patient, and 8% "strongly agree" that residency provides sufficient training in what information to provide the consulting physician.

CONCLUSIONS: These results highlight a discrepancy between the amount of information residents believe they should provide at the time of a referral and the amount they actually provide. Many residents felt that they had not received adequate training during residency on when to refer

patients and what clinical information to convey. These results suggest that a formal curriculum is needed during residency on optimal referral processes, especially since trainees are unlikely to receive this education after they finish their training and because the referral habits developed during training will likely be carried forth into their medical careers.

RESTRICTIONS ON PRIMARY CARE ACCESS FOR PATIENTS RECEIVING OPIOIDS

Pooja A. Lagisetty; Nathaniel Healy; Claire Garpestad; Renuka Tipirneni; Amy Bohnert. University of Michigan, Ann Arbor, MI. (Control ID #3184093)

BACKGROUND: New policies, including mandated prescription drug monitoring programs, have achieved an intended reduction of opioid prescribing. However, policies may create barriers that lead physicians to stop prescribing opioids entirely. Patients may thus encounter difficulties finding primary care providers (PCPs) willing to care for them if they take opioids. We aimed to assess provider willingness to accept and continue prescribing opioids to a new patient with pain and to determine if this differs across payer types.

METHODS: We randomly selected 667 Michigan primary care clinics between June-September 2018. Via calls, we surveyed clinics about the number and type of prescribers, insurances accepted, appointment availability, and whether their providers use medications to treat opioid-use disorders (OUD). Clinics accepting new patients with both Medicaid and private insurance were deemed eligible for inclusion and received a second call from a simulated patient, randomized to either having Medicaid or Blue Cross Blue Shield (BCBS) insurance. Research assistants (RAs) posed as the child of an adult woman needing a new primary care appointment. In this script, RAs revealed the patient's health insurance and asked, "Before we get too far, is it okay if my mother takes opioids for pain?" RAs documented each clinic's willingness to provide care. Clinic characteristics were summarized via descriptive statistics. Generalized logistic regression models estimated the odds of new opioid patient acceptance by insurance type, clinic size, and availability of OUD medications.

RESULTS: Of the 667 clinics screened, 194 were eligible for study inclusion (29%). Ninety-four clinics (48%) were randomized to Medicaid and 101 (52%) to BCBS. Of these clinics, 41% stated that their providers would not prescribe opioids to the simulated patient. 42% of clinics were willing to set up an initial appointment. 33 clinics (17%) requested more information prior to making a decision. Compared to single-provider clinics, clinics with >3 providers were more likely (OR 2.99 [95% CI 1.48-6.04]; p=0.002) to accept new patients on opioids. There was no difference in access based upon insurance status (OR 0.92 [95% CI 0.52-1.64]; p=0.78) or whether the clinic offers OUD treatment (OR 1.10 [95% CI 0.45-2.69]; p=0.83).

CONCLUSIONS: Forty-one percent of clinics were not willing to schedule an appointment for a new patient requesting opioids for chronic pain. Insurance type was not related to willingness to accept a new patient on opioids. These findings may reflect clinicians' discomfort with managing opioid therapy for chronic pain or treating patients with OUD. Larger clinics may have more pain and behavioral health resources, making it easier for providers to care for this population. PCP's reluctance to prescribe opioids may have unintended adverse health outcomes, including increased transition to illicit opioid-use and reduced access to treatment for other comorbidities.

RETROSPECTIVE EVALUATION OF RENAL MEDICATION RELATED CLINICAL DECISION SUPPORT (CDS) ALERTS AND OVERRIDES IN THE INPATIENT SETTING POST IMPLEMENTATION OF A COMMERCIAL EHR.

Sonam N. Shah^{1, 2}; Diane L. Seger^{3, 1}; Mary Amato^{1, 2}; David W. Bates^{1, 4}. ¹Brigham and Women's Hospital, Jamaica Plains, MA; ²MCPHS

University, Boston, MA; ³Partners Healthcare System, Wellesley, MA; ⁴Harvard University, Boston, MA. (Control ID #3180151)

BACKGROUND: Preventable adverse drug events (ADEs) are injuries from medications due to errors. One of the most common medication errors is inappropriate dosing for patients with renal insufficiency. Studies suggest about a third of inpatients with renal insufficiency receive incorrect doses of medications that should be dose-adjusted. Given their association with an increase in hospital length of stay, costs, and morbidity and mortality, efforts have been made to reduce ADEs resulting from these dosing errors. Medication-related CDS have been identified as an effective way to reduce ADEs. We analyzed the appropriateness of renal medication dose CDS alert triggers, number of overridden alerts, and the potential harm that is caused.

METHODS: We performed a retrospective evaluation of renal medication dose CDS alerts in the inpatient setting of a large academic medical center from 5/2017 to 4/2018. Included patients had a creatinine above 3.0 and an overridden renal CDS alert trigger (n = 1352). The primary outcome was appropriateness of the alert trigger and overrides assessed by two reviewers. Secondary outcomes included incidence of ADEs that resulted from the overridden alert based on documentation in the patients' medical record.

RESULTS: Of 1369 alert triggers identified that required renal dose adjustments, those involving medications given for diagnostic procedures or not administered to the patient were excluded, leaving 1352 alerts considered relevant for evaluation (98.8%). Of these alert triggers, 83 (6.1%) were considered appropriate and 1269 (93.8%) were considered inappropriate. Override rates for the renal CDS alert triggers was 100%, with 1291 (95.6%) of the overrides of considered appropriate, and 61 (4.44%) considered inappropriate. Appropriate overrides were largely due to the following medications: KCL (51.3%), chlorothiazide (28.6%), aspirin (21.0%), cholecalciferol (19.3%), magnesium oxide (11.1%), and ergocalciferol (10.6%). Inappropriate overrides were largely due to the following medications: duloxetine (16.7%), phenazopyridine (11.7%), fenofibrate (6.67%), cetirizine (6.67%), and alendronate (5.0%). Identification of ADEs potentially associated with inappropriate CDS overrides was uncommon (n = 2). Further analysis is underway to identify if any ADEs occurred for appropriate CDS overrides.

CONCLUSIONS: Nearly all renal medication dose alert triggers were considered inappropriate; thus, the appropriateness of overrides was high. The risk for alert fatigue could be minimized by increasing the specificity and clinical significance of displayed alerts, while decreasing the number of insignificant alerts. Specific recommendations which could help improve the accuracy of these alerts included the differentiation of the dose prescribed, whether the patient is currently receiving hemodialysis, and patient specific factors such as ordered monitoring lab values.

RIGHT DIAGNOSIS, WRONG DRUG: ANTIBIOTIC PRESCRIBING PATTERNS FOR ACUTE SINUSITIS IN AN INTERNAL MEDICINE RESIDENT CLINIC

Ryan Kipp¹; Eliana Hempel²; Gregory Caputo²; Thomas W. Abendroth⁴; John van Harskamp³; Nicholas Duca². ¹Penn State College of Medicine, Hershey, PA; ²Penn State Health Milton S. Hershey Medical Center, Hershey, PA; ³Penn State Hershey Medical Center, Hershey, PA; ⁴Penn State Milton S. Hershey Medical Center, Hershey, PA. (Control ID #3185550)

BACKGROUND: Acute rhinosinusitis (ARS) accounts for over 23 million outpatient visits each year. The majority of these infections are viral in etiology, and do not require antibiotic treatment. It is estimated that antibiotics are inappropriately prescribed for patients with ARS in 41% of cases. Inappropriate antibiotic use exposes patients to drug-related adverse events, and promotes bacterial resistance. Though inpatient antibiotic stewardship programs have proved impactful, ambulatory antibiotic stewardship programs are not well documented. As a first step to planning

interventions that will improve ambulatory antibiotic prescribing, this study aims to assess the antibiotic prescribing patterns for acute bacterial rhinosinusitis (ABRS) in an Internal Medicine resident clinic.

METHODS: Three investigators reviewed 102 charts for all encounters between October 1, 2015 and December 31, 2018 in which an ICD-10 code for ABRS was used and an antibiotic was prescribed. Utilizing the Infectious Disease Society of America (IDSA) guidelines, we developed a chart review tool to (1) determine appropriateness of antibiotic prescribing by confirming the diagnosis of ABRS, and (2) assess the appropriateness of the selected antibiotic, dose, and duration.

RESULTS: 96% ($n=98$) met the IDSA criteria for diagnosis of ABRS, reflecting that an antibiotic was appropriately prescribed. Of those cases, only 41% followed IDSA recommendations regarding correct antibiotic selection, dose, and duration ($n=42$). Of the patients with documented beta-lactam antibiotic allergy who were appropriately prescribed an antibiotic ($n=31$), only 55% received a recommended second-line agent ($n=17$). Amongst the cases in which the choice to prescribe an antibiotic was appropriate, azithromycin was the most frequently inappropriately selected antibiotic (26%; $n=25$). In cases in which antibiotic selection was appropriate, incorrect dosage accounted for 12% ($n=7$) of inappropriate prescriptions, and excessive treatment duration accounted for 32% ($n=19$).

CONCLUSIONS: Our study revealed that the decision to prescribe an antibiotic for ABRS was appropriate 96% of the time, demonstrating that residents are often effectively able to identify the signs and symptoms of ABRS. However, residents made errors in selection, dose and/or duration of the antibiotic in 58% of the cases ($n=59$). This suggests that inappropriate antibiotic prescription lies not in the choice to prescribe, but in the details of the prescription. Moreover, only 57% of patients who received a second-line antibiotic had a documented allergy. Together, this data sheds light on the highest yield areas for improvement. Next steps for intervention include development of educational materials and electronic health record-based clinical decision support tools aimed at improving appropriate antibiotic selection.

RISK FACTORS FOR 30-DAY READMISSION AFTER INFECTIVE ENDOCARDITIS USING NATIONWIDE READMISSIONS DATABASE

Anthony T. Kunnumpurath¹; Neal Mehta²; Ron T. Varghese³.

¹White River Health Systems, Batesville, AR; ²White River Health System, Kingsport, TN; ³White River Medical Center, Batesville, AR. (Control ID #3181997)

BACKGROUND: The annual incidence of infective endocarditis, infection of the native/prosthetic cardiac heart valve, endocardial surface and/or implanted cardiac device, has increased from a yearly incidence of 11 to 15 per 100,000 from 2000 to 2011 [1,2]. Infective Endocarditis is associated with considerable in-hospital mortality (20%) and post-initial hospitalization mortality (30%) [1]. Better understanding of the risk factors for readmissions of Infective Endocarditis may help to decrease morbidity and mortality. We sought out to determine the 30-day all-cause readmission rate for adults (age ≥ 18) admitted with Infective Endocarditis and the associated predictors of readmissions.

METHODS: We utilized Agency of Healthcare Research and Quality's (AHRQ) Health Care Utilization Project's (HCUP) 2014 Nationwide Readmission Database which includes 14.9 Million discharges across 22 states accounting for 51.2% of the total U.S. population and 49.3% of all U.S. hospitalizations to identify admissions with a Infective Endocarditis related ICD-9 diagnosis (421.0, 421.1, and 421.9). Applicable admissions were all adults (age ≥ 18) with an index hospitalization discharge between January 1 to November 30, 2014. Patients who died during index admission and

those with missing covariates were excluded. All-cause including Infective Endocarditis readmissions within 30-days of a infective endocarditis associated index admission were analyzed. Statistical analysis was completed with Stata 15 (StataCorp, College Station, TX) with p-values < 0.05 considered statistically significant. A univariate and multivariate analysis of data collected was completed using both odds ratio and chi square test for significance. Predictors for readmission were determined using a multivariate logistic regression model following sequential step-wise elimination of covariates including demographics, comorbidities, hospital characteristics, length of stay (LOS) for index admission, and the modified Elixhauser Comorbidity Index.

RESULTS: A total of 14,705 patients met criteria for inclusion. Of which, there was 3,842 (26.13%) readmissions within 30-days of the index admission. Multivariate analysis showed that the predictors of 30-day readmission were younger age, female, disposition at discharge (other facility or against medical advice), Medicare as payer, length of stay, admission to a medical compared to surgery team, and presence of three comorbidities (complicated diabetes, perivascular disease, and renal failure).

CONCLUSIONS: Greater than 1 in 4 patients discharged after an infective endocarditis admission were readmitted within 30 days. Physician awareness and development of targeted interventions for individuals with risk factors and high-risk for readmissions may help decrease future morbidity and mortality.

ROOM FOR IMPROVEMENT: PRIMARY CARE PHYSICIANS' USE OF EVIDENCE-BASED STRATEGIES TO IMPROVE ADULT IMMUNIZATION

Laura P. Hurley^{1, 4}; Sean T. O'Leary^{2, 4}; Megan C. Lindley⁵; Lori A. Crane^{2, 4}; Jessica R. Cataldi^{2, 4}; Michaela Brtnikova^{2, 4}; Brenda Beaty⁴; Allison Kempe^{3, 4}. ¹Denver Health, Denver, CO; ²University of Colorado Anschutz Medical Campus, Aurora, CO; ³University of Colorado and Children's Hospital Colorado, Aurora, CO; ⁴ACORDS University of Colorado Anschutz Medical campus and Children's Hospital Colorado, Denver, CO; ⁵Centers for Disease Control and Prevention, Atlanta, GA. (Control ID #3178595)

BACKGROUND: Adult immunization rates are low nationally and little is known regarding the use of evidence-based strategies to increase rates by physicians serving adults. Our objectives were to assess among general internists (GIM) and family physicians (FP): 1) strategies used to improve adult immunization rates, and 2) reported use of strategies in 2013 vs. 2015/16.

METHODS: We administered Internet and mail surveys to two distinct nationally representative cross-sectional samples of GIM and FP derived from American College of Physicians and American Academy of Family Physicians memberships in June-October 2013 and December 2015-January 2016. Surveys were sent to 839 and 935 physicians in 2013 and 2015/16, respectively. Chi-square analyses were used to compare responses between the two surveys.

RESULTS: The response rate was 66% in both surveys (553/839 in 2013 and 617/935 in 2015/16); 19 physicians were removed in 2013 and 15 in 2015/16 because they did not administer vaccines. Table 1 shows reported use of strategies to improve vaccination for the two time periods for seasonal influenza and the other recommended adult vaccines. Several strategies, at least for seasonal influenza vaccine, were more commonly reported in the later survey except for written clinical decision support systems (written surveys to determine a patient's vaccine needs).

CONCLUSIONS: With the exception of standing orders for seasonal influenza specifically and electronic CDSS for all adult vaccines, the minority of physicians is using evidence-based strategies to improve adult vaccinations, but use of many strategies has improved over time. Bidirectional interfaces with IIS may facilitate assessing all adult vaccines in an IIS, and that, along with the expanded use of standing orders for all adult

vaccines, may improve adult immunization rates.

SAFETY OF ANTIMOTILITY AGENT USE DURING TREATMENT FOR CLOSTRIDIODES DIFFICILE INFECTION IN MALIGNANT HEMATOLOGY INPATIENTS

IIS=Immunization Information System (a.k.a immunization registry)

CDSS=Clinical Decision Support System

BACKGROUND: Guidelines on the treatment of Clostridioides (Clostridium) difficile infection (CDI) have historically recommended avoiding antimotility agents (AAs) in patients with active CDI based on theoretical concerns that administration of AAs may precipitate serious adverse events such as toxic megacolon in these patients. These recommendations, however, are based on limited and conflicting data. We previously reported preliminary data suggesting the potential safety of AAs in patients with CDI. The current study builds on our prior work using a larger, more robust dataset to describe the use of AAs and adverse gastrointestinal events in patients hospitalized on the malignant hematology service who developed CDI.

METHODS: We used the electronic health record of an 800-bed academic teaching hospital to identify all inpatients on the malignant hematology service from April 21, 2012 through September 21, 2017 with one or more positive *C. difficile* stool toxin assays during their admission. We assessed for administration of AAs (loperamide, atropine/diphenoxylate, or opium) within 14 days after CDI diagnosis as well as for any subsequent adverse gastrointestinal events (toxic megacolon, ileus, or bowel obstruction) during the admission by ICD-10 codes. We then manually reviewed all cases of CDI in which an adverse event occurred to determine whether the event occurred within 72 hours after AA administration. Multivariable logistic regression was used to assess the association of adverse events with AAs, adjusting for the propensity to receive AAs, patient characteristics, and markers of disease severity.

RESULTS: We identified 350 patients with CDI, all but 3 of whom received appropriate antibiotic treatment for CDI. 38% were female. 15% were Asian, 4% were black, and 57% were white. 19% were Hispanic. 13% went to the ICU during admission. Mean age was 52.9 years. Mean length of stay was 26.4 days. AAs were used in 27% of cases - or in 95 patients total - and within 48 hours of CDI diagnosis in 33% of these cases. The risk of adverse events did not differ between patients who received AAs and those who did not (2.1% vs. 2.0%, adjusted odds ratio

0.45 [95% CI: 0.08 - 2.70]). Patients who received AAs had more days of diarrhea (4.94 vs. 2.20, p < 0.001), though this was not significant in the adjusted analysis (relative risk 1.14 [0.94 - 1.37]). There were no significant differences in the number of fluid boluses given, the total volume of IV fluid given, or the number of wound care consults in adjusted or unadjusted analyses.

CONCLUSIONS: AAs were administered to 27% of patients in the first 14 days after CDI diagnosis and were not associated with a significantly increased risk of gastrointestinal adverse events. This evidence suggests that it is safe to use AAs in malignant hematology inpatients who are being treated for CDI, even soon after CDI diagnosis.

SCOPE AND CORRELATES OF CHRONIC NON-CANCER PAIN IN PRIMARY CARE

Alexander Chaitoff; Glen B. Taksler; Anita D. Misra-Hebert; Belinda Udeh; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Control ID #3185076)

BACKGROUND: Up to 100 million adults in the United States (US) suffer from chronic pain. However, prevalence estimates from older national samples may not reflect the population of chronic pain patients in primary care who would be affected by policies aimed at curtailing opioid use. The objective of this study was to identify patient factors correlated with reporting chronic pain during primary care visits.

METHODS: This retrospective study used data extracted from the electronic health record at a large integrated health system in the US. Participants were adults treated between January 2014 and December 2015. Patients with metastatic cancer were excluded. The main outcome measures—self-report pain duration, location, and severity as measured by the numeric ranking scale-10—are routinely documented during primary care visits. Chronic pain was defined as lasting >3 months. Predictor variables included demographics, health insurance status, substance use, and comorbidities. Frequencies were used to describe the scope of chronic non-cancer pain in the cohort. Multivariable regression models were used to assess the patient factors associated with reporting chronic pain.

RESULTS: The dataset included 820,028 visits made by 141,635 patients, 24,127 (17.0%) of whom reported at least one period of chronic pain. Patients with chronic pain had more primary care visits during the study period than those who did not report chronic pain (7.2 vs. 4.6, p<0.001). Pain was most commonly reported in the back (n=7293), the lower extremities (n=7194), and the upper extremities (n=5190). The median pain severity was 6/10 (interquartile range (IQR)=4.0-8.0), and 39% involved a severity 7. Pain differed significantly by location; it highest when reported as generalized and lowest when reported in the breast (p<0.001). In a multivariable model, chronic pain was associated with being female (OR=1.16, 95%CI=1.13-1.20), Black vs. White (OR=1.66, 95%CI=1.59-1.73), older age (per 10 years, OR=1.05, 95%CI=1.03-1.06), lower income (per \$10,000; OR=0.98, 95%CI=0.97-0.99), and being divorced (OR=1.10, 95%CI=1.05-1.16) or married (OR=1.10, 95%CI=1.06-1.14) vs. single. Those with chronic pain were more likely to have Medicare (OR=1.87, 95%CI=1.76-1.99) or Medicaid (OR=1.11, 95%CI=1.07-1.16) vs. private insurance. Certain health behaviors, including being a current smoker vs. never smoker (OR=1.35, 95%CI=1.28-1.41) and illicit drug use (OR=1.24, 95%CI=1.14-1.35), were associated with chronic pain, but any alcohol use was associated with lower odds of reporting chronic pain (OR=0.87, 95%CI=0.84-0.89). Finally, having a mental health comorbidity (OR=1.52, 95%CI=1.48-1.57) or higher Charlson comorbidity index (per point; OR=1.08, 1.07-1.09) was associated with chronic pain.

CONCLUSIONS: In a large health system, nearly one in five primary care patients reported chronic pain. Patients historically subjected to disparities are more likely to have chronic pain and to be affected by policies related to its treatment.

SCREENING FOR IMMIGRATION-RELATED HEALTH CONCERNS IN A FEDERALLY QUALIFIED HEALTH CENTER: A MIXED METHODS STUDY

Elena Byhoff^{1, 5}; Emilia De Marchis²; Sofia Halperin-Goldstein⁵; Laura M. Gottlieb³; Amy LeClair¹; Keith Nokes⁴. ¹Tufts Medical Center, Boston, MA; ²University of California, San Francisco, San Francisco, CA; ³UCSF, San Francisco, CA; ⁴Greater Lawrence Family Medical Center, Lawrence, MA; ⁵Tufts University School of Medicine, Boston, MA. (Control ID #3180137)

BACKGROUND: Changes to the public charge rule may make undocumented immigrants less likely to present for health care or report unmet social needs for fear of losing benefits. Immigration-related concerns can impact health and are an important consideration while caring for an immigrant community. We aim to examine the acceptability of screening for immigration-related health concerns within the context of social risk screening in a Federally Qualified Health Center (FQHC) serving a predominantly immigrant (Central America and Caribbean) patient population.

METHODS: This study used a mixed-methods approach. Participants were randomly screened with one of two social risk screening tools. Both tools asked about housing stability, food security, material hardship and transportation. One tool included a question about "any health or stability concerns related to immigration status." The other tool, developed by the Center for Medicare and Medicaid Innovation, did not include an immigration health question. Patients or caregivers waiting for a non-urgent primary care visit were asked to participate. After completing the social risk assessment, respondents were invited to participate in a 30-minute semi-structured interview. The interview focused on patients' understanding of the screening questions, acceptability and comprehensiveness of the screening tool, and perceptions about appropriateness of social risk screening in a health care setting. Interviews were transcribed, translated, and coded to identify themes. Patients were recruited until thematic saturation was reached. All study activities were conducted in either English or Spanish.

RESULTS: A total of 201 screens were completed (100 included immigration question), and 20 patients (10 in each arm) agreed to an interview. There were no significant differences between groups in age, gender, race/ethnicity, or caregiver status. Of those screened for immigration, 11% reported an immigration-related health or stability concern, with no skipped responses. Interview themes showed high acceptability for immigration-related screening, including specific mentions of heightened political concern, health relevance, and the doctor as a trusted ally. In both arms, interviewees felt that social risk screening generally was acceptable in a clinic setting. Those *not* in the immigration arm mentioned that screening for immigration-related concerns was important. Respondents saw clinics as a "safe space" to discuss immigration concerns in comparison to "government" spaces, like WIC, SNAP, and Medicaid offices.

CONCLUSIONS: Social risk screening is acceptable in an FQHC serving a predominantly immigrant community. Questions about immigration are timely, important, and relevant, and can be considered when implementing social assessments in communities where there are high levels of trust in providers. With proposed changes to public charge, FQHCs may serve as meaningful allies in serving immigrant patients with social risk.

SECURE MESSAGING THROUGH POSITIVELINKS: EXAMINATION OF ELECTRONIC COMMUNICATION IN A CLINIC-AFFILIATED SMARTPHONE APP FOR PATIENTS LIVING WITH HIV

Tabor E. Flickinger; Sabrina Swoger; Marika Grabowski; Karen S. Ingersoll; Rebecca Dillingham. University of Virginia,

Charlottesville, VA. (Control ID #3182989)

BACKGROUND: Keeping patients engaged in care may require provider communication between visits. Electronic patient portals are available, but often underutilized. However, many patients now use smartphones daily and patient-provider messaging using these phones may be a promising option. PositiveLinks (PL) is a clinic-affiliated smartphone-based platform, designed to enhance retention in HIV care and tailored to our socio-economically disadvantaged non-urban population. PL includes a secure messaging feature to connect patients to their HIV care team. Our aim was to analyze messages exchanged between patients, staff, and HIV care providers through PL to determine the usage, content, and function of communication through secure messaging between clinic visits.

METHODS: We examined messages exchanged through PL from November 2017 through January 2018. The initial codebook was developed using an open coding strategy, then applied independently by two coders and refined until excellent reliability was achieved with a kappa statistic of 0.89. Topic codes categorized messages as app-related or care-related, which could be medical or social. Function codes categorized messages by their purpose of information exchange or rapport-building. Qualitative analysis was performed using Dedoose software with descriptive statistics of code frequencies and code co-occurrence.

RESULTS: Of the 1474 PL messages analyzed, 44% were sent by PL staff, 38% by patients, and 18% by providers, while 61% were received by patients, 22% by providers, and 17% by PL staff. Message topics included app-related (57.6%), medical care (34.3%), and social concerns (12.4%). App-related messages addressed technical difficulties, software updates, or coordinating phone payments. Medical messages included information, medications, appointments, outreach, and care coordination for physical and mental health. Social messages related to insurance, transportation, housing, food, utilities, disability, finances, and work. Function coding showed that 87.3% of messages contained information exchange and 33.8% contained rapport-building. Information exchange messages were utilitarian in nature while rapport-building messages included psychosocial components, such as addressing emotions, offering thanks or appreciation, or providing personal content beyond information-sharing. Messages sent by providers were most likely to contain rapport-building at 54.8%.

CONCLUSIONS: PL messaging was used to address medical and social needs in a vulnerable population and to connect patients with care providers. Electronic communication offers an opportunity to exchange practical information and also to strengthen patient-provider relationships. Next steps include further analysis of socioemotional tone in the messaging and impact on engagement in care, provider attitudes, and patient outcomes. Secure messaging through a clinic-affiliated smartphone platform could enhance patient-centered care between clinical visits.

SEEING I TO EYE TOGETHER: AN EDUCATIONAL CAMPAIGN DESIGNED TO IMPROVE PHYSICIAN-PATIENT COMMUNICATION AMONG INTERNAL MEDICINE RESIDENTS

Robin Ortiz³; Meron Hirpa¹; Aparna Sajja¹; Jesse McDermit¹; Alison Agrawal¹; Megan Tschudy³; Stephen Berry²; Kimiyoshi Kobayashi¹.

¹Johns Hopkins Hospital, Baltimore, MD; ²Johns Hopkins School of Medicine, Baltimore, MD; ³Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3175978)

BACKGROUND: Sitting at the bedside improves patients' perception of their interactions with their physicians and improves patient satisfaction and outcomes. Despite these data, prior work shows that medicine interns sit during only 9% of observed physician-patient interactions. We aimed to design an educational curriculum to improve physician-patient communication and decrease resistance to sitting at the bedside.

METHODS: A needs assessment among Internal Medicine residents at an urban academic medical center was conducted anonymously using an

electronic survey. The survey was designed to assess knowledge gaps in residents' perceptions and self-reported behaviors around sitting during inpatient encounters. Informed by survey results, an evidence-based educational campaign was designed to address the observed deficits in resident knowledge regarding time and communication in physician-patient encounters.

RESULTS: The needs assessment yielded 96 responses of 151 residents surveyed (64% response rate). Residents who reported spending enough time at the bedside were also likely to report that their patients could identify them as their doctor ($r_s=0.28$, $p=0.006$). The majority of residents (63%), however, felt they rarely or never spent enough time at bedside. Although 69% of respondents felt that sitting during an admission history was important, only 30% reported doing this. Residents (26%) also felt that sitting would make the patient encounter longer, even though there was no difference in reported time completing an admission history between those who reported sitting and those who reported standing ($t=-1.38$, $p=0.17$). Therefore, an educational campaign entitled "S.I.T: Seeing I to Eye Together" was designed with the following teaching points: 1) Sitting increases patient perception of time spent at the bedside, 2) Sitting does not increase actual bedside time, and 3) Sitting enhances patient adherence and satisfaction, as well as physician communication. Education was disseminated through flyers and peer-led didactic presentations. Additionally, since 69% of residents felt sitting during attending-led rounds is important, attending physicians were asked to emphasize the teaching points during teaching rounds on inpatient Internal Medicine teams.

CONCLUSIONS: Survey results confirmed expected knowledge deficits, specifically as they pertained to time as a barrier to patient-physician communication. The learning objectives of the "S.I.T." educational campaign may address a key deficit in Internal Medicine resident education related to optimizing physician-patient communication through sitting and, further, has larger implications for improving hospital performance on patient satisfaction.

SEEING I TO EYE TOGETHER: AN EDUCATIONAL CAMPAIGN DESIGNED TO IMPROVE PHYSICIAN-PATIENT COMMUNICATION AMONG INTERNAL MEDICINE RESIDENTS

SEEKING APPLES, FINDING ORANGES: MISMATCH BETWEEN PERCEIVED BARRIERS AND GENERATED SOLUTIONS DURING THE SCOPING OF TWO CLINICAL INITIATIVES

Eli Cahan¹; Cati Brown-Johnson¹; Nadia Safaeinili¹; Kimberly Brunisholz²; Brenda Reiss-Brennan²; Marcy Winget¹. ¹Stanford University Medical School, Stanford, CA; ²Intermountain, Salt Lake City, UT. (Control ID #3185499)

BACKGROUND: Across disciplines, nearly two-thirds of efforts devoted towards organizational change fail. In healthcare, uptake of research to the clinic takes over a quarter-century, at which point significant deviations from study protocols are often required. As a result, even following uptake, patients may receive only half of recommended services, and interventions received often demonstrate low clinical response rates. The Consolidated Framework for Implementation Research (CFIR), developed to facilitate uptake of new services, defines domains salient to successful integration including features of the clinical and institutional environments, as well as individual providers. It is not clear that organizations experience barriers or generate solutions with equal frequency across domains. We characterized expected barriers and solutions proposed when preparing for implementation of two distinct initiatives across two healthcare systems.

METHODS: Initiatives for early treatment of (a) substance use and (b) physical therapy were scoped conceptually at six primary care clinics across one academic and one non-academic health system. Before introducing these initiatives, qualitative assessments of barriers to implementation were captured via interviews with clinic staff and providers. Ideas to facilitate implementation were solicited. Feedback was coded into six thematic categories, addressing: connectivity, workflow, internal resources (such as site-specific care protocols), external resources (such as system-wide electronic resources), teamwork/culture, and individual mindset. Percentages of comments on perceived barriers and ideas proposed were calculated for each of these categories.

RESULTS: For substance use treatment, 26% of barriers reported were workflow related, 16% involved internal resources, 22% involved external resources, and 22% related to individual mindsets. 40% and 30% of solutions addressed workflow and internal resources respectively, however only a combined 15% of solutions related to external resources and mindsets. Similarly, for physical therapy, while 49% of barriers arose from external resources and mindsets, only 13% of proposed solutions addressed these categories. Meanwhile, 73% of solutions addressed the 36% of problems arising from barriers in workflow and internal resources.

CONCLUSIONS: Organization of qualitative feedback following conceptual introduction of two clinical initiatives revealed a mismatch between perceived barriers and proposed solutions to implementation. While expected barriers were fairly evenly distributed amongst 4 key categories, solutions proposed by clinic providers and staff disproportionately addressed workflow and internal resources rather than mindsets and external resources. Observation of distribution and mismatch between perceived barriers and solutions can help inform institutional

interventions to facilitate implementation of new initiatives.

SELF-WEIGHING FREQUENCY AND ASSOCIATED CHARACTERISTICS AMONG VETERANS OF THE WARS IN IRAQ AND AFGHANISTAN.

Carolyn Bramante¹; Anne Joseph¹; Jennifer A. Linde¹; Charles J. Billington²; Steven Fu³; Rachel Widome¹. ¹University of Minnesota, Minneapolis, MN; ²Minneapolis VA Medical Center, Minneapolis, MN; ³Minneapolis VA Health Care System, Minneapolis, MN. (Control ID #3185915)

BACKGROUND: Rates of obesity are high among Operation Enduring Freedom/Operation Iraqi Freedom (OEF/OIF) Veterans. Self-weighing is a promising tool for weight loss and maintenance. Daily self-weighing at home can promote weight loss, likely by raising one's awareness of current body weight and behaviors associated with excess caloric intake. Multiple professional organizations recommend that clinicians advise patients to weigh themselves regularly for management of obesity and overweight. Our objective was to determine the frequency that OEF/OIF Veterans report engaging in self-weighing, and to explore demographic, behavioral, and mental health correlates of self-weighing.

METHODS: A random sample of 2,000 OEF/OIF veterans who had interacted with the Minneapolis VA Health Care System were mailed surveys about health-related behaviors in 2012. We conducted a retrospective analysis of this cross-sectional survey dataset. Our outcome of interest was the answer to "During the past 30 days, how many times did you weigh yourself?" We explored correlates using univariate analyses (t-test for continuous variables and chi² tests for categorical variables), and examined associations between self-weighing and income, body mass index, health behaviors, mental health indicators, weight satisfaction, with adjustment for age, gender, race, education, and employment status.

RESULTS: Of the 2,000 veterans who were mailed the survey, 953 (48%) responded, and 918 of these (96%) answered the question about self-weighing. Of the 918, 45% were female; 74% married; and 90% white, 5% black, and 5% "other." The mean age was 35 years, 44% had a college degree or more, and 62% were employed. Overall, 546 participants (59%) self-weighed less often than weekly; 153 (17%) self-weighed weekly; and 219 (24%) self-weighed more than once per week. In univariate analysis, respondents who self-weighed more than weekly were more likely to have a college degree or more (55%, p<0.01), more likely to be female (45%, p<0.01), less likely to report high satisfaction with weight (36%, p=0.03), and more likely to prepare meals with vegetables (77%, p<0.01). There were no statistically significant correlations between self-weighing and mental health indicators. In multivariate analysis, participants who prepared meals with vegetables were more likely to self-weigh more than weekly (OR 1.9, 95% CI 1.2-2.4), and there were no associations between self-weighing more than weekly and feeling downhearted, nervous, calm, or confident in one's ability to handle problems.

CONCLUSIONS: Most OEF/OIF veterans are not engaging in the important weight-management tool of self-weighing at least weekly. Stress and anxiety are often invoked as potential negative outcomes of self-weighing at home; however, we found no associations between self-weighing more than weekly and indicators of poor mental health in this cross-sectional survey. Self-weighing may be a behavior to encourage in this population for improved weight management.

SETTING HIGH STANDARDS FROM THE START: AN EXPERIENTIAL FACULTY ORIENTATION TO INTRODUCE INSTITUTIONAL EXPECTATIONS AROUND COMMUNICATION AND PATIENT SAFETY

Sondra Zabar¹; Mara McCrickard¹; Kinga Eliasz¹; Deborah Cooke¹; Katherine A. Hochman¹; Andrew B. Wallach^{1,2}. ¹NYU School of Medicine,

New York, NY; ²Bellevue Hospital, New York, NY. (Control ID #3185110)

BACKGROUND: Newly recruited clinicians have heterogeneous backgrounds and experiences and need a substantive introduction to their new institution's patient communication expectations and safety culture and standards for clinician performance. We describe a unique onboarding program designed to ensure that newly hired clinicians receive actionable, behaviorally specific feedback from the patients' perspective to support a satisfying transition to the new work environment, enhance patient experience and reduce the need to punitively react to complaints once they have started.

METHODS: During the 2-hour onboarding, participants complete 3, 10-minute Objective Structured Clinical Exam cases designed to assess how they address a medical error, manage the patient's discharge goals of care, and respond to an impaired learner. During each encounter, participants interact with highly trained Standardized Patients (SPs) or Standardized Learners (SLs) who use behaviorally-anchored checklists to evaluate provider performance on communication and case-specific skills. Following each encounter, participants complete a self-assessment while the SPs/SLs complete a behavior-specific checklist, after which the two discuss the encounter and the SL/SP provides confidential and actionable feedback. At the end, participants are encouraged to set individual learning goals to implement in their daily work, complete a program evaluation, and engage in a debrief with experienced facilitators. Participants also receive their SP checklists in addition to an institutional guide containing relevant resources and contacts.

RESULTS: Over 2 years, 57 faculty members representing 6 clinical sites participated in the onboarding program. They are heterogeneous with respect to general and case specific performance on these SP/SL cases. For example, 86% adequately elicited the SP/SLs story during the discharge case compared to 66% in the other two cases, 77% addressed pain management (a key patient goal), while 44% did not discuss important medication side effects. Participants have universally found this onboarding to be useful and relevant; 98% agreed/strongly agreed that the program was an effective way to reinforce good habits in patient and learner communication, 96% felt it enhanced confidence about their ability to communicate effectively, and 96% felt it reinforced the institutional culture of safety. All 56 participants who completed the evaluation agreed/strongly agreed that the event was engaging and well-designed, and 93% felt it was a good use of their time and would recommend the program.

CONCLUSIONS: Traditional orientations are not well recalled and do not address knowledge and skills in real-time. Although it requires additional resources, participants are enthusiastic about our low-stakes introduction to the institution's expectations. This program sets high standards and introduces a new model for skills-based onboarding which may lead to measurably improved patient outcomes.

SHOULD I STAY OR SHOULD I GO? INTER-RELATION BETWEEN JOB TURNOVER INTENTION, BURNOUT, WELL-BEING, AND JOB SATISFACTION

Shannon A. Scielzo; Rachel Bonnema; Ethan Halm. Univ of TX Southwestern Med Ctr, Dallas, TX. (Control ID #3184650)

BACKGROUND: Much attention has been paid to the rising epidemic of provider burnout and its adverse effects on the wellness of individuals and cost to health systems. Replacing a physician who leaves is estimated to cost \$500,000, so understanding the determinants of job turnover (not just burnout) and addressing them is paramount. While many factors are hypothesized to influence burnout, well-being, job satisfaction and job turnover, the empiric inter-relationship among these constructs, how to best measure them, and factors most strongly predictive of them is less well studied.

METHODS: An anonymous, web-survey was sent to providers in GIM, Med-Peds, Palliative Care and Geriatrics clinicians working in a large, urban academic medical center. The survey included demographics, the MiniZ burnout tool (including the 1 item burnout question (Mzb), 1 overall job satisfaction item (Sat), and 3 subcomponents, Meaning - M, Work-Life Balance - WLB, and Control/Influence -CI), Maslach Burnout Inventory

(MBI, subscales of Emotional Exhaustion - EE, Personal Accomplishment - PA, and Depersonalization - D), 1 item Well-Being Fuel Gauge (WBFG, a visual analogue scale from 'empty=0 to full tank=100') and job Turnover Intention (TI, plans to leave). Correlation matrices, factor analysis, and multiple regression was used to identify inter-relationships, factor structures, and independent predictors of TI, MZB, Sat, and WBFG.

RESULTS: Overall, 57% completed the survey (N=40; 75% MDs, 25% NPs). Overall MZ burnout was 35%, The mean WBFG was 64 out of 100; 62% of respondents were satisfied with their job, and 15% said they had plans to leave. Convergent validity was high with high correlations among MZB, MBI, WBFG, Sat, and TI measures ($r=.51$ to $.82$, $p<.01$). Multiple regression entering all constructs (MZB, WBFG, Sat, TI, EE, PA, D, CI, WLB) found that different outcomes had different independent predictors. For turnover intention and burnout, the most robust multivariable predictor was the Well-Being Fuel Gauge. For job satisfaction, it was control/influence. For the Well-Being Fuel Gauge, it was control/influence & Work Life Balance ($= 0.4$ to 0.5 and $p<.05$ for all).

CONCLUSIONS: The single item Well-Being Fuel Gauge was the best tool for predicting Turnover Intention and Burnout, exhibited excellent psychometric properties, and is easier to monitor more frequently than annual, multi-item burnout surveys. The primary drivers of Well-Being Fuel Gauge scores were Control/Influence and Work-Life Balance. Control/Influence also strongly influenced job satisfaction. Strategies to improve provider well-being and reduce turnover should target ways to bolster control/influence and work-life balance.

SIMPLE PREDICTORS OF MORTALITY IN ACUTE PANCREATITIS

Ashley M. Scott¹; Mohammad Baidoun¹; Naureen Farook^{1, 2}; Harold Gomez Acevedo¹; Sandeep K. Bhatti¹; Jeffrey Dueweke¹; Vidhya Nair¹; Hadi Mohammed¹; Angie Adhami¹; Guneet Ahluwalia¹; Sudarshan Hebbar²; Joseph Miller^{1, 2}. ¹Henry Ford Hospital, Detroit, MI; ²Calcimedica, La Jolla, CA. (Control ID #3178613)

BACKGROUND: Various historical studies have found that hypoxia portends a poor prognosis in patients hospitalized with acute pancreatitis. The objective of this study is to test early respiratory compromise on hospital presentation as a mortality predictor in acute pancreatitis. Secondary aims of the study were assessing prognostication abilities of the quick sequential organ failure assessment (qSOFA) and hypoalbuminemia in acute pancreatitis.

METHODS: This is a retrospective observational study based on adult patients hospitalized for acute pancreatitis. The data were collected from eight standalone emergency departments and five hospitals within Henry Ford Health System of Southeast Michigan. Patients with lipase levels less than three times the upper limit of the normal laboratory range were excluded. The primary outcome was inpatient mortality. Univariate and multivariate logistic regression was performed to determine predictors of adverse outcomes. The main variable of interest was respiratory compromise, defined as an initial SpO₂ of 92% on presentation. We combined other key variables on presentation to derive an area under the curve (AUC) for predicting mortality.

RESULTS: The study included 2,090 patients, mean age 55.5 years (SD 17.5) and 51.5% female. The median presenting lipase was 976 U/L (IQR 281-2500). Death was uncommon (n=34, 1.6%). Via univariate analysis, highly significant predictors of mortality were SpO₂ 92%, qSOFA score 2, and low albumin. Patients with a presenting SpO₂ 92% had 9.2% mortality, in contrast to a 1.3% mortality rate among those with an SpO₂ above 92% on presentation (OR 7.5, 95% CI 3.1-17.7). Those with a qSOFA score 2 suffered 9.8% mortality, compared to an average 1.3% mortality rate among those with a qSOFA of 0 or 1 (OR 8.6, 95% CI 3.9-18.9). Adjusting for age, gender, race, leukocytosis, hematocrit, and major comorbidities, qSOFA 2 remained a significant predictor of mortality (OR 2.6, 95% CI 1.7-4.1, $p<0.001$). Low albumin (OR 2.7, 95% CI 1.2-6.2, $p=0.02$) and SpO₂ 92% (OR 2.6, 95% CI 1.0-7.1, $p=0.05$) also remained significant predictors. By combining qSOFA with the presence of low albumin and SpO₂ 92% into a novel early acute

pancreatitis score (EAPS), the EAPS score had good accuracy for predicting mortality (AUC 0.80, 95% CI 0.72-0.89).

CONCLUSIONS: Independent predictors of mortality on initial presentation include low albumin, SpO₂ 92%, and a qSOFA score 2. Perhaps these simple prognosticators can guide clinical practice by more precisely identifying those with acute pancreatitis who are more critically ill and could benefit from closer monitoring.

SMOKING CHARACTERISTICS AND QUIT BEHAVIORS AMONG HEALTH CENTER ATTENDEES WITH SUBSTANCE USE DISORDERS: A NATIONAL STUDY

Danielle R. Fine; Benjamin Bearnot; Travis P. Baggett. Massachusetts General Hospital, Boston, MA. (Control ID #3169220)

BACKGROUND: Despite high smoking rates in patients with substance use disorders (SUDs), tobacco dependence in this vulnerable population has been undertreated. While current clinical practice guidelines recommend simultaneous treatment of substance use and tobacco dependence, there is limited research evaluating adherence to this guideline on a national level. The objectives of this study are to (1) describe smoking characteristics in patients with and without SUDs at US safety-net health centers, (2) assess differences in smoking-related quit behaviors between individuals with and without SUDs, and (3) evaluate the association between SUD treatment and receipt of advice to quit smoking.

METHODS: We analyzed data from 5,592 adult (18 years old) respondents to the 2014 Health Center Patient Survey, a nationally representative cross-sectional survey of individuals who receive care at federally funded health centers within the US. The main exposures were having a current alcohol use disorder (AUD) or drug use disorder (DUD) based on responses to the Alcohol, Smoking, and Substance Involvement Screening Test (ASSIST). We first evaluated smoking characteristics (frequencies of being a current or former smoker) in those with and without AUD and DUD. We then performed multivariable logistic regression to assess the relationship between AUD/DUD and smoking-related quit behaviors (past-year desire to quit, past-year quit attempt, plans to quit in the next 6 months, and being a former smoker among ever smokers [i.e. quit ratio]), and to evaluate the association between past-year AUD/DUD treatment and receipt of advice to quit smoking.

RESULTS: Sixty-four percent of health center patients with AUD and 55% with DUD were current smokers compared to 25% and 27% without AUD and DUD, respectively. Among lifetime ever-smokers, those with AUD were significantly less likely to be former smokers than those without AUD (adjusted odds ratio [aOR]=0.30; 95% confidence interval [CI]=0.14, 0.65). Current smokers with AUD had higher odds of wanting to quit smoking in the past year (aOR=2.88; 95% CI=1.19, 7.05) but were not more likely to have made a past-year quit attempt (aOR=1.02; 95% CI=0.57, 1.84). Additionally, there was no association between AUD or DUD and plans to quit smoking in the next 6 months (aOR=1.09; 95% CI=0.49, 2.42; aOR=0.63; 95% CI=0.25, 1.58, respectively). Smokers with SUD who engaged in AUD treatment (aOR=0.31; 95% CI=0.05, 2.01) or DUD treatment (aOR=0.97; 95% CI=0.21, 4.44) in the past year were not more likely to have received advice to quit smoking.

CONCLUSIONS: Consistent with prior research, individuals with SUDs had high smoking rates, and smokers with AUD had a higher desire to quit smoking but a lower quit ratio than those without AUD. SUD treatment did not increase the likelihood of receiving advice to quit smoking. These findings suggest a missed opportunity to provide tobacco cessation counseling during SUD treatment as recommended by clinical practice guidelines.

SOCIAL DETERMINANTS OF HEALTH AND MISSED CLINIC VISITS: FACTORS UNDERLYING WASTED RESOURCES IN VA AMBULATORY CARE?

Charlie M. Wray^{1, 2}; Marzieh Vali³; Amy L. Byers^{1, 2}; Salomeh Keyhani⁴. ¹University of California, San Francisco, San Francisco, CA; ²San Francisco VA Medical Center, San Francisco, CA;

³NCIRE, San Francisco, CA; ⁴University of California at San Francisco, San Francisco, CA. (Control ID #3185022)

BACKGROUND: Medical access failures, specifically missed clinic visits (MCV), are a significant resource drain on the Veterans Health Administration (VA). The VA reports that 15-18% of scheduled primary care appointments (~3 times higher than in the private sector) are not completed. VA strategic goals include improving the timeliness and effectiveness of care – with missed clinic visits representing a high-priority area. While previous appointment history, and patient demographics are shown to be associated with patients' propensity to 'no-show', no previous work has examined the association of social determinants of health (SDOH) with MCV. Our goal was to assess the association of four SDOH (lives alone, lack of social support, substance abuse and marginal housing) with MCV among Veterans hospitalized for congestive heart failure (CHF).

METHODS: We randomly identified 1500 elderly (65 and older) Veterans hospitalized with a primary diagnosis of CHF in 2012. SDOH were identified and extracted through chart abstraction. We determined the number of MCV (primary care, general internal medicine, geriatrics, and cardiology) in the year prior to admission. MCV were dichotomized into: 1 and 2 MCV. Multivariate logistic regression was used to examine the effect of the four SDOH on MCV rate; adjusting for age, psychiatric disorders, and the other SDOH.

RESULTS: Of the 1500 patients, 1282 (85%) had 1, while 218 (14%) had 2 MCV. Patients with 2 MCV had higher prevalence of all four SDOH compared to those with 1 MCV, while psychiatric disorders were equally present in both groups. In multivariate analysis, living alone (OR 1.71, 95%CI 1.21-2.41), marginal housing (OR 6.93, 95%CI 2.88-17.38), a history of substance abuse (OR 1.48, 95%CI 1.01-2.12) were significantly associated with having 2 MCV than patients without these risk factors. Higher age was associated with a lower risk (OR 0.96, 95%CI 0.94-0.98) of having 2 MCV.

CONCLUSIONS: SDOH are more common among Veterans who have high MCV rates in the VA. Primary care redesign strategies tailored to Veterans with a higher burden of SDOH may help improve delivery of care, reduce wasted resources, and improve access to care for all Veterans.

SOCIAL ISOLATION, LONELINESS, AND VIOLENCE EXPOSURE IN OLDER ADULTS

Elizabeth L. Tung; Kathleen A. Cagney; Louise C. Hawkley; Monica E. Peek. University of Chicago, Chicago, IL. (Control ID #3177732)

BACKGROUND: Social isolation, a key predictor of mortality in the

Characteristics and Missed Clinic Visit Outcomes in Veterans 65 and older Hospitalized for Congestive Heart Failure

| Descriptive Characteristics | | | |
|-----------------------------|--------------------------------|--------------------|------------------|
| | Prevalence among cohort | ≤1 MCV, (N=1282) | ≥2 MCV, (N=218) |
| Age, years ($\pm SD$) | -- | 78 (± 8.7) | 75 (± 7.9) |
| Lives Alone | 19% | 225 (18%) | 58 (26%) |
| Marginal Housing | 1.5% | 9 (<1%) | 14 (6%) |
| Substance Abuse | 16% | 179 (14%) | 53 (24%) |
| Lacks Social Support | <1% | 7 (<1%) | 5 (2%) |
| Psychiatric Disorders | 25% | 323 (25%) | 54 (25%) |
| Multivariate Analysis | | | |
| | Odds of ≥2 Missed Clinic Visit | | |
| | Unadjusted Analysis | Adjusted Analysis | |
| Age | *0.96 (0.94-0.97) | *0.96 (0.94-0.98) | |
| Lives Alone | *1.70 (1.21-2.36) | *1.71 (1.21-2.41) | |
| Marginal Housing | *9.68 (4.19-23.52) | *6.93 (2.88-17.38) | |
| Substance Abuse | *1.97 (1.39-2.78) | *1.48 (1.01-2.12) | |
| Lacks Social Support | *4.27 (1.25-13.49) | 2.21 (0.54-8.04) | |
| Psychiatric Disorders | 0.97 (0.69-1.37) | 0.91 (0.64-1.27) | |

Notes: *indicates P<0.05, multivariate analysis controlled for age, psychiatric disorders, and other SDOH covariates. Substance abuse includes: Alcohol or Drug Abuse

U.S., may be heightened in communities affected by violence. For instance, qualitative studies have documented that older adults who live in high-crime communities often report confinement to their homes due to safety concerns. However, few studies have quantified associations between social isolation and community violence exposure in at-risk populations.

METHODS: Adult patients (N=506) were recruited from clinics in 2 epicenters of violent crime in Chicago, and surveyed using computer-assisted personal interviewing software. Social isolation was measured using validated items for social network characteristics, living arrangements, social participation, social support, and loneliness; all measures were normalized to 100-point scales. Lifetime violence exposure was measured using the Brief Trauma Questionnaire, which queried participants about being a direct victim of violence, a witness to violence, or a close friend/family member of someone who died violently. We used generalized linear models to assess social isolation measures as a function of violence exposure, controlling for age, gender, race/ethnicity, education, insurance, and employment. We also used identical model specifications to assess health behaviors as a function of above- or below-average loneliness scores.

RESULTS: Mean age was 59.6 ± 13.0 years. Participants were predominantly female (71%) and non-Hispanic black (75%). Two-thirds reported a prior exposure to community violence (62%), either as a direct victim (41%) or as an indirect witness, friend, or family member (49%). Prior exposure to community violence was associated with a 7.8-point reduction (95% CI, -13.2 to -2.5) in perceived social support from friends; a reduction in perceived social support from family was not significant. Although mean social network size was similar between exposed (2.4 ± 1.7 persons) and unexposed groups (2.2 ± 1.7 persons), prior exposure to community violence was associated with a 8.0-point increase in perceived loneliness (95% CI, 3.5 to 12.4). Living arrangement and social participation did not differ between groups. An above-average loneliness score was associated with fewer days per week of fresh fruit and vegetable consumption (-0.5 days; 95% CI, -1.0 to -0.1) and medication adherence (-0.6 days; 95% CI, -1.0 to -0.2); and more days per week of binge alcohol consumption (0.4 days; 95% CI, 0.1 to 0.6) and using tobacco products (0.5 days; 95% CI, 0.1 to 0.9). Physical activity did not differ between groups.

CONCLUSIONS: Exposure to community violence was associated with less social support and higher loneliness in this high-risk sample of urban-dwelling adults; loneliness was associated with adverse health behaviors. At a time when public health leaders are calling for solutions to the "epidemic of loneliness," identifying populations at highest risk for loneliness may help to target interventions and ensure equitable access to social and medical support.

SOCIAL NETWORK ANALYSIS OF FIREARM SHARING AMONG US STATES

Sae Takada^{1, 2}; Kristen Choi¹; Shaw Natsui¹; Altaf Saadi¹; Liza Buchbinder^{1, 2}; Molly C. Easterlin^{1, 3}; Frederick Zimmerman⁴. ¹UCLA National Clinician Scholars Program, Los Angeles, CA; ²U.S. Department of Veterans Affairs, Los Angeles, CA; ³Cedars Sinai Medical Center, Los Angeles, CA; ⁴UCLA Fielding School of Public Health, Los Angeles, CA. (Control ID #3185910)

BACKGROUND: There is growing concern that the movement of firearms across state lines may decrease the effectiveness of state-level firearm-restricting policies. Yet how firearms cross state lines and how state-level firearm policies affect cross-state movement have not yet been widely explored. The purpose of this study was to characterize the flow of firearms between states in a social network analysis and examine how state-level firearm policies affect level of firearm movement.

METHODS: We used the Bureau of Alcohol, Tobacco, Firearms, and Explosives firearm trace data from 2012 to 2016 to create a network of firearm flow between states, defined according to "origin states" (state where a given firearm is purchased) and "destination states" (state where a given firearm is recovered). We used social network analysis and considered these networks at three thresholds of firearm flow: at least 1, at least 50, and

at least 100 firearms per year. The study examined all 50 states in the United States, excluding the District of Columbia and US territories. For each state, we calculated the number of destination states for which it served as the origin state, as well as the number of origin states for which it served as the destination state. We used fixed effects linear regression models to explore the relationship between the number of states for which a given state was the origin of firearms and state-level firearm policy, adjusting for poverty rate, population density, and hunting license rate as a proxy for gun ownership. We used a similar model to examine the relationship between the number of states for which a given state was the destination of firearms.

RESULTS: Over the 5-year period, in an average state, firearms recovered were traced back to 41 outside origin states. States served as the destination for firearms from as few as 16 origin states (Vermont) to as many as all 50 states (California and Florida). States served as the origin for firearms for as few as 18 states (Rhode Island) and as many as all 50 states (California). In a regression controlling for the other covariates, the number of states for which a given state served as the origin was negatively associated with the number of restrictive firearm policies in the state, while the number of states for which it served as the destination was positively associated with the restrictive firearm policies in the state.

CONCLUSIONS: States with a greater number of restrictive firearm policies were more often destinations of firearms from outside states. The same states were less often the origin of firearms recovered in outside states. State-level firearm policies may not sufficiently address firearms that cross state lines. The effectiveness of firearm-restricting policies at the state level is complicated by a network of firearm sharing among states. Without national policy solutions, the impact of state-level restrictions on firearms may be muted.

SOCIAL NETWORK CHARACTERISTICS AND OBESITY-RELATED BEHAVIOR AMONG HISPANIC IMMIGRANTS

Jane W. Njenu; Mark L. Wieland; Janet Okamoto; Paul J. Novotny; Luz Molina; Graciella Porraz-Capetillo; Irene G. Sia. Mayo Clinic, Rochester, MN. (Control ID #3182195)

BACKGROUND: Social networks influence behaviors through multiple mechanisms, including shared social activities and social support and are significant contributors to the obesity epidemic. Social network interventions targeting behavior change leverage these mechanisms. Social networks and obesity-related behaviors have not been described yet among Hispanic immigrant groups in the US. The overall goal of this study was to describe social networks and obesity-related characteristics among Hispanic immigrants in a mid-size Midwest US city, to inform a community based participatory research-derived nutrition and physical activity social network intervention, targeting behavior change to decrease obesity rates and cardiovascular risk.

METHODS: Setting and Participants: Hispanic immigrants in a mid-size city in SE MN Data collection: Conducted by bilingual study team members at community locations Measures: Demographics, general health measures, biometric (BMI), socio-behavioral and network measures Data analysis: Descriptive statistics were used to report the survey and biometric data. Logistic models were used to describe the basic associations of participants and network demographics with binary characteristics such as being overweight or being likely to lose weight. Network data was analyzed to identify nodes and ties and visualize the network. UciNet, Gephi, and R were used to calculate network metrics, conduct more complex network analysis and to visualize the social network.

RESULTS: Of the 610 Hispanic participants, 81% were overweight/obese. The network had 1,998 named nodes with 2,354 ties between these nodes. Modularity of the network was high at 0.94. 32% of named alters were perceived to be overweight/obese. Compared to normal weight respondents, the mean percentage of overweight/obese network members was higher for overweight/obese respondents (33.7% vs. 28.7%, P=<0.001). Participants who stated that they were likely to lose weight reported more positive social norms for obesity [mean (SD)] 2.4 (0.8) vs. 1.5 (0.8), P=<0.0001), social support (3.2 (1.1) vs. 2.6 (1.2), P=<0.0001), and more social cohesion (3.3 (1.4) vs. 3 (1.3), P=0.008) than participants

who were not likely to lose weight. Findings were similar for participants whose social contacts were trying to lose weight compared to participants whose social contacts were not. If most or all of overweight/obese participant's social contacts were trying to lose weight the odds of stating they were likely or very likely to lose weight was four times higher compared to other participants (OR 4, CI 2.2-7.2).

CONCLUSIONS: In this community, obesity, obesogenic behaviors, weight loss intentions, social norms for weight loss and social support clustered by ascertainable networks. A social network intervention targeting behavior change for weight loss is feasible.

SOCIAL SERVICE TOUCHPOINTS AS OPPORTUNITIES TO SCREEN WOMEN AT HIGH RISK FOR TYPE 2 DIABETES

Maya S. Venkataramani; Nisa Maruthur. Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #3184578)

BACKGROUND: Women with a history of gestational diabetes are at increased risk for type 2 diabetes, but many do not receive recommended testing for diabetes following pregnancy, in part due to limited interactions with the healthcare system. This is particularly true for low-income women. These women may have more regular contact with social service providers, including Head Start and WIC. Leveraging contact with these services could provide an opportunity to reach these women to enhance awareness of risk and encourage testing. We examined the proportion of mothers with gestational diabetes who accessed WIC or Head Start services who had not received recent diabetes screening.

METHODS: We analyzed data from the 2016 and 2017 National Health Interview Survey. Our analytic sample consisted of sample females ages 18 to 45, linked to at least one child (age 17 or younger). We excluded women with a diagnosis of diabetes or prediabetes. We analyzed 2 groups: 1) those who received WIC services/had a child who received WIC (in the past calendar year); and 2) those with a child currently enrolled in Head Start. In each group, we characterized the prevalence of self-reported gestational diabetes, and the proportion of these women who had diabetes testing in the past 3 years. As women may have reported testing associated with pregnancy, we conducted sensitivity analyses using a definition of recent screening that could exclude testing during pregnancy (e.g, within 2 years if the youngest child was 2).

RESULTS: A total of 6661 (29,628,017 weighted) women between the ages of 18 and 45 could be linked to a child; 90.8% (26,890,789 weighted) did not report a history of diabetes or prediabetes. Among these women, 16.2% (937 unweighted; 4,343,424 weighted) reported WIC receipt for either themselves or their child. 7.5% (456 unweighted; 2,016,894) had a child currently enrolled in Head Start. (2.5% reported both). Among women who had accessed WIC, 10.6% reported a history of gestational diabetes. 9.9% of these women did not report recent diabetes screening. 8.8% with a child in Head Start reported a history of gestational diabetes, and 8.2% of these women did not have testing within 3 years. In sensitivity analyses that could exclude recent pregnancy related testing, 35.0% (in WIC) and 21.2% (in Head Start) did not report recent screening.

CONCLUSIONS: About 1 in 12 women with a history of gestational diabetes and recent contact with WIC or Head Start had not been screened for diabetes in the past 3 years, and this proportion maybe 3 to 4-fold higher (if self-report included pregnancy-related testing). More precise estimates are difficult to ascertain due to limitations in pinpointing if testing occurred during pregnancy and the use of self-reported measure. However, the results suggest that leveraging contact with these programs could enhance appropriate follow-up among low-income, high-risk women who may have limited interactions with the healthcare system.

SOCIODEMOGRAPHIC CHARACTERISTICS OF PATIENTS WHO USE HUMAN VERSUS ANALOGUE INSULIN IN A NATIONALLY REPRESENTATIVE PATIENT SAMPLE

Alexandra M. Mapp; Jennifer N. Goldstein. Christiana Care Hospital, Newark, DE. (Control ID #3186403)
